The high field test apparatus SULTAN at the Paul Scherrer Institute (see photograph in *Nature* **336**, 338; 1988) consists of magnetic spools contributed by ENEA and ECN. The design of the facility and the cryogenic infrastructure was realized by the Paul Scherrer Institute. Euratom helped to finance both construction and running costs of the apparatus.

AAAS annual meeting draws largest crowd of decade

San Francisco

THE annual meeting of the American Association for the Advancement of Science (AAAS) in San Francisco drew nearly 10,000 scientists, journalists and members of the public, making it the largest, and according to its organizers, the most successful meeting of the decade.

But the annual meeting still lacks a clear identity, and efforts to move it closer to a mainstream scientific meeting were not an unqualified success.

Since a low of only 2,300 people attending the Los Angeles meeting in 1985, AAAS has worked hard to boost attendance at its meetings. One approach that outgoing AAAS president Walter Massey credits with attracting a broader audience to the meetings has been special scientific symposia. These symposia, requiring a separate registration fee, were first held three years ago. This year's symposia on plant molecular genetics and protein folding drew standing-room-only crowds in 500-seat ballrooms.

But in neighbouring rooms of equal size, scientific symposia covering similar basic science topics seemed empty by comparison. Twelve sessions over four days brought top scientists from around the country to San Francisco for sessions on cellular receptors, developmental biology and gene expression and retroviruses and oncogenes, but audiences were disappointingly small.

Corey Goodman, professor of biochemistry at the University of California at Berkeley, who co-organized the developmental biology session, says he was mortified to find only 60 or 70 people in a hall that holds 500 listening to a paper presented by Harvard's Philip Leder.

Goodman maintains that a similar talk would have drawn hundreds at any of the San Francisco area's research universities. Each of the scientific sessions had several scientific luminaries who would typically draw large crowds, but none was well attended.

Goodman also complains that after exhorting him to coax the best scientists to come to the meeting, often at their own expense, AAAS then did little or nothing to promote attendance at the sessions. Goodman says that others who were asked to organize special symposia were similarly disappointed by the results.

Massey says he is not sure why these sessions failed to attract larger audiences, and the problem will have to be sorted out before the next meeting.

The San Francisco meeting did have its own social issues. A polite demonstration by an AIDS activist group disrupted an awards ceremony for AIDS researcher Anthony Fauci, director of the National Institute of Allergy and Infectious Diseases.

Outside the meeting, animal rights activists distributed leaflets and held posters protesting at the use of animals for scientific research. The AIDS protesters threw confetti as part of their protest against the red tape involved in approving new AIDS drugs, said Massey, a stark con rast to the 1971 meeting in Philadelphia at which protesters threw blood in an anti-war protest.

The most controversial session of the current meeting occurred on the last day, when J. Philippe Rushton of the University of Western Ontario presented a paper using anatomical, genetic and behavioural studies as a basis for claiming that blacks exhibit less sexual restraint, have lower intelligence and have more violent temperaments than Caucasians or Asians. When news of the Rushton talk began circulating among the 771 journalists registered for the meeting, Massey was brought to a hurriedly scheduled press conference to deny that AAAS supported Rushton's theories, but to emphasize that it supported his right to express his opinion.

As an organization, AAAS is in the midst of change. In addition to the annual meeting, AAAS's most visible role is as publisher of *Science*. But the organization also has active programmes in public understanding of science, arms control and human rights. From 1975 until 1987, William Carey served as AAAS executive director, and with an insider's background in the workings of Washington, Carey put AAAS in the thick of the US science policy debates.

Carey was replaced by Alvin Trivelpiece, who had previously been an assistant secretary at the Department of Energy where he was widely credited with convincing President Reagan that he should approve plans to build the Super-conducting Super Collider.

But Trivelpiece resigned late last year to become director of the Department of Energy's Oak Ridge National Laboratory. His leadership was too short to establish any clear direction for the organization. Former *Science* editor Philip Abelson is acting executive director while the search for a successor proceeds.

AAAS has embarked on a series of long-term reviews on where it has been and where it is going. Massey is confident that the annual meetings will regain much of the vitality they had in the 1960s and early 1970s, when AAAS became a focus for the intersection of science and society.

Nuclear plant presents unique problems

Boston

THE first attempt ever to decommission a commercial nuclear power plant reached a crucial milestone last month when the reactor vessel of the Shippingport Atomic Power Station was hoisted out of its underground site. The reactor's removal is perhaps the largest single step in the Energy Department's five-year, $98-million project to decommission the power plant, located outside Pittsburgh, Pennsylvania, but many steps still remain.

Built in 1957 as part of the "Atoms for Peace" programme, Shippingport was the world's first nuclear plant to operate solely for the production of electricity. It closed in 1982, and work on dismantling it has been going on for three years.

The 72-MW reactor was constructed in a joint venture between the now-defunct Atomic Energy Commission (AEC) and a private utility, and the government agreed at the time of its construction to take charge of its decommissioning.

All other US commercial reactors will have to be decommissioned by the utility companies that built them, focusing industry interest on the Shippingport project. In the United States, 15 plants are expected to be ready for decommissioning by the year 2000.

The Department of Energy (DoE) wants to use the Shippingport reactor as a model programme for decommissioning. But some critics say that experience gained at Shippingport will have limited relevance to future decommissioning, and will only emphasize the obstacles others will face.

The most glaring obstacle is that in the United States there is still no high-level nuclear waste repository for spent fuel rods from commercial reactors, and virtually no place to deposit low-level waste. All three of the existing low-level facilities are close to capacity and nearing the end of their designed life-spans. For commercial reactors now and in the foreseeable future, disposal of radioactive refuse from a decommissioned plant would be impossible.

But even beyond the disposal problem, critics say that DoE is not making as much of the exercise as it could for testing and evaluating techniques needed in the future. They also object to DoE's decision to remove the reactor vessel for disposal in its entirety rather than cutting it into pieces on site as will be necessary for larger plants. Even with the reactor vessel's removal, the job is far from over. On the Shippingport site, two more years of work are expected.

Seth Shulman

Soviet nuclear power plant programme marks time

Moscow

THE sad accident at Chernobyl three years ago has cast a shadow on the nuclear power programme of the Soviet Union. Although the Minister of Nuclear Power Engineering, Mr Nikolai Lukonin, has only recently reaffirmed the government's commitment to nuclear generation as a means of meeting growing electricity needs, planned nuclear developments are now being resisted vigorously by the public and by local authorities in some republics.

The decision to close the two reactors of the Armenian nuclear plant near Yerevan, after a reassessment of the seismic hazards following last month's earthquake, is a further aggravation of the problems. One reactor will be closed on 25 February, the second on 18 March, after the expected peak of winter electricity consumption. Electricity supply in the Georgian republic will afterwards be tightly constrained.

Growth of nuclear generation capacity has been practically zero over the past year, with 45 reactors at 16 sites with a total generating capacity of 34.4 GW. Total generation last year, at 215 GWh, was 12.7 per cent of electricity consumption. But although new capacity is under construction at 15 sites, the building programme has been substantially pruned. A total capacity of 28 GW has thus been lost.

Nuclear construction projects have been stopped in Azerbaijan, Georgia, Armenia, Lithuania, Byelorussia, the Ukraine and in the south of the Russian Federation. And it can be confidently presumed that further nuclear power stations will be vetoed.

These developments create an awkward predicament for the Ministry of Nuclear Power Engineering, formed after the Chernobyl accident with responsibility for eradicating the consequences of the accident. The ministry is retraining personnel at all nuclear plants, revising construction and operating standards and improving safety arrangements. Lukonin now acknowledges a need for greater openness, and an open dialogue with the public. Trust is easily lost, but regained only with difficulty.

The Soviet government's decision to invite the international Operational Safety Review Team (OSART) to the Soviet Union for three weeks in December is part of the process of regaining trust. The team, including staff members of the International Atomic Energy Agency (IAEA) and independent experts from a dozen countries, made a detailed examination of the 1,000-MW pressurized water reactor at the Rovno power station in the Ukraine.

The preliminary conclusions, given at a press conference in Moscow by Ferdinand Franzen and Morris Rosen, respectively head of the IAEA safety division and director of nuclear safety, are generally positive. The group acknowledged the competence of the operating staff, the priority given to safety (hardly surprising after Chernobyl) and that radiation shielding and ecological aspects of the plant's operation were up to international standards.

Among shortcomings at the Rovno plant, the group draws attention to the poor quality of some of the equipment arriving there (whose defects must be made good on site) and shortages of some modern instruments and automatic devices. The OSART team also plans to recommend in its final report that the station's senior executives should be given more decision-making power.

Lukonin says that his ministry is taking steps to toughen requirements for site selection, the supervision of construction and the acceptance of equipment, while the ministry responsible for instruments says that it is making good the shortages which have been noted. The recommendation that station managers should have more authority, meant to secure greater flexibility over decisions, would presumably also encourage them to act more responsibly: Chernobyl showed that the over-meticulous tutelage of the higher authorities breeds complacency.

The immediate effect of the OSART mission on Soviet public opinion will be to demonstrate the government's readiness to follow the highest international standards in the operation of nuclear plants. There have already been similar inspections of 29 reactors in 16 countries, presumably with similar effects. The next inspection in the Soviet Union will be of the two 500-MW heat-supply reactors being built at Gorky.

More turmoil at German universities

Munich

DESPITE government approval in December of an emergency aid programme for the overcrowded West German universities (see *Nature* 336, 704; 22/29 December 1988), demonstrations and strikes continued after the Christmas vacation.

The situation in Berlin, where the president of the Free University had to call for police help to keep open laboratories in the medical faculty, seems to be the most serious. Students there who were not on strike had complained that they were being deprived of their right to study. Most medical students have since returned to classes, but students in other faculties remain on strike, demanding more say in governing the university and an improvement in the abysmal conditions caused by overcrowding.

There have been demonstrations and strikes at other universities in West Germany. In Munich, more than 30,000 students from both the Technical University and the Ludwig-Maximilian-University marched peacefully through the middle of the town demanding more low-cost student housing, more professors, more student grants and loans and the construction of a long-discussed subway line to the campus at Garching.

All parties in the Bundestag (parliament) called on 18 January for "relief" of the overcrowding, but without being specific. West German Education Minister Jürgen Möllemann (Free Democrat) said he would try to persuade the cabinet to add DM400 million to the DM2,100 million emergency programme voted in December.

Steven Dickman

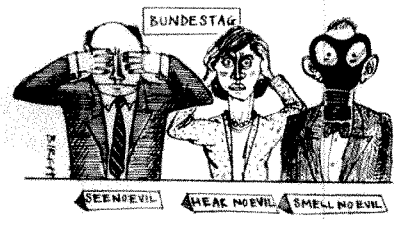
Stock Exchange tries to stop research leaks

London

LEAKING to the financial markets of information in medical journals before their publication is causing concern in the London Stock Exchange. Results in the *British Medical Journal* (BMJ) of a report favourable to Glaxo's Zantac were leaked the day before publication, causing the company's share price to increase unexpectedly and more than 3 million shares to be traded that day. An investigation of the incident was initiated by the Stock Exchange's surveillance unit; no evidence of insider dealing was found.

Since then, the Stock Exchange has been considering how such incidents might be avoided. One proposal is that drug companies be asked to inform the Stock Exchange if information about to be published is price-sensitive; notice of this would then be released on the Stock Exchange's news service before publication.

At present, pre-publication copies are issued to journalists; this information is often leaked to analysts when journalists ask for comment on new results. The BMJ this month warned journalists receiving advance copies that it will not continue to supply copies to journalists found to have disclosed any information before publication. Analysts would prefer to receive information at the same time as journalists, but that will not put an end to leaking. It is the analysts' job, said one, to find out what is not in the public domain and to use that information.



Christine McGourty

West Germany admits it knew of Libyan chemical plant

Paris

MORE evidence emerged last week that West German companies have been involved in the construction of an alleged chemical arms plant at Rabta, Libya, bringing a vigorous attack in the West German Bundestag (parliament) on 18 January of the federal government's handling of the affair.

Chancellor Helmut Kohl was accused of damaging West Germany's relationship with the United States, bringing shame upon the Bundestag, prolonging the threat of chemical arms and covering up the involvement of West German companies in their manufacture.

For seven months, Kohl's government had shrugged off increasingly noisy US claims that Libya was building a chemical arms factory, and that West German companies were involved (see *Nature* **337**, 199; 19 January 1989). But last week Chancellery chief Wolfgang Schäuble admitted to the Bundestag that both allegations were justified.

Schäuble confirmed that the government had been aware since May 1988 of the possible involvement of West German companies in building and supplying the factory. But he defended the government's silence, saying that customs investigations of one company, Imhausen-Chemie GmbH, had failed to produce sufficient evidence for a prosecution.

Last July, West German customs officials were warned by foreign intelligence agencies that a Frankfurt-based company, Ihsan Barbouti International (IBI), was suspected of engineering an illegal supply route to divert construction materials and chemicals to Libya. But it is only this year that documents seized from IBI offices have confirmed the clandestine operations. The company is now in liquidation.

IBI, set up by Iraqi businessman Ihsan Barbouti, used a Hong Kong company that was also linked with Imhausen-Chemie to obtain legitimate export licences. But cargoes that included architectural plans from Imhausen-Chemie and ventilation equipment and dichloroethane from two other German suppliers were diverted to Libya.

Legal action is now being taken against IBI for falsification of export documents. But it is still uncertain whether the suppliers, including Imhausen-Chemie, Merck and Alfred Tewes GmbH, actually broke the law.

Despite tighter controls, the volume of export trade — about 2.5 million shipments a month from West Germany — makes it impossible to halt illegal trading completely. Now other governments are looking to see if they can point an untainted finger at West Germany.

Peter Coles

Japan denies involvement in Libya

Tokyo

JAPAN's Foreign Ministry has firmly denied a US claim that two Japanese companies provided Libya with equipment for a chemical weapons plant. According to the spokesman, Yoshifumi Matsuda, the disputed "metallurgical complex" built in Libya by Japan Steel Works was designed to produce parts for a water purification plant, not shells for chemical weapons as had been claimed.

Allegations about Japan Steel Works and another company, Marubeni, hit the Japanese headlines last week after US Senator Jesse Helms included their names in a list of 36 companies, most of them West German, which he submitted to the Senate Foreign Relations Committee. All were alleged to have had links to the Libyan plant.

But Matsuda says that Senator Helms's list is based only on newspaper articles. In December, the *Christian Science Monitor* mentioned Japan Steel Works in an article on chemical warfare. The Ministry of International Trade and Industry (MITI) has since had time to investigate the allegations and found them to be untrue.

According to a MITI spokesman, a close watch is kept on products that might be used to build chemical weapons, and the export of nine key chemicals from Japan is prohibited without special licence.

Alun Anderson

AIDS test law

BULGARIA has introduced tough new legislation aimed at halting the spread of AIDS. Unlike other socialist countries, where anti-AIDS legislation concentrates on curbing the sexual activity of people known to be HIV-positive, the Bulgarian law concentrates on compulsory testing and treatment. Heavy fines will be imposed on those who refuse tests, and also "persons who do not fulfil their official duties in the fight against AIDS". V.R.

Another blow for creationism in California

Berkeley

THE California Board of Education has passed a policy statement on the teaching of science aimed at strengthening the message that evolution, not creationism, belongs in the science classroom. The statement supersedes a vague "antidogmatism policy" which often left teachers uncertain about how strongly they should stress evolution.

The antidogmatism statement, adopted in 1972 when Ronald Reagan was governor, was a brief directive on the discussion of "origins of life and earth", that required that "dogmatism be changed to conditional statements where speculation is offered as explanation for origins". California creationists, including members of the Institute for Creation Research in San Diego, have used the statement in their efforts to water down the teaching of evolution in California classrooms.

In 1981, a Superior Court judge decided against creationists in a case challenging the teaching of evolution as dogmatic. His decision affirmed that teaching of the scientific method is by definition not dogmatic, and that teaching of creation in public schools constitutes religious instruction, and is therefore constitutional.

But he upheld the antidogmatism policy as the ruler against which science education was to be measured. Scientists and teachers complained that the policy singled out the theory of evolution as somehow little more than conjecture, ignoring the true definition of a scientific theory and the fact that all science is based on theories that have stood the test of time. Many teachers, they said, felt compelled by the policy to couch their discussions of evolution in speculative terms.

The new policy statement carefully defines theories as tools of science, different from beliefs because they are logical constructs based on evidence, and subject to testing, modification and refutation. Beliefs, it implies, are closer to dogma, as they are based on ideology and not subject to test. A spokesman for the education board says that by requiring science teachers to teach only what falls within the definition of science, and directing administrators to support teachers in their resistance against pressure to do otherwise, the statement's drafters hope that it will provide firm support for science teachers who are put under pressure to teach creation in their classes.

The board is also planning to reject for use in California classrooms textbooks that do not deal adequately with evolution.

Marcia Barinaga

Lessons from eugenic history

SIR—Among the four papers on schizophrenia in the 10 November 1988 issue of *Nature*, there was one brief reference to an early work by the German psychiatric geneticist, Professor Ernst Rüdin[1,2]. Unfortunately, there was no discussion of Rüdin's work or his career, subjects painfully relevant to the topic of the inheritance of schizophrenia. Rüdin was an internationally recognized psychiatrist-geneticist whose field of interest was the genetics of schizophrenia. In 1928, he became director of the Kaiser-Wilhelm Institute of Psychiatry in Munich. Rüdin was one of the principal architects and advocates of the Nazi programme of enforced eugenic sterilization, which was an application of his work on the inheritance of psychiatric disorders. The programme saw the sterilization of about 50,000 German citizens a year, beginning in 1934. It established a 'scientific' basis for the mass control of reproduction with the objective of eliminating undesirable traits of human life that were considered to be hereditary[3]. Criteria for sterilization in Rüdin's institute included being a conscientious objector, a frame of mind that was considered to be a form of schizophrenia and consequently classified as hereditary[4].

Rüdin's genetic/eugenic fervour was not confined to compulsory sterilization. He was a supporter of the 1935 Nuremberg race laws, which he considered to have been an achievement for his eugenics movement[5]. He served as a member of a group of psychiatric 'expert witnesses' for the euthanasia programme of medicalized murder which, the 'experts' felt, would "meet with general understanding and approval, as it becomes established and more generally known that. . . all possible measures were taken either to cure the patients or to improve their state sufficiently to enable them to return to work which is economically worthwhile. . ."[6].

To the uninformed, psychiatry appears to be a naive 'Cinderella' specialty that is only now joining the ranks of experimental genetics. The reality is that psychiatry has been a wicked 'step-sister' in the field of experimental genetics, a nefarious role which Ernst Rüdin helped to define. What is new today is the sophistication of genetic research which enables science to explore the molecular basis of human heredity in a manner undreamed of in the days of Rüdin. What is still needed, however, is a process that ensures that human values are appropriately applied with a sensitivity and a sophistication that takes into consideration the recent history of science and medicine where values and science were distorted to the detriment of all mankind. By ignoring this history, science has demonstrated that it has yet to achieve the sensitivity required to pursue this type of research in a manner which is in the best interests of human society.

Suffer the animals

SIR—If G.E. Lamming's account of an international symposium on biotechnology in growth regulation (*Nature* **336**, 19–20; 1988) is comprehensive, as I have no doubt it is, it implies that the subject of animal welfare was not considered seriously at that symposium. The absence of a session on the welfare aspects of genetic engineering reinforces the impression that little more than lip service is being given to the humane aspects of what is a headlong rush for quick profits by the meat-production industry.

It is clear from observations of transgenic animals so far produced that they frequently develop unexpected abnormalities that cause them considerable suffering. Indeed, Lamming mentions that transgenic pigs made by researchers at the US Department of Agriculture suffered high mortality and morbidity.

Only an elementary knowledge of molecular genetics is necessary to predict that the random insertion of foreign DNA into an animal's genome is likely to cause abnormalities in at least some of the recipients that will lead to real suffering. It is important that those involved in the production of transgenics should be seen to be taking particular care over this aspect of their work, for example by including it on the agenda of international meetings.

Farewell Soil Bureau

SIR—As a result of an institutional rearrangement by the Department of Scientific and Industrial Research (DSIR), the New Zealand Soil Bureau has disappeared. After more than 50 years of carrying out soil research and providing soil maps, it has ceased to exist as an independent unit. Founded when the New Zealand economy depended almost entirely on the soil, it has succumbed t the new style of New Zealand life and th reforming zeal of the government.

Probably its greatest triumph was th detection of the lack of critical trac elements in volcanic soils, which allowe successful sheep farming over wid regions of the North Island; and mor recently the painstaking investigation c aspects of the Abbotsford landslid gained the admiration of the geotechnic community.

Soil science has now been incorporate into the new DSIR Division of Land an Soil Science, but the rationalization ha meant that more than 20 scientists hav lost their bureau jobs, including Benn Theng, Graham Claridge, Pauline McCo and Iain Campbell. Soil science in Ne Zealand has been diminished, as it has i the United Kingdom. It seems odd that a we become aware of major 'green' issues agencies directly involved with their inves tigation are closed.

Credit where it's due

SIR—In their 'anniversarial' article (*Nature* **337**, 29; 1988) W. F. Bynum and J. L. Heilbron, discussing the cell theory of the German botanist Theodor Schwann (1810–82), say that the famous phrase *Omnis cellula e cellula* "came later". Thus, by inference, they sustain the widely held but erroneous attribution to Rudolf Virchow (1821–1902).

In fact, and in print, it was first used by François-Vincent Raspail (1794–1878), as epigraph for his thesis "Développement de la fécule dans les organes de la fructification des cereales" (1825)[1], in which he refers specifically to the origin of new cells by division. The anatomist Matthias Schleiden (1804–81), Schwann, and later Virchow all appear to have lifted one or more of Raspail's prior contributions to the cell theory without acknowledging their source. The nationalistic nature of their behaviour is epitomized by a ringing declaration made in 1866 by the surgeon Pierre-Paul Broca (1824–80), that "the cell is French and belongs to M. Raspail", (quoted by Wiener, 1968)[2]. But Broca was correct. It is time to remedy a gross injustice and to give Raspail, who is incidentally the undisputed founder of the science of histochemistry, his due recognition as father of the cell theory.

DNA PROBES

(From the people who gave you Designer Genes™)

Human Interleukin 1∝

IL-1∝ is one of the two major forms of IL-1 identified. Probes are available for Exon 5, 6 and 7 of the IL-1∝ gene.

Human Interleukin 1ß

The other major form of IL-1. Probes are available for Exon 5, 6 and 7 of the interleukin 1ß gene.

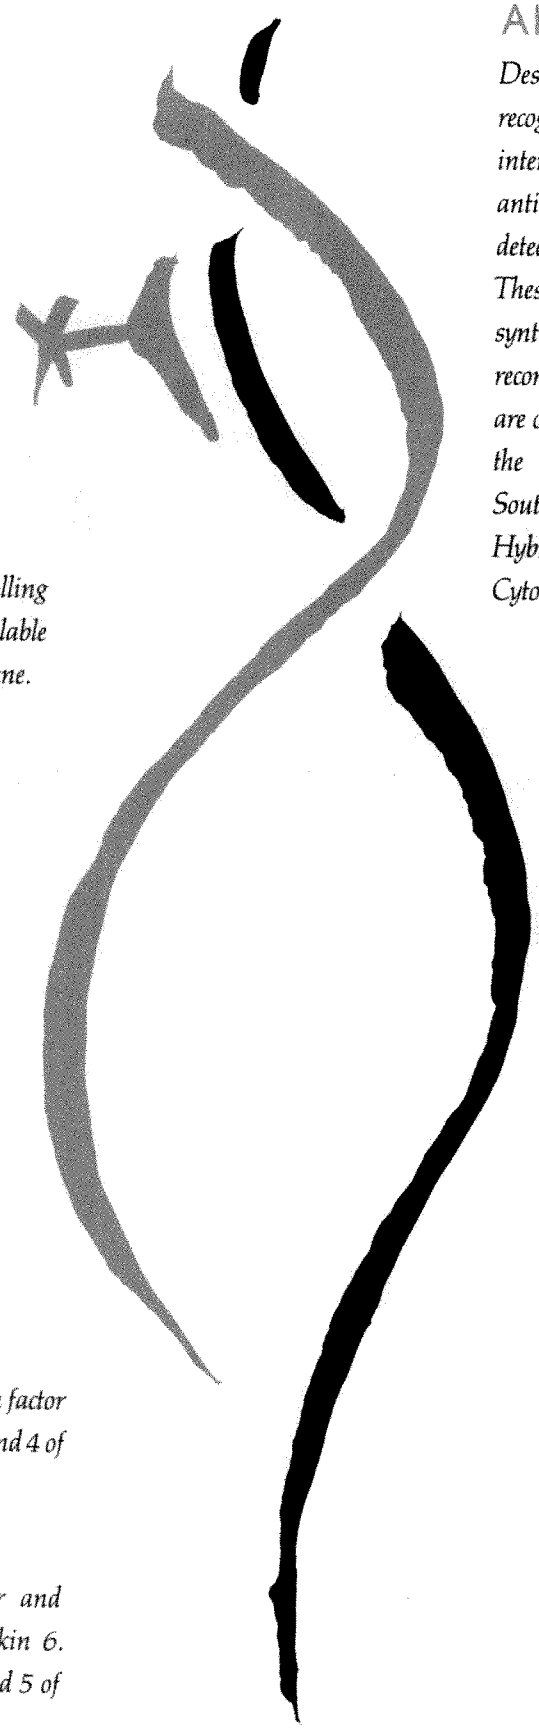
Human Interleukin 2

Interleukin 2 is a central factor controlling proliferation of T cells. Probes are available for Exon 1, 2, 3 and 4 of the IL-2 gene.

Human Interleukin 3

IL-3 is a growth and differentiation factor for multipotent erythroid and myeloid precursors. Probes are available for Exon 1, 2, 3 and 5 of the IL-3 gene.

Human Interleukin 4



With exon boundaries not yet fully defined for the IL-4 gene, probes have been designed for the 3′ region, mid-region and 5′ region of the IL-4 gene.

Human Interleukin 5

Interleukin 5 is identical to B cell growth factor II. Probes are available for Exon 1, 2, 3 and 4 of the IL-5 gene.

Human Interleukin 6

Interferonß$_2$, hybridoma growth factor and BSF-2 are now known to be interleukin 6. Probes are available for Exon 2, 3, 4 and 5 of the IL-6 gene.

APPLICATIONS

Designer Probes™ from British Bio-technology recognise certain unique exons of genes coding for interleukins. As the probes are based on the antisense sequence they are also suitable for detecting the corresponding regions in mRNA. These probes are single-stranded, chemically synthesized and supplied ready purified with recommended protocols for labelling. The probes are of defined length and Tm and are suitable for the following applications. •Northern and Southern Hybridisation •Colony & Plaque Hybridisation •In situ Hybridisation •Dot-blot & Cytodot Hybridisation.

PROBE COCKTAILS

Exon specific Designer Probes™ allow the identification of particular gene regions. The exons selected are all contained in the region coding for the mature forms of the proteins. Also available are Probe Cocktails which consist of an equimolar mixture of exon specific probes. Probe Cocktails will pick up a combination of different regions of the gene and therefore show a higher level of sensitivity than individual probes. Probe Cocktails can be used for all the applications listed above.

BIOTECHNOLOGY AND THE ENVIRONMENT: International Regulation

Jeffrey Gibbs, Iver Cooper, Bruce Mackler

Announcing the first comprehensive analysis of environmental regulation in biotechnology.

- **Reviews all aspects of U.S. regulatory policy**
  United States Environmental Protection Agency and biotech-related statutes – National Institute of Health Guidelines – United States Department of Agriculture's role – Food and Drug Administration – Coordination of federal regulation – National Environmental Policy Act – Endangered Species Act – Laws relating to transportation of products – Product liability suits brought by private citizens – Regulation by local governments
- **Describes the regulatory status of eleven industrialized countries in eleven different chapters**
  The United Kingdom – Australia – Austria – Canada – Denmark – the Federal Republic of Germany – France – Ireland – the Netherlands – New Zealand – Switzerland. Chapters were prepared by a contributing author from the subject country.
- **Analyzes international regulatory patterns and predicts future trends.**
  Environmental regulations in biotechnology have evolved dramatically. The authors examine the past patterns of this evolution, review current policies, and speculate as to what regulations may be in the future.
- **An invaluable source source for professionals in biotechnology, the law, and regulatory affairs**
  Biotechnology and the Environment is presented clearly and succinctly to benefit biotechnology and regulatory affairs professionals as well as lawyers and government regulators. The book places biotechnology in the context of general environmental regulation and describes how the present regulatory framework will accommodate biotechnology.
- **Three authors bring you their expertise as authorities on biotechnology regulation**
  Jeffrey Gibbs is Associate General Counsel for the Association of Biotechnology Companies and has written and lectured extensively on regulatory issues. Iver Cooper is the author of *Biotechnology and the Law*, and many articles on patent law. Dr. Bruce Mackler is general counsel to the Association of Biotechnology Companies. He specializes in microbiology and immunology, and is managing editor of the *Biotechnology Law Report*. All three authors are partners in the Washington, D.C. law firm of Mackler, Cooper and Gibbs.

THE EMBO JOURNAL

For the latest progress in molecular biology

Editor in chief
Max Birnstiel, *Chairman of EMBO Council*

Executive editor
John Tooze, *Executive Secretary of EMBO*

Editorial board
F Amaldi, *Italy*; D Baltimore, *USA*; P Berg, *USA*; K Beyreuther, *FRG*; G Blobel, USA; A Carafoli, *Switzerland*; F Cuzin, *France*; J Drenth, *The Netherlands*; A Fersht, *UK*; S Fuchs, *Israel*; D Gallwitz, *FRG*; B Hohn, *Switzerland*; D Hopwood, *UK*; T Jovin, *FRG*; W Keller, *FRG*; P Lawrence, *UK*; D Lilley, *UK*; D Louvard, *France*; J Meldolesi, *Italy*; M L Melli, *Italy*; D Meyer, *USA*; M van Montagu, *Belgium*; K Nasmyth, *UK*; D Nathans, *USA*; W Neupert, *FRG*; K Nordström, *Sweden*; S Numa, *Japan*; I Ohad, *Israel*; P A Peterson, *USA*; V Pirrotta, *USA*; R Planta, *The Netherlands*; R J Poljak, *France*; A Rich, *USA*; D Richter, *FRG*; J-D Rochaix, *Switzerland*; J Schlessinger, *USA*; J Seelig, *Switzerland*; F Stahl, *USA*; J A Steitz, *USA*; J P Thiery, *France*; J D Watson, *USA*; M Wikström, *Finland*; M Yaniv, *France*; R M Zinkernagel, *Switzerland*

Volume 8
13 issues in 1989
ISSN 0261-4189 Coden EMJODG

Full rate	US$435
Personal	US$135

EMBO member rate on application
Rates do not apply in Japan or UK: write for details

Back volumes: Complete set of volumes 1 – 7 is available at the discounted price of US$2436 – a saving of 20%.

Recent papers cover genetics, gene structure, replication and expression, cell biology, virology, macromolecular structure, molecular genetics, immunology, neurobiology, plant molecular biology and more. A year's subscription brings 13 issues – 2 in December – each with around 40 new, original papers. Every paper has to meet the standards of the EMBO editorial board, and the editors select only those papers of wide biological significance which merit fast publication. Generally, papers are published within four months of their receipt at the editorial office in Heidelberg; average time taken between their acceptance and appearance in the journal is *less* than 12 weeks.
The EMBO Journal is excellent value for money; over 4000 pages per year, yet individuals can still subscribe for only US$135 – including delivery by air.

ONLY US$135 FOR INDIVIDUALS

Authoritative science, fast publication, high-quality presentation – these are the hallmarks of *The EMBO Journal*, encompassing the broad range of the newest molecular biology.

Recent papers
The molecular basis of sulfonylurea herbicide resistance in tobacco *K Y Lee, J Townsend, J Tepperman, M Black, C F Chui, B Mazur, P Dunsmuir and J Bedbrook* ● Interaction of a nodule specific, *trans*-acting factor with distinct DNA elements in the soybean leghaemoglobin lbc_3 5′ upstream region *E Ø Jensen, K A Marcker, J Schell and F J de Bruijn* ● Selective suppression of human papillomavirus transcription in non-tumorigenic cells by 5-azacytidine *F Rösl, M Dürst and H Zur Hausen* ● Alzheimer's disease amyloidogenic glycoprotein: expression pattern in rat brain suggests a role in cell contact *B D Shivers, C Hilbich, G Multhaup, M Salbaum, K Beyreuther and P H Seeburg* ● DNA sequences outside the receptor-binding sites differentially modulate the responsiveness of the mouse mammary tumour virus promoter to various steroid hormones *A C B Cato, P Skroch, J Weinmann, P Butkeraitis and H Ponta* ● Processing at immunoglobulin polyadenylation sites in lymphoid cell extracts *A Virtanen and P A Sharp* ● Secretion of invertase in mitotic yeast cells *M Makarow* ● The mouse ribosomal gene terminator consists of three functionally separable sequence elements *A Kuhn, A Normann, I Bartsch and I Grummt* ● The *Escherichia coli* 30S ribosomal subunit; an optimized three-dimensional fit between the ribosomal proteins and the 16S RNA *D Schüler and R Brimacombe* ● Initiation of heteroduplex-loop repair by T4-encoded endonuclease VII *in vitro S Kleff and B Kemper* ● Three-dimensional structure of the regular surface glycoprotein layer of *Halobacterium valcanii* from the Dead Sea *M Kessel, I Wildhaber, S Cohen and W Baumeister*

How to choose the right Western blotting detection system.

- **Colloidal Gold**
- **Alkaline Phosphatase**
- **HRP**
- **Biotinylated probes**
- **Total protein stains**
- **Prestained standards**

Today there are many options available for detecting blotted proteins. Since each detection system has its own advantages and limitations, it's often difficult to make the right choice. To help you find your way through this maze of kits and reagents, Bio-Rad offers you in-depth assistance.

Free technical guide. This one-of-a-kind guide, titled "Western Blotting Detection Systems: How Do You Choose?", includes comparative information on sensitivity, specificity, stability, restrictions, and recommendations for blotting standards, total protein stains, and immunological detection systems. You'll find it a big help in choosing the best detection system for your application.

Blotting grade antibodies and reagents. Once you've made your choice, Bio-Rad supports you with a complete line of blotting grade reagents and kits. All of Bio-Rad's blotting grade antibody conjugates are affinity isolated and then further purified by affinity chromatography to eliminate interferences common to Western blotting experiments. All blotting grade reagents are quality tested in blotting experiments. Instructions provide thoroughly tested methods for performing immune detection assays.

Keeping you current. As Bio-Rad pioneers major innovations in Western blotting, we will keep you updated. For example, ask about our new **Protein G HRP** and **Protein G Gold** conjugates, and Prestained Standards. They offer superior results in many applications. Why not investigate?

Let Bio-Rad advise you of the best way to perform Western blotting. And provide the reagents and protocols to make sure you're successful on your first try. Contact Bio-Rad to get the free comprehensive blotting guide and more information on our complete line of Western blotting detection systems.

Ask About Our Latest Reagents for Western Blotting.

Answers.

European VLBI in limbo?

The failure of an important and worthy application for research funds to the European Commission demonstrates that Europe needs a more imaginative way of backing research that matters.

SOMETIMES, if rarely, there are research proposals that make perfect sense: the project is sound, indeed imaginative; the applicants have splendid track records, and are prepared to commit their own resources to the project; and there is every reason why the intended source of funds should welcome the proposal both as a vehicle for spending money wisely and because it furthers that organization's wider objectives. What executive officer of a grant-making organization could fail to jump at such a prize? Yet that is what the European Commission has just done.

The circumstances, which are not particularly complicated, concern the development of Very-Long-Baseline Interferometry (VLBI) in Europe. Everybody knows how valuable this technique has been shown to be in the past decade and a half. The principle is simply that of simultaneously pointing two or more radiotelescopes at the same distant radio source. The coordinated instruments then function as one instrument whose resolving power is proportional to the distances by which the instruments are separated (or, strictly, to the ratio of the baseline and the wavelength at which observations are made).

The principle is no different from that in which neighbouring radiotelescopes are deployed in concert to form a radiointerferometer, but there is a practical difference: because of the distances between the instruments, signals from different receivers cannot be compared in real time, but must instead be recorded on magnetic tape and correlated with each other later, using a device known as a correlator.

By now, the achievements of VLBI are widely appreciated. In the observation of distant radio galaxies, the technique promises the most direct observational evidence of what happens near the galaxy-sized nuclei of these often vastly extended objects, thus helping to decide whether the central galaxies are driven by black holes or by some other mechanism. Last year, an observation of the active nucleus of the radio galaxy 3C84 reported an accuracy of 100 microarcseconds (Bartel, N. *et al. Nature* **334**, 131; 1988), no doubt still a record. But there are many more familiar astrophysical processes, such as the mapping of star-forming clouds of gas and dust within our galaxy and the study of the movement of matter near peculiar binary stars, which have been made intelligible by the use of VLBI.

All this was expected at the outset. The surprise has been the usefulness of VLBI in geodesy and geophysics. Coordinated radiotelescopes can so accurately measure the orientation of distant radio sources relative to the Earth's surface that VLBI measurements have become standard measures of the motion of the Earth's poles (including the Chandler Wobble) and of variations in the length of the day.

The point has also been reached at which VLBI is yielding, in what might be called real time, a log of the relative movement of the Earth's tectonic plates. The uncertainty in baseline measurements, inferred from the observation of known distant objects, is already no more than 3 cm, comparable with the annual separation of the plates on either side of the Mid-Atlantic Ridge, and should be further reduced as more high-frequency instruments join the VLBI collaborations and as data analysis is improved. Already pairs of movable radiotelescopes have provided a plausible account of the internal distortion of the tectonic plate of the south-western United States.

But these developments are only a beginning. Coordinated observations by telescopes separated by the diameter of the Earth are commonplace, but now there are ambitions — even plans — to surmount the limitation of the Earth's finite size. The European and US space agencies have made a joint study of an orbiting radiotelescope, while there is a possibility that the Soviet Union may launch such a device in the early 1990s, as may Japan. VLBI, it seems, is booming.

That, sadly, is where recent European disappointments are ironical. From the outset, European radio-observatories have played an important part in wider international collaborations. Most of them now belong to a club, called the European VLBI consortium, which organises collaborations and worries about data acquisition and analysis.

There is the rub. For at least the past three years, it has been clear that existing facilities would soon be overwhelmed by data. Technically, there are two problems — that of recording data accurately in the expected volume (determined by the need to record with high time-resolution and over a range of frequencies) and that of comparing data from different stations so as to extract meaningful information.

This is what prompted the consortium last year to apply to the European Commission for funds with which to equip itself with suitable facilities. The hope had been that a correlator centre could be founded at the Westerbork observatory in the Netherlands, and that the Commission might also help equip individual stations with suitable recording equipment.

As might be expected, the Commission seems to have warmly applauded the proposal, as neat a marriage as there could be of scientific merit with the ideal of European collaboration. Much in the spirit in which censors about to ban books first read them through a second time, the Commission cannot be faulted for the attention which it has given the proposal. But the plan falls outside the terms of reference of the most relevant of the Community's research programmes, the Framework stimulation programme, which, administered by the CODEST committee, exists to bring European researchers together in research collaborations.

In grant-makers' terms, there are several pitfalls buried in the VLBI correlator project, not the least of which is that CODEST's own funds are repeatedly being overtaken by growing demands. But the VLBI correlator would also be a permanent institution, with annual running costs, of a kind that the Commission is not at present equipped (or even empowered) to shoulder. So everybody has been sympathetic, and CODEST has offered the consortium a grant of 300,000 ECU (which it should accept) to improve on its proposal, or even to commission the design of a data-recorder.

This is a sad state of affairs for which nobody is to blame — as yet. While member states delight in playing cat-and-mouse with the Commission over its science budget, it is natural that the Commission should shy from building institutions with implicit promises to support them. It is similarly natural that members of the consortium should obtain from national sources the equipment needed to remain in membership. And nobody can complain that the Commission should seek to make its funds go as far as possible by concentrating on "pump-priming seed-corn projects", to mix two grant-makers' metaphors.

But when, as on this occasion, it finds itself having to turn down a project of outstanding merit simply because its own rules are inappropriately designed, it should do the next most sensible thing — and change the rules.

John Maddox

NMR spectroscopy

Beyond the magic angle

J.M. Thomas

A RECENT technical achievement[1], which entails rapidly spinning a sample in a magnetic field around two axes at the same time, like a top within a top, promises to revolutionize the structural elucidation of solids by nuclear magnetic resonance. Double-rotation NMR is the term coined by the originators of this significant development, A. Pines (Lawrence–Berkeley Laboratory), E. Lippmaa and A. Samoson (Institute of Chemical Physics and Biophysics, Tallinn, Estonia). It should greatly extend the range of magnetic-resonance spectroscopy because it improves, by about two orders of magnitude, the accuracy with which the siting of certain types of atoms and ions in a solid may be distinguished.

NMR had humble beginnings, at least so far as those interested in the determination of molecular structure were concerned. Shortly after its invention in the mid-1940s, it seemed that NMR would be of premier concern to those whose ambitions were accurately to measure the fundamental properties of atomic nuclei. Then came the realization, greeted with growing excitement by chemists, that the precise frequency with which a given nucleus (of finite spin) resonates in an applied magnetic field is a delicate function of the local electronic environment of that nucleus. This gave birth to the notion of chemical shift. For example, protons (which are spherical, spin 1/2), resonate at frequencies governed by the chemical groupings to which they are attached: the resonating frequencies of –HCH–, –CH=CH$_2$, –C≡CH and –CO–OH are very different from one another. For other spherical nuclei the range of chemical shifts is large; and ^{13}C NMR readily distinguishes between aliphatic and aromatic carbons, just as ^{29}Si spectra discriminate between the 4- and 6-coordinated element. This is one of the main reasons why NMR is an indispensible structure-determining tool in the physical and biological sciences.

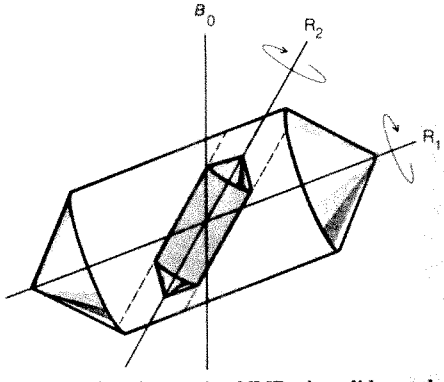

Fig. 1 In double-rotation NMR, the solid sample is rotated at an angle to the axis of the holder which is itself spun at an angle, the magic angle (54.74°), to the applied field B_0. The angle between R_1 and R_2 is 30.56°. Together these rotations remove dipolar and quadrupolar line broadening. (From ref. 1.)

In NMR spectroscopy one measures, *inter alia*, the radio frequencies emitted by, and the rates of realignment of, nuclear spins in a magnetic field after they absorb energy from radio-wave pulses. Because of random motion executed by entities in the fluid state, anisotropic magnetic and electrical interactions are averaged out so that high-resolution spectra may be routinely obtained with liquids and solutions. With solid samples there is no such averaging and the NMR spectra are hugely broadened. For a long time the prospects of retrieving chemical shift information from solid-state NMR spectra looked bleak until, in 1958, Andrew *et al.*[2], at the University College of North Wales, and Lowe[3] realized that the blurring effects of spectral resonances are represented mathematically by a term that contains the factor $(1-3\cos^2\theta)$. By spinning the sample about an axis at an angle $\theta = 54.74°$ (equals $\cos^{-1} 1/\sqrt{3}$) to the magnetic field, the solid behaved as if it were an isotropic liquid, and high-resolution spectra of a quality comparable to those achievable with liquids could be obtained.

Although magic-angle-spinning (MAS) NMR has been of enormous value in recent years in the study of solids[4,5] in general, and of absorbents and catalysts[6] in particular, as well as of a wide range of quasicrystalline and membranous materials — for which competing techniques such as X-ray crystallography are not as well suited — it has hitherto suffered from one rather serious limitation: quadrupolar nuclei (non-spherical ones, with spin greater than 1/2, like ^{11}B, ^{17}O, ^{23}Na and ^{27}Al), which are more numerous than spin-1/2 nuclei, give rise to broadening influences that are not eliminated by spinning at the magic angle of 54.74° nor by resorting to other strategies such as radio frequency manipulation of the spins.

This has meant that many problems of great interest to the solid-state chemist and physicist and to the materials and earth scientist have remained beyond the reach of high-resolution solid-state NMR. One practical, though costly, way of minimizing this limitation is to employ ever-higher magnetic fields, as second-order quadrupolar broadening effects are inversely proportional to the field strength. This approach has indeed been successful[7] in the study of zeolites, for which ^{27}Al MAS NMR spectra recorded at 11.744 tesla, but not at lower (7.946 or 9.359 tesla) fields, resolve two crystallographically distinct tetrahedral framework sites.

But double-rotation NMR offers an alternative route forward. By employing two 'magic angles' — the customary one of 54.74° and a new one of 30.56°, appropriate for the quadrupolar nuclei — essentially all the blurring effects that broaden the resonances are eliminated as a result of the complex motion to which the sample is subjected (Figs 1 and 2). The powdered solid rotates inside a holder which simultaneously rotates on a second axis, air jets and air bearings being used to achieve rotation speeds of up to 6 kilohertz.

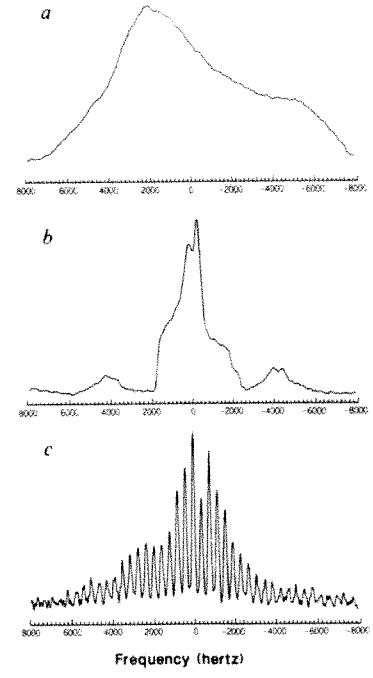

Fig. 2 The NMR spectrum of ^{23}Na in polycrystalline sodium oxalate, from a static sample (*a*), a magic-angle-spinning experiment (*b*) and a double-rotation experiment (*c*). The linewidth is reduced from 12,000 to 4,000 to 140 hertz, respectively, as dipolar and quadrupolar broadening are suppressed. The sidebands in *b* and apparent 'structure' in *c* are related to the spinning frequencies. (From ref. 1.)

The Berkeley–Tallinn team has already demonstrated that the technique works for ^{23}Na nuclei, two well-resolved signals (of width 75 hertz) being obtained from a mixture of the sulphate and oxalate of sodium. With the very recent report (A. Pines *et al.*, preprint) that the mineral diopside (isotopically enriched) yields three distinct ^{17}O signals, the stage is now set for exciting developments in the elucidation of structures and mechanisms of interest to the earth scientists, materials engineers and those investigating catalysts, adsorbents and warm superconductors. There is a paucity of techniques capable of probing directly the precise electronic nature of oxygen ions in such solids

Electron-energy-loss spectroscopy (oxygen K-edge structure), X-ray spectroscopy and electron spin resonance are rather specialized though quite useful tools. But ^{17}O double-rotation NMR is potentially more powerful.

For zeolite-rho, faujasite (zeolites X and Y) and ferrierite, all of which are important solid catalysts, there are known to be, respectively, two, four and eight crystallographically distinct oxygen sites. Will these be resolved by double-rotation NMR (like the 24 silicon sites[8] in the ^{29}Si MAS NMR spectrum of ZSM-5)? And will there be only one peak in the ^{17}O double-rotation NMR spectrum of sodalite? Or more, if there are Al–O–Al linkages[9] present? These answers will determine the new directions which solid-state NMR will give to the structural elucidation of new zeolitic and related catalysts. Likewise, with ^{17}O enriched superconducting ceramics, apart from identifying crystallographically distinct oxygens, one may hope to find direct evidence for the so-called charge-disproportionation mechanism ($O^{2-} + O^0 \rightarrow 2O^-$) or the existence of the previously postulated peroxy, ionic species, O_2^{2-}. These issues need to be clarified if we are to understand the transport mechanisms in the various families of oxide superconductors. □

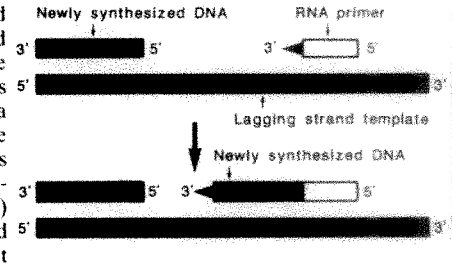
Telomerase

The beginning of the ends

Jack W. Szostak

EVERY time a linear chromosome is replicated it is in danger of being whittled away from both ends. The origin of this danger lies in the requirement of DNA polymerases not only for a template to copy but also a primer to extend: because polynucleotide synthesis can proceed in only one direction, from 5′ to 3′, this leads to a problem in copying the 3′ ends of both strands of a linear chromosome, where there can be no primer to extend (see figure). A common solution to this problem is to have simple repeat sequences at the telomeres (ends) of linear chromosomes, and a specialized system for generating additional repeats, compensating for loss in replication. Greider and Blackburn isolated and characterized[1,2] an enzyme that can synthesize telomeric repeats; notably, this telomere terminal transferase has an essential RNA component. The same authors, on page 331 of this issue[3], find that the RNA component of the telomere terminal transferase of *Tetrahymena* contains the complementary sequence of the telomeric repeats that it synthesizes, strongly suggesting that the enzyme is a remarkable kind of DNA polymerase that carries its own template.



The existence of telomerase was originally hypothesized[4] to explain several bizarre properties of telomeres. Synthesis of new telomeric repeats has been observed in three very different organisms. In *Tetrahymena* and other ciliates, chromosomes are fragmented and new telomeres are formed spontaneously during the formation of macronuclei. In yeast, linear plasmids made *in vitro* with *Tetrahymena* telomeres can be elongated *in vivo* with newly synthesized yeast telomeres. And in trypanosomes, telomeres elongate steadily at about one repeat per generation during somatic growth. Of course, telomerase also provides a ready explanation for the maintenance of normal telomere length in the face of incomplete replication.

The *Tetrahymena* telomerase is a ribonucleoprotein that adds GGGGTT repeats to short, single-stranded, synthetic oligonucleotides. Only telomere-like sequences are elongated; random-sequence oligonucleotides are ignored by the enzyme. How is this specificity obtained? Greider and Blackburn[1–3] cloned and sequenced the RNA component of telomerase, and find embedded within it the sequence CAACCCCAA — one and a half repeats of the complement to the synthesized sequence. Furthermore, they show that the enzyme can be inhibited by oligonucleotides complementary to this sequence, and inactivated by RNaseH cleavage at this site. Even more remarkably, an oligonucleotide that lines up just 5′ to this sequence, but contains no telomeric repeats itself, can be elongated by the enzyme, further implicating the RNA as a template[3]. No doubt we shall soon see the sequences of corresponding RNAs from related organisms with different telomeric repeats; if the RNA does indeed act as a template, each one should contain the appropriate complementary sequences. An even more decisive experiment would be possible if such an RNA template could be found in yeast: replacement of the resident gene with one modified to change the template sequence should generate yeast with any desired telomere sequence.

But do all eukaryotes replicate their telomeres with the aid of telomere terminal transferase? Similar enzymes have been detected in other ciliates — *Oxytricha*[5] and *Euplotes* (Shipper-Lentz, D. & Blackburn, E.H., submitted) — so the role of this enzyme in these organisms seems assured. But it has not yet been detected in yeast, despite several attempts to find it. This is not necessarily surprising — the ratio of telomeres to total genomic DNA is about 1,000-fold less in yeast than in ciliates, so there may simply be very little of the enzyme in yeast. Still, most eukaryotes never need to generate telomeres *de novo*, and might perhaps be able to use some sort of recombinational process to elongate them. In such models, a telomeric 3′ end could invade at an internal site in another telomere, where it could be elongated by polymerase on the existing template. Such a gene conversion-like process could lead to the same elongation as is achieved by telomere terminal transferase. Indeed, recombination is almost certainly responsible for maintaining the average telomere length of *Tetrahymena* mitochondrial DNA[6].

Does recombination actually play a role in telomere elongation in yeast? Pluta and Zakian[7] have done a cleverly designed experiment in which they prepared hybrid linear DNA molecules with CCCCAAAA repeats at one end and CCCCAA repeats at the other. After transformation into yeast, each end is elongated with yeast $C_{1-3}A$ sequences, as expected. Hybridization analysis of the resulting linear plasmids reveals that in many cases CCCCAAAA sequences have been transferred to the CCCCAA end, and vice versa.

How has this happened? Pluta and Zakian suggest that recombination between the ends has taken place and,

Eukaryotic DNA replication. Each new strand of DNA is synthesized on a template provided by one of the old strands (only one strand, the lagging strand, is shown here). But synthesis can be initiated only in the presence of a primer, which is provided by a 10-nucleotide RNA primer synthesized about 200 nucleotides 3′ to the replication fork. DNA is thus synthesized in short fragments (Okazaki fragments) from 5′ to 3′, the RNA primers being degraded and replaced with DNA as each fragment reaches the one preceding it. The 3′ ends of the DNA strands cannot be replicated in this way, however, because there is no more DNA left on which to synthesize the RNA primer.

furthermore, that similar recombination events involving yeast telomeres could be responsible for the subsequent addition of the $C_{1-3}A$ repeats, and for telomere elongation in general. Because their observed events are independent of the *rad 52* gene product, which is required for all other known recombination events involving double-stranded ends, some new, perhaps telomere-specific, system could be involved, if indeed recombination is responsible for these events.

Work from my laboratory argues against an essential role for recombination in telomere elongation[8]. We were surprised to find that 20–60 base pairs of non-telomere DNA can commonly be retained in between CCCCAA repeats present on the input DNA and the $C_{1-3}A$ DNA added on in yeast. Because these linker sequences are unrelated to telomeric repeats, the subsequent addition of $C_{1-3}A$ repeats cannot involve homologous recombination.

Our results also provide an alternative explanation for the results of Pluta and Zakian[7]. A resolution reaction that can separate ligated telomeres is well-documented in yeast[9]. If the two different telomeres became ligated in yeast, and then resolved by breakage within one of the stretches of telomeric repeats, the observed movement of DNA would take place. Pluta and Zakian reject this explanation because the transferred segment would be inverted relative to the normal telomeric orientation. Telomeric sequences in the wrong orientation are known not to be elongated in yeast. In the light of our results[8], however, it is likely that a short stretch of inverted telomere DNA would not block subsequent elongation. The only way to resolve this point is to clone and sequence several examples of the chimaeric telomeres to determine the orientation of the transferred segment. □

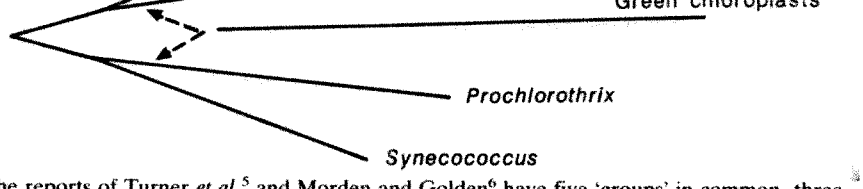
Molecular evolution

What, if anything, is *Prochloron*?

David Penny

IT is almost 20 years since the suggestion[1] that free-living photosynthetic prokaryotic organisms containing chlorophylls *a* and *b*, but lacking phycobilin pigments, existed a billion years ago. These hypothetical organisms would be ancestors of the chloroplasts of green plants. At that time, the notion seemed reasonable, but scarcely testable. I still remember the excitement five years later when a possible member of such a group was found alive and well, living in Baja California, Mexico[2]. The organism was named *Prochloron*, and the group prochlorophytes. But the first work[3] comparing fragments of nucleotide sequences from ribosomal RNA of these organisms did not support prochlorophytes being the ancestor of green chloroplasts. Rather, it seemed that chlorophyll *b* had developed separately in *Prochloron* and chloroplasts. Progress in clarifying the position of *Prochloron* has been slow because it cannot be grown in culture. Recently, a free-living form *Prochlorothrix*, a presumed relative of *Prochloron*, has been discovered and cultured[4]. On pages 380 and 382 of this issue[5,6], two groups report on the evolutionary position of *Prochlorothrix* but reach apparently conflicting conclusions.



Turner *et al.*[5] compare the nucleotide sequences of the small-subunit (16S) RNA from *Prochlorothrix*, chloroplasts and cyanobacteria. They use distance methods for building evolutionary trees and estimate the accuracy of their results by 'bootstrapping'. Their trees clearly separate green chloroplasts from *Prochlorothrix*, in agreement with the earlier results[3]. In this scheme, the closest relative of a chloroplast ancestor would be the 'chloroplast' (cyanelle) of the protist *Cyanophora*, which has typical cyanobacterial structure and biochemistry. The interpretation is that the loss of phycobilins, and the gain of chlorophyll *b* has occurred at least twice.

Morden and Golden[6], on the other hand, use DNA sequences from a photosynthetic membrane protein (*psbA*) from photosystem II. They use the position of deletions in the molecule as well as trees built using the parsimony (minimum mutations) criterion and come to the opposite conclusion, namely that the prochlorophytes such as *Prochlorothrix* are the ancestors of the green chloroplasts. Similarities and differences between the reports[5,6] are shown in the figure.

Such an impasse demands comment. First, neither group supports the idea[7] that prochlorophytes are a very ancient group that evolved at the same time as cyanobacteria. It is small consolation that at least the two sequences put *Prochlorothrix* into the same main taxonomic group. Putting aside for the present special pleading such as lateral transfer, can we predict which conclusion will eventually be proved correct? Unfortunately, no.

Two strengths of the method of Turner *et al.*[5] are bootstrapping to give an estimate of errors and a correction for unequal rates of change on different nucleotides. But the method could be sensitive to unequal rates on different lineages[8]. Turner *et al.* have two sets of biochemical data, RNA sequence and photosynthetic pigments (including information on biosynthetic pathways and chlorophyll-binding proteins). If the two sets of data do agree then it is valid to say they support the same tree. If they do not then it is difficult to justify ignoring completely one or the other. The authors appear to assume their RNA tree is correct and give a zero weighting to the pigment data.

Another possible difficulty is that there could be some convergence of function in 16S RNA sequences in chloroplasts. This could lead to the *Cyanophora* and chloroplast sequences converging sufficiently to come together on the tree. An example of functional convergence has been found with lysozyme in two groups of mammals

The reports of Turner *et al.*[5] and Morden and Golden[6] have five 'groups' in common, three standard cyanobacteria, *Prochlorothrix* and chloroplasts from green plants. Assuming the differences in isolates are unimportant, the first four give the same rooted tree for 16S RNA and the *psbA* gene. Thus the difference is not in the position of *Prochlorothrix* but rather in the green chloroplasts. The 16S-RNA results[5] derive the chloroplasts from near *Synecococcus*, which requires chlorophyll *b* to have arisen twice as a photosynthetic pigment. The *psbA* results[6] derive chloroplasts from 'prochlorophytes', thus giving a single origin of chlorophyll *b*.

with ruminant digestion, ungulates (including cattle) and Langur monkeys[9]. If convergence has occurred, then one test is to run the RNA data without *Cyanophora*. *Prochlorothrix* should now join with chloroplasts. But there is other evidence[10], observations of the ultrastructure, for example, that could relate the *Cyanophora* group to the green plants and support the tree of Turner *et al.*. It would also be interesting to determine the sequence of some anomalous protists that have chlorophyll *b*, such as *Chlorarachnion*[11].

Morden and Golden[6] find that the two types of biochemical data do agree, but apart from omitting nucleotides in the region of the deletion, they do not test the accuracy of their tree. Parsimony methods are susceptible to error from long edges coming together[8]. Sequences from chloroplasts of the ancient green algal group Prasinophyceae may be particularly helpful in resolving this question. In addition, Morden and Golden[6] report a smaller selection of cyanobacterial sequences (7 sequences from 5 taxa compared with 17 RNA sequences). It is still possible that additional *psbA* sequences from cyanobacteria would fall between green chloroplasts and *Prochlorothrix* and thus separate these two groups. It is therefore important to determine more sequences, including the *Cyanophora* cyanelle.

How can the impasse be resolved? I have made suggestions for additional sequences (or temporarily deleting sequences). It is always safer to reconstruct trees by more than one method, wherever possible using more than a single molecule. One method with one coding sequence seems insufficient to reconstruct unambiguously the whole of evolution. Methods such as convergence, bootstrapping and jackknifing[12,13] are available to help estimate accuracy.

Where, then, do we stand? The biggest difficulty is in persuading people that collecting sequences is the easy part of any study. The hard part is estimating the accuracy of the results. In some areas of molecular biology it is accepted that, for example, establishing secondary and tertiary structure from sequences is much harder than obtaining the primary sequences. Any measurement, to be scientific, must include an indication of its accuracy. Despite the progress that has been made, reconstruction of evolutionary trees from sequence data must still appear to those in other fields as parascientific. □

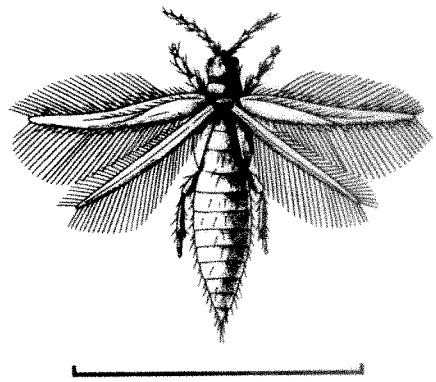
Evolutionary ecology



Diversity of little things

Jon Seger

We are gigantic animals. If there are 10 million species (probably a conservative estimate[1,2]), then we are among the largest 0.001 per cent. Songbirds, mice and honeybees seem small to us, but they are almost certainly in the top 1 per cent. The remaining 99 per cent consists mainly of insects and mites with average body lengths of roughly 3 mm[2,3] (the size at which we cease to notice things even when they land in our soup). An immense diversity of life-histories and reproductive biologies would be expected to occur at these sub-sub-lilliputian scales, simply because there are so many species. In fact, the action appears to be disproportionately concentrated among very small animals. To cite just one of many possible examples, parthenogenesis in its many varieties is overwhelmingly most common among small arthropods[4,5]. The report by Crespi on page 357 of this issue[6] describes what is apparently the first known instance of facultative viviparity, in which individual females can lay eggs, or give birth to live young, or both. This feat is performed by a 5-mm thrips.

Thrips (see figure) belong to the insect order Thysanoptera ('fringed wings'). Most species are small to very small (5–0.5 mm), and most live on plants. The order is thought to be primitively haplodiploid, in the style of Hymenoptera, with haploid males arising from unfertilized eggs (arrhenotoky) and diploid females arising from fertilized eggs. Completely asexual reproduction is known in some species, but most seem to be fully sexual (on the female side). Most species lay eggs, but some are wholly or partially viviparous.

In the species studied by Crespi (*Elaphrothrips tuberculatus*), reproductive mode is associated with sex of offspring: male offspring are produced viviparously and female offspring oviparously. During a given bout of reproduction, a female is

A typical thrips from the order Thysanoptera. Scale bar, 1 mm.

either viviparous or oviparous. But by placing females in fine-mesh bags, under otherwise natural conditions, Crespi demonstrates that many long-lived females switch modes, thereby producing offspring of both sexes.

Because sex of offspring is associated with reproductive mode, and the sex ratio is subject to powerful frequency-dependent selection, roughly equal numbers of females should be found in each mode at any given time. Crespi's study population has two generations per year. In the summer generation there is a slight excess of male-producing, viviparous females, but in the spring there is a large (3:1) excess of female-producing, oviparous females[6–8]. If this pattern of sex allocation represents an evolutionary equilibrium, then the population probably experiences local mate competition[9] (differential migration of the sexes) or partial bivoltinism[10,11] (differential survival of the sexes between generations), or both.

Adult males guard gravid oviparous females for hours or days at a time, but they usually ignore viviparous females[7]. This behaviour is consistent with the assumption that *E. tuberculatus* is haplodiploid, because male offspring have no fathers under haplodiploidy.

Viviparous females have only about half the fecundity of oviparous females, but newly laid eggs suffer considerable mortality before hatching. In the end, each reproductive mode yields roughly the same number of pupal offspring. Why, then, should male offspring be produced viviparously? One obvious adaptive hypothesis is that males benefit more than do females from entering the world in an advanced state of development. Crespi has previously shown[7] that because success at mate-guarding is strongly size-dependent, males benefit more from being relatively large than do females.

But if being produced viviparously is good for males, surely it should be good for females as well. Why, then, are female offspring not produced in the same way? A plausible nonadaptive hypothesis is simply that the evolutionary transition to viviparity is easier under parthenogenesis than it is under sexual reproduction,

perhaps because the egg must be fully ovulated before it can be fertilized. Within the arthropods as a whole there seems to be a strong association between viviparity and parthenogenesis (N.A. Moran, personal communication); this pattern is particularly striking in cyclical parthenogens such as aphids and *Daphnia*. Even so, some taxa manage to combine viviparity and sexual reproduction (for example, parasitoid flies that 'larviposit' on their hosts). It will be interesting to see what turns up in thrips as more species are studied in detail.

Large animals easily excite our emotions; small ones probably would if we knew them better. They make up most of the Earth's biotic diversity, in several senses of the word, and they remain largely unnamed and unstudied. This means that many thousands, even millions, of small species may be driven to extinction through habitat destruction[12] before we even note their existence. But millions more are likely to remain, still the richest part of "life on a little-known planet"[13]. □

Oxide superconductors

Electron doping tests theories

V. J. Emery

THE discovery of electron superconductivity in cuprate compounds, reported by Tokura *et al.* on page 345 of this issue[1] has significant implications for our understanding of high-temperature superconductors. The charge carriers in previously known cuprate superconductors can be thought of as holes, or missing electrons. Typically an insulating material is rendered metallic by substituting divalent ions for trivalent ones (say, Sr^{2+} for La^{3+}) or by adding oxygen, which enters the compound as O^{2-}: to maintain charge balance, electrons are removed from the (superconducting) copper oxide planes. Tokura *et al.* went in the opposite direction. Starting from Ln_2CuO_4, where Ln is one of the lanthanides Pr, Nd, or Sm, they replaced Ln^{3+} by Ce^{4+} and removed oxygen by annealing under reducing conditions. In this way electrons are added to the CuO_2 planes, and superconductivity is achieved when the carrier concentration exceeds about 20 per cent per formula unit.

At this early stage, rather little is known about the electronic and magnetic properties of the new materials produced by Tokura *et al.*, although they surely will be studied closely during the next few months. But because the supercurrent is carried by electrons rather than holes and because of the planar copper coordination (see below), the new materials allow new kinds of tests of theories of high temperature superconductivity.

The simplest possibility is that the CuO_2 planes in the insulating parent compounds, Ln_2CuO_4 and La_2CuO_4 turn out to be particle–hole symmetric, that is they behave in the same way if electrons are added or removed. Indeed this is a property of 'single-band' models[2–4] of the CuO_2 planes, which neglect all the electron states in the material (or energy bands) apart from a partially occupied band bearing the delocalized charge carriers. In some ways this would be the least interesting, but nonetheless important, outcome, replicating properties already observed in existing materials.

An alternative point of view[5] is that the Coulomb interactions between the charge carriers are so strong that other bands cannot be ignored. In the parent compounds the O($2p$) levels are filled and the holes are in Cu($3d$) states, giving Cu^{2+} ions with a spin that is responsible for the observed magnetic behaviour. When holes are added by doping they go into ($2p$) orbitals because the strong Coulomb repulsion makes Cu^{3+} extremely unfavourable energetically. Because the O($2p$) orbitals become partially filled, the added holes can form a conduction band which ultimately leads to superconductivity. Of course the situation is not so extreme, there is some hybridization (mixing of states), but to talk of localized moments on copper and mobile holes on oxygen is a convenient 'zeroth order' way of speaking.

There is much evidence[6,7] in favour of this picture mainly from X-ray, electron and ultraviolet spectroscopy as well as from neutron-scattering experiments. Indeed, the outstanding issue is not so much whether the holes are on oxygen but rather which of the possible $2p$ states are populated. Electron doping would give a different result, however, because the O($2p$) level is filled in the parent compound, and the electrons must go onto copper sites to produce Cu^+. This conclusion could be verified by X-ray absorption near-edge spectroscopy[6] for example. It is clear that the T' structure of the new materials[1] (in which each copper ion sits in a square plane of oxygen ions) is electrostatically favourable for electron doping onto copper: unlike other structures there are no apical O^{2-} ions sitting directly above or below the copper sites repelling the excess charge.

Naively, the closed-shell Cu^+ ions behave like vacancies (missing spins) in the array of local Cu^{2+} moments which are magnetically coupled with a strength J. The vacancies are mobile because an electron can hop with amplitude t from Cu^+ onto a neighbouring Cu^{2+}. This is formally identical to the so-called t–J model[8] which may be derived from the single-band model[2–4] in the limit of strong interactions, and has been widely used to study magnetic mechanisms of superconductivity. In this way, the simplest versions of the two models might coincide for electron doping. At the same time, there is an ongoing debate about whether, for some purposes, the same may be true for hole doping. Specifically, for low-energy properties, such as magnetism, the mechanism of superconductivity and parameters of the superconducting state, does a hole on oxygen behave in the same way as a missing spin[9,10]? If so, there would be a limited and more elaborate form of particle–hole symmetry. The new materials may shed some experimental light on this important question.

A study of magnetic properties will be particularly interesting in this regard. It is already known from neutron-scattering experiments by Torardi *et al.* (D.E. Cox, personal communication) on Pr_2CuO_4 and muon-spin-rotation ones by Luke *et al.* (Y. Uemura, personal communication) on Pr_2CuO_4, Nd_2CuO_4 and Sm_2CuO_4 that the end members have magnetic order. For Pr_2CuO_4, the ordering temperature is about 260 K and the magnetic structure is similar to that of La_2CuO_4, with an ordered moment of about 0.5 Bohr magnetons per copper atom (Cox). An extension of these studies to the doped materials will enable us to contrast the effects of holes on oxygen and electrons on copper

as the magnetic order gives way to superconductivity.

Of course this naive description of electron doping is not the whole story. A Cu^+ ion will polarize its environment, giving rise to some density of holes on the surrounding oxygen sites. Just as for hole doping, the charge carriers are complex and extended entities and there are more routes to superconductivity than the simple *t–J* model allows. Many proposed mechanisms will require rethinking. Those relying on a displacement of the position or the charge of apical oxygens or the associated splitting of the Cu(3*d*) levels are clearly ruled out. Others emphasizing charge transfer between copper and oxygen must adapt to the new location of the charge carriers. □

Astronomy

Mass loss from Wolf–Rayet stars

Roger J. Tayler

WOLF–RAYET stars are very massive stars which are undergoing very rapid mass loss, typically several times 10^{-5} solar masses ($M_\odot$) per year[1]. Although most investigators believe that the mass loss is primarily driven by the pressure of the star's radiation, the momentum being communicated to the flow by very strong absorption in selected spectral lines, there is not complete agreement on this point. In a recent paper, Moffat *et al.*[2] report observations of five Wolf–Rayet stars in which the mass loss has an irregular blob-like structure and they believe that this property might help to distinguish between various proposed mass-loss mechanisms.

It has become clear during the past 20 years that a very wide variety of stars experience mass loss at rates ranging from the solar wind of a few times $10^{-14}\ M_\odot\ yr^{-1}$, or less, to the dramatic loss of many $M_\odot$ in the explosion of a supernova. In most cases the mass loss becomes apparent through the existence of very broad emission spectral lines which can be understood only in terms of mass leaving the star; in some cases direct observations are ambiguous as regards infall or outflow but there are usually other features which resolve the ambiguity. The most simple theoretical discussion of mass loss assumes that it is steady and spherically symmetric and such a discussion gives a first qualitative understanding of what is happening. It is, however, by no means certain that mass loss has this property.

For example, if the star is rapidly rotating or possesses a significant magnetic field, it will not be spherical and it is therefore unlikely that any mass loss will have spherical symmetry. If the mass loss is initiated by pulsation of the star, there will be time variations. Finally, a spherically symmetrical outflow might be thermally unstable, leading to the formation of cool dense blobs in a hotter diffuse flow. Evidence for such departures from the simple model can be found by studying the detailed profiles of the spectral lines which provide evidence of mass loss.

In the case of stars with low surface temperatures such as the Sun, the mass loss is strongly influenced by, if not determined by, the structure of the magnetic field at and above the star's surface. The field is maintained by a dynamo process in the star's outer convection zone and its strength seems to depend on the rotation speed of the star. The field structure is complex with some magnetic field lines forming closed magnetic loops within a few stellar radii and with others extending to large distances from the star. It is not surprising that in this case the mass loss is not spherically symmetrical. It is concentrated along the open field lines, while the energy input at the base of the closed loops raises the confined gas to much higher temperatures. Interestingly, in the case of one cool star, AB Doradus, Robinson and Collier-Cameron[3] have shown that the gas confined by the loops has apparently suffered thermal instability so that cool clumps of matter are embedded in the hot gas.

Moffat *et al.*[2] now show, by a study of emission lines of helium in five hot Wolf–Rayet stars, that their mass outflow must contain blobs of material. What they have observed are bumps in the spectral line profiles, which have the property that those starting redshifted relative to the line centre become more redshifted with time, while those starting blueshifted become more blueshifted with time. Their conclusion is that they are seeing blobs of material which are being accelerated outward, some on the near side of the star and some on the far side. Their study of the time of appearance of the blobs indicates that they cannot be related to any fully predictable property of the star, such as rotation or magnetic field structure or a regular pulsation. The blobs appear to arise randomly in starting time and in direction outward in the flow and this can probably be understood in terms of a stochastic instability of a radiatively driven wind as was proposed by Rybicki[4].

In his discussion, Rybicki[4] developed work by other authors on various possible instabilities in outflowing winds. The sensitive velocity dependence of radiative driving due to absorption in a spectral line is a particularly important source of instability. An element of material moving faster than neighbouring elements Doppler shifts the spectral line to a wavelength which has not yet suffered absorption and this leads to stronger driving and instability. Because of the outward motion such instabilities are rapidly advected away and they cannot form a coherent pattern around the star. This appears to accord with the observations of Moffat *et al.*[2], although further work will be needed to determine whether quantitative agreement between theory and observation exists. □

Agricultural genetics

Moving in on plant genes

Robert Shields

VIRTUALLY nothing is known about the protein products of the genes controlling morphology, dormancy, photoperiodicity and disease resistance in plants. Two techniques being used to try to clone these genes are transposon tagging and gene mapping. Transposons (mobile pieces of DNA) can generate different phenotypes which should allow the genes governing the phenotype to be isolated; and mapping should allow specific genes to be targeted. Although tagging is the more elegant technique, a new report[1] by Young *et al.* indicates that mapping may be the first method by which one of these genes is uncovered.

Transposons can be used as simultaneous mutagens and gene tags. Several plant genes (mainly those involved in pigment biosynthesis) have been cloned in this way from maize or snapdragon. The discovery[2] that the transposon Ac in maize could be transferred to other plants, where it is moved from its original site of insertion to a new locus, was therefore met with considerable excitement. Self-fertilization of the resulting plant will give the tagged locus in a homozygous state and simultaneously reveal a new phenotype. But things may not be that straightforward. In its native host, Ac tends to excise and then reinsert at a closely linked site on the same chromosome[3]. If this is true in the heterologous host, it will be necessary to produce plant lines with transposons inserted close to target genes before tagging can begin. In other organisms such as the fruitfly *Drosophila*, where transposons act as mutagens, specific loci are mutated at vastly different rates as the elements show strong site-specificity for insertion[4]. So, although it may be possible to isolate plant genes by transposon tagging, there may be problems in approaching specific loci by this method.

In several plant species, genes have been assigned to positions in genetic linkage groups which in a few plants can be correlated with cytologically identifiable chromosomes. The resolution of many of these linkage maps is poor and several laboratories are attempting to improve them by constructing maps based on restriction fragment length polymorphisms (RFLPs). These maps have a use as a practical breeding aid, for if an RFLP marker shows close linkage with a desirable gene then progeny in breeding experiments can be rapidly screened for its presence without the necessity for large-scale field trials. A secondary use of such maps is to use them as starting points for attempts to isolate the linked gene.

The first requirement is to position the target gene accurately on the RFLP linkage map and if necessary find new RFLPs which map closer to the gene. Young *et al.* have now elegantly demonstrated[1] the combined use of RFLPs and near-isogenic lines to find markers very close to a plant disease-resistance gene. Plant breeders often cross a cultivated variety with an alien species carrying a desired gene and then backcross to the cultivated variety (the recurrent parent) while selecting to maintain the required trait. After a series of such crosses, the genome of the selected plants will consist almost entirely of the genome of the recurrent parent with a small segment surrounding the target gene which comes from the alien genome. By examining RFLP differences between the original variety and the new near-isogenic line, it is possible to identify RFLP markers lying very close to the introgressed gene. Young *et al.* find markers lying 0.4 ± 0.4 centimorgans (= 2 × 10^5 base pairs in tomato) of the *Tm2a* gene (a dominant gene giving resistance to tobacco mosaic virus by restricting cell-to-cell spread) which had been introgressed into the cultivated tomato (*Lycopersicon esculentum*) from the wild variety *L. peruvianum*. Near-isogenic lines should be extremely valuable for rapidly assigning introgressed genes to their map position.

The correlation between the genetic and the RFLP map is limited by the frequency of allelic variation in the organism examined (which determines the likelihood of finding RFLPs) and the number of cases that can be examined where the target gene and closely linked RFLPs are segregating (which gives the map position). In practical terms 1 centimorgan (1 per cent recombination) is close to the limit of resolution achievable without examining a prohibitively large number of crosses unless near-isogenic lines can be used to give closer linkage. The table shows that for plants such as *Arabidopsis*, which has a very small genome, 1 centimorgan represents 139 kilobases, thus chromosome walking from an RFLP marker to a genetic loci is just within the bounds of possibility, given a lot of effort. Doubtless other genes will be isolated in this way from *Arabidopsis* and will then be used as probes to find homologous sequences in other plants. But it seems unlikely that genes governing many complicated plant functions (such as disease resistance) would be similar between *Arabidopsis* and economically important crop plants.

The resolution gap in plants

Species	Genome size (kilobase pairs)	Map length (centimorgan)	Kilobase pairs equivalent to 1 centimorgan	Ref.
Arabidopsis	7×10^4	501	139	10
Tomato	7.15×10^5	1,400	510	1
Human	3×10^6	2,708	1,108	11
Maize	3×10^6	~1,400	~2,140	12

Map lengths are based on published RFLP data. The conversion of centimorgans to kilobase pairs is an average value as recombination frequency varies in different chromosome regions.

For such plants a 'resolution gap' exists between the genetic and the physical map which must be bridged if their genes are to be approached from linked RFLP probes. A similar (although less daunting; see table) resolution gap in the human genome has spurred technical developments such as pulsed-field gel electrophoresis[5] and cloning in yeast artificial chromosomes to handle and map very large pieces of DNA[6,7] as well as the use of 'jumping' and 'linking' libraries to overcome the necessity of walking everywhere in the genome[8,9]. Once the region surrounding the target gene is physically mapped, ways must be found to identify the gene itself. □

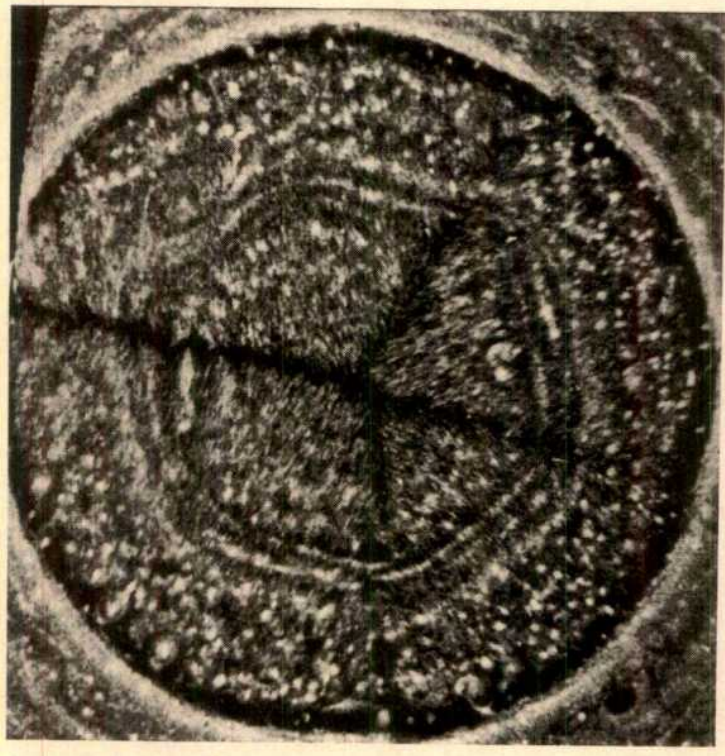
100 years ago



WITH reference to A. C. Haddon's account of the use of the *Remora* or sucker fish by the natives of Torres Straits in fishing for turtles (*Nature*, 17 January, p.285, 1889), I may call attention to the paper on this subject read by Frederick Holmwood, C. B., late H.B.M. Consul at Zanzibar, before the Zoological Society of London, on 17 June 1881, which Haddon does not seem to be acquainted with. Holmwood has fully described the mode of the use of the *Remora* by the native fisherman of Zanzibar in catching turtles and fishes. It is curious to find a somewhat similar method of employing the *Remora* practised by the islanders of Torres Straits.

From *Nature* **39**, 295; 24 January 1889.

Hexagonal polar current on Saturn

THE remarkable hexagonal feature surrounding Saturn's north pole apparent in the figure was discovered by D. A. Godfrey (*Icarus* 76, 335–356; 1988) while making polar projections of Voyager images. The outermost circle is at about 65° latitude and represents the edge of a zonally symmetric current in Saturn's atmosphere. At the time of the spacecraft fly-by in 1981 the northern hemisphere was entering spring and the polar region was sufficiently illuminated to show features, although great care was necessary to remove shading due to twilight effects. The mosaic figure, one of six presented (each showing the hexagon), is made up of four images taken of the sun-lit hemisphere as the planet rotated. Because Voyager's orbit kept it close to Saturn's equator, Godfrey had to reproject the foreshortened images of the north pole to produce the view shown, looking down the planetary axis. The morphology of the clouds does not change a great deal during one 10-hour rotation period, so that the mosaic is not very much different from an instantaneous snapshot. The four 'spokes' are boundaries between images, and the streaked appearance near the pole is an artefact of the projection.

D. A. Godfrey

Small differences between sequential mosaics can be used to determine the drift rate of clouds, and it is here that surprises emerge. The hexagonal feature is an atmospheric jet stream whose position and configuration remain fixed, to within a few metres per second, but the current in the jet exceeds 100 m s^{-1}. In this context, 'fixed' means stationary in latitude at about 76°, and in longitude relative to the periodicities which appear in radio emissions from the planet, presumably linked to the magnetic field which in turn is anchored to the deep core of the planet. Thus this is a jet stream which follows a twisting yet stationary path, rather than meandering, as is the familiar case in Earth's atmosphere and oceans.

Godfrey discusses the possibility of a direct connection between the hexagonal structure and the magnetic field, but concludes that it is improbable. The clouds are ammonia crystals at a level where the atmospheric pressure is about half an atmosphere and the temperature is about 120 K, well within the 'troposphere' (lower atmosphere) rather than the ionosphere. The conductivity is low and magnetohydrodynamic effects should not exist. Also unlikely is a direct connection between the radio emissions and the planetary weather, as these emissions do not have the character of lightning bursts. The simplest idea is that the magnetic field and the atmospheric current both have longitudinal structure that is of deep origin, and hence they show closely similar rotation rates.

Godfrey's kinky current is one more example on a growing list of stationary, or at any rate slowly moving, flow structures on the outer planets. Since the time of Galileo we have known of the Great Red Spot of Jupiter, which drifts in longitude with speeds of only a few metres per second, although it is composed of (and resides in) currents whose speeds reach 100 m s^{-1}. Smaller spots on Jupiter also tend to be slowly moving. T. E. Dowling and A. P. Ingersoll (*J. Atmos. Sci.* 45, 1380-1396; 1988) have shown that the circulation patterns near and within these spots can be used to infer the nature of flows at deeper levels, although they do not point to any particular reason for very slow motion of the spots. And there are slowly moving large-scale thermal features, discovered in the infrared by J. A. Magalhães *et al.* (to be published in next week's *Nature*) located at low latitudes on Jupiter, right where the broad equatorial current is also situated. The current is apparently perturbed by some influence that is nearly stationary.

All of these features could be providing information about deeper regions. Jupiter and Saturn have only small solid cores, unlikely to have any influence on surface motions. The vast bulk of these planets is fluid hydrogen and helium in roughly cosmic abundance. Heat emerges from the interiors in large quantities, comparable to the solar heating. The nature of the fluid motions which carry this heat to the surface has long perplexed astronomers and those studying convection. We may at last be seeing evidence, albeit indirect, for the morphology and flow speeds associated with this convection.

Palaeontology

Fossil reptiles from ancient caves

Michael J. Benton

ONE of the problems of studying terrestrial fossil sites is that large plants and animals seem to be commoner than small ones, whereas the opposite pertains in nature. This could be because organisms were on average larger in the past; or because small ones are less likely to be preserved. The latter explanation seems to be the case as sites have been found, although only occasionally, which contain abundant small fossils. One such is the fossilized cave systems of south Wales and Bristol in the United Kingdom. In a new paper, N.C. Fraser[1] reports the discovery of small animals from an age where most sites reveal dinosaurs and other large animals.

The abundant small beasts of the Bristol–South Wales region offer a fascinating glimpse of life on land beneath the feet of the first dinosaurs. Despite their abundance and the good quality of preservation, the fauna is not perfectly fossilized. The skeletons are found at the bottom of fissures eroded into the ancient limestone hills. As the openings into the fissures are often small, the larger animals have effectively been filtered out. Nevertheless, the fissure animals provide unique

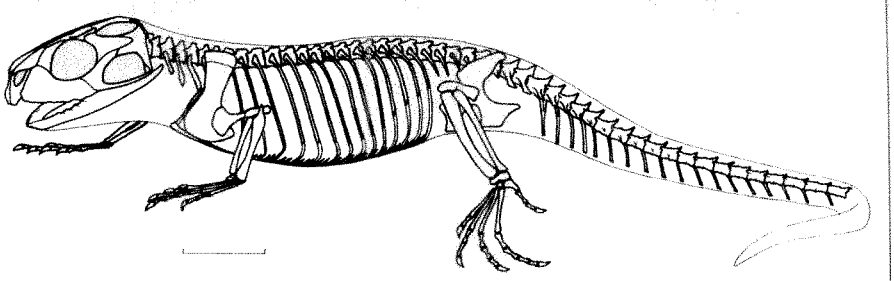

Fig. 1 Composite restoration of the entire skeleton of *C. hudsoni*. Bar, 2 cm. (From ref. 1.)

insights into the lives of the more abundant animals at this time of major faunal turnover. Some of the fissures were under water at the time of fossil formation.

The fossiliferous fissure deposits are dated as Late Triassic to Early Jurassic (about 220–200 million years old), the time during which the dinosaurs became established, and during which most 'modern' land vertebrates arose: mammals, turtles, crocodilians and lepidosaurs. These smaller 'modern' vertebrates are best represented in the fissures and they have yielded significant new phylogenetic information.

Fraser's find[1] of the sphenodontid *Clevosaurus hudsoni*[2] allows him to perform a detailed analysis of this animal and of its relationship with other organisms. *Clevosaurus*, a small 250-mm-long reptile, is superficially like a modern lizard, with a slender body, long limbs and (probably) a long tail (Fig. 1). The teeth are chisel-like and, unusually for a vertebrate, fused firmly to the bone of the jaws (Fig. 2). The teeth and jaw bones of adult specimens of *Clevosaurus* show signs of heavy wear, and the jaw action was a shearing one, rather like the action of a well-adjusted pair of scissors. *Clevosaurus* probably fed on hard-skinned invertebrates such as centipedes, insects and snails. It may also have been a facultative herbivore, raking plant food together with its beak-like front teeth, and chopping it further back in the mouth. Young *Clevosaurus* specimens have small, sharp teeth which may have been used for eating soft-bodied invertebrates such as worms.

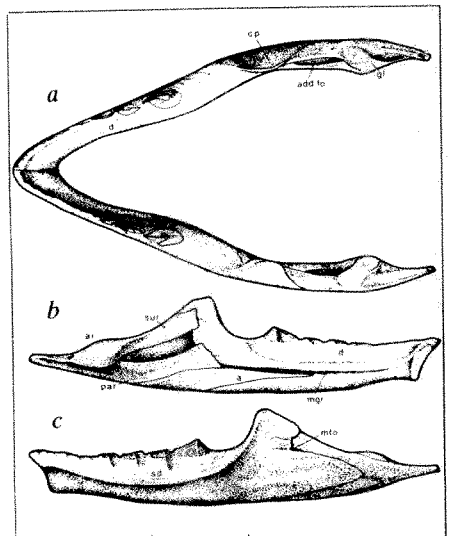

Fig. 2 Composite restoration of the mandible of *C. hudsoni* in: *a*, dorsal; *b*, medial; *c*, lateral views. Scale bar, 1 cm. (From ref. 1.)

Fraser[1] distinguishes two or more species in his material of *Clevosaurus*. The material is mainly disarticulated, and he examined more than 1,000 separate bones. Fortunately, he found a few more complete specimens which helped in the identification of isolated elements. The second *Clevosaurus* species, *C. minor*, is much smaller than *C. hudsoni*, reaching an estimated total length of 150–200 mm. They have adult patterns of tooth wear, so are unlikely to be juveniles of *C. hudsoni*. *C. minor* is found at different sites from *C. hudsoni*, so they are probably independent breeding species.

Other associated vertebrates from the Triassic fissures[3] include a gliding reptile, *Kuehneosaurus*; the early crocodilian *Terrestrisuchus*[4]; the dinosaur *Thecodontosaurus*[5]; the very early mammal *Kuehneotherium*[6]; various unidentified archosaurs[7]; and up to ten species of sphenodontid[1,8–10]. The Jurassic fissures contain a rather different fauna, consisting of the mammal *Eozostrodon*, the tritylodont *Oligokyphus*, the lepidosaur *Gephyrosaurus* and fish teeth[8].

The sphenodontids, such as *Clevosaurus* and its kin from the fissures, are of great phylogenetic importance. They are broadly similar to the living tuatara *Sphenodon* from New Zealand, a so-called living fossil. The fact that a complex fauna of up to ten sphenodontids co-existed in the south-west of Britain 220–210 million years ago suggests that the group was once as flourishing as the lizards are today[10]. □

Daedalus

If I had a hammer

THE hammer is one of the most basic of implements. It exploits a simple newtonian principle: the deceleration of its head imposes a force on the object it strikes. In the hands of a skilled craftsman, it can crack a brick precisely in two, or make a controlled adjustment of 0.01 millimetres.

In the hands of unskilled amateurs, however, it produces a vast global total of bent nails, bruised thumbs, dented woodwork and smashed panes of glass. Daedalus is therefore updating this palaeolithic invention with the most advanced electronics. He has been inspired by the modern thyristor photographic flash unit. This integrates the light reflected off the scene and, when enough has been received for a good exposure, quenches the flash. It all happens in microseconds. In the same way, Daedalus's electronic hammer carries an accelerometer which integrates the momentum received by the target during the impact. When this exactly reaches a pre-set value, the impact is 'switched off'. A fast-acting trigger mechanism snatches back the hammer head and dumps the surplus momentum back into the handle and the user's arm.

This wonderful tool not only tames and directs the enthusiasm of the user: it educates him too. Set for a delicate task (such as tapping a ceramic tile into place on its mortar) it will transmute a wild swipe into a light and precise blow. But the excess momentum, returned to the user's arm as an unexpected 'kick', warns him that his blow was too heavy. His next swipe will not be so wild. Soon he will have a sound intuitive feeling for the exact use of the hammer in this task. Professionals and amateurs alike will welcome the electronic hammer: in all fields of engineering and domestic construction it will teach the subtle kinetic intuition of the true craftsman. Indeed, electronically controlled impact may become the preferred way of carrying out all sorts of tasks now conducted manually, from removing a stopper to advancing a pawn or shaping a cake. Daedalus is devising a 'personal electronic hammer' to fit in the pocket like a pen. The user will turn to it for any manual task as automatically as he reaches for a pen to write with, or a calculator to do arithmetic.

But the best strategy for developing a new invention is to launch a high-value product first, on whose profits the mass market can be attacked. So Daedalus's first commercial product will improve the most valuable impacts of them all — those of international golf. His electronic golf clubs, bringing calibrated exactitude to this most obsessive and unforgiving of games, should sell for tens of thousands of pounds.

David Jones

Setting radiation standards

SIR—The setting of standards of protection against ionizing radiation, already controversial, is being confused by the difficulty of specifying clearly the significance of the risk to an exposed individual. 'Risk' is used here to mean the probability of a deleterious event. The term 'detriment' can be used to combine the probability and the severity of that event.

For many years, the fatal risk to an individual has been presented as the probability of attributable death with no allowance for competing causes of death. The effect of this allowance is known, but has not been used explicitly in setting standards. The effect of latency on the degree of detriment has also been neglected, although a death in later years is less detrimental than an earlier one.

More recently, in its 1988 report to the UN General Assembly[1], the United Nations Scientific Committee on the Effects of Atomic Radiations (UNSCEAR) has addressed both these issues. The allowance for competing causes of death is explicitly included in the risk estimates, and the effect of latency on the detriment is indicated by estimating the average years of life lost. Information on the distribution of risk with time after exposure is still incomplete because many members of the exposed populations being studied are still alive. UNSCEAR offers two risk-projection models, one with the risk constant (after a latent period) — an additive model — and the other with the risk increasing with time as does the risk of 'natural' cancer — a multiplicative model. The letter predicts about twice as many deaths as the former with no more years of lost life. Unfortunately, most commentators on this topic have stressed the increase in fatal risk without considering the decrease in years lost per attributable death.

There is a further weakness in using risk alone. The total risk of death cannot be increased; it is unity. Radiation can change the time and cause of death, not the overall probability.

The risk to the individual is thus a poor measure of the consequences of exposure to ionizing radiation. We need a multi-attribute approach to take account of the time and nature of a death in addition to its probability. This would also make it easier to include explicitly the non-fatal effects such as curable cancer and hereditary defects. It is to be hoped that those reponsible for setting standards, particularly dose limits, will not rush into changes based only on the simple concept of risk. As both the International Commission on Radiological Protection[2] and the National Radiological Protection Board[3] have indicated, the most appropriate immediate reaction is to increase the attention paid to the need to keep all exposures as low as can reasonably be achieved. Quantitative changes in standards should be a more measured response.

X-chromosome reactivation and ageing

SIR—At first sight it seems that the results of Migeon *et al.*[1] on the low reactivation frequency of the human X-linked hypoxanthine phosphoribosyl transferase (HPRT) gene do not confirm the earlier finding of the strong age-related reactivation of the mouse X-linked ornithine carbamoyl transferase gene (OCT)[2]. Whereas the spontaneous reactivation of the silent OCT gene was increased 50-fold in mice older than one year, the reactivation of the silent human HPRT gene in female Lesch–Nyhan heterozygotes is rare at any age.

In studies of the process of ageing, one of the main challenges is to understand how similar physiological or biochemical events occur at very different rates in species with different lifespans. For example the crosslinking of collagen is known to increase with age, but although the chemistry is the same, the rates of reaction are very different in different species[3]. The same is true for the accumulation of the age pigment lipofuscin, the denaturation of lens crystallin and other 'biomarkers' of ageing, as well as many pathologies, including the appearance of neoplasms. It is well known that mouse cells transform to malignant cells readily in culture, whereas human cells are very refractory to this transformation. This makes biological sense, because on a per cell basis, small short-lived animals have a far higher incidence of cancer than large long-lived ones.

It is therefore reasonable to argue that the age-related reactivation of a silent X-linked gene would be many times higher in mouse cells than in human cells. Another way of saying the same thing is that the controls of cellular metabolism, or cellular homoeostasis, must be very much tighter in long-lived animals than in short-lived ones, and this would of course include the silencing of gene expression by DNA methylation[4]. It is already known that the maintenance of cytosine methylation in DNA in primary diploid cells is much more effective in human than in mouse cells, and that hamster cells have an intermediate level of maintenance[5].

Two of the results reported by Migeon *et al.* together indicate that there may be a low loss of methylation in normal human cells with ageing.

First, there is a slight increase with age in the proportion of cells with active HPRT, which is an insensitive assay, and the results are of marginal statistical significance ($P=0.08$).

Second, using a much more sensitive assay, it is shown that the silent HPRT gene can be more easily reactivated by the demethylating agent deoxyazacytidine in cells from old individuals than in cells from young ones ($P<0.005$).

These results would be expected if the methylation of many sites in the CpG-rich island of the human HPRT gene declines slowly with age, but the overall silencing mechanism is fairly efficiently maintained. However, a gradual loss of methylation would increase the probability of reactivation by a demethylating agent. If this interpretation is correct, then similar experiments carried out with female 'Lesch–Nyhan' heterozygous mice[6,7], should show a significant age-related reactivation of HPRT. Such a result would reinforce the view that cellular homoeostasis is much better maintained in long-lived species than in short-lived ones[4,8].

Misidentified cell

SIR—Because the cell line TE671 is said to originate from an early culture of a human medulloblastoma[1], it has been widely used to investigate this tumour type and as a model for primitive neural cells in general. And because the cell line can be infected by the AIDS virus HIV[2] (in a way that cannot be blocked by soluble CD4, as reported on page 368 of this issue[3]), TE671 could provide an ostensibly useful *in vitro* model of HIV infection of the brain. Our evidence, however, suggests that TE671 is not a neural cell but a muscle cell.

We note that TE671 cells have a number of features in common with the rhabdomyosarcoma cell line RD. They have several of the phenotypic characteristics of striated muscle cells, including the presence of desmin, myoglobin[4] and the

muscle-type acetylcholine receptor[5]. We have found that both cell lines contain an N-*ras* gene that is activated by a point mutation at the third base of codon 61 and, in new cell stocks obtained directly from the American Type Culture Collection, that the majority of marker chromosomes are common to the cell lines. Furthermore, DNA fingerprinting with locus-specific and core probes fails to reveal differences between the two lines.

Both cell lines were derived in the same laboratory but RD was described[6] and submitted to the ATCC before the first report of TE671. When considered together these observations indicate that TE671 is most probably a subline of the rhabdomyosarcoma cell line RD.

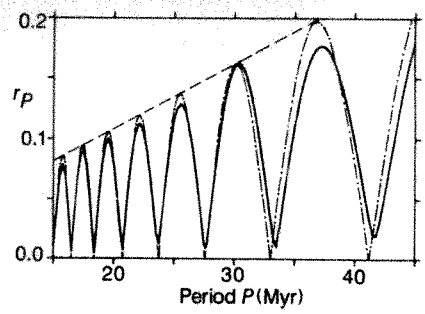
Spectral peaks

SIR—Lutz and Watson[1] discuss the frequency spectrum of the Harland *et al.*[2] geomagnetic reversal record of the past 165 million years. This spectrum has been interpreted as showing a 30-million-year short-term oscillation superimposed on an aperiodic long-term variation. Lutz and Watson argue that the long-term component, $\lambda_L(t)$, dominates the frequency spectrum for periods P up to 40 million years. Here I show that the spectrum in this range is essentially determined by the strong boundary discontinuities introduced by performing a Fourier transform $\lambda_L(t)$ over a finite interval (τ_1, τ_2); that is, these discontinuities dominate over any time variation of $\lambda_L'(t)$ between τ_1 and τ_2.

The influence of discontinuities becomes apparent when the limits of the Fourier transform are extended to $(-\infty, +\infty)$. This leaves all integrals unchanged, provided that the 'extended' function $\lambda_L'(t)$ has the form

$$\lambda_L'(t) = \begin{cases} \lambda_L(t) \text{ for } \tau_1 \leq t \leq \tau_2 \\ 0 \text{ otherwise} \end{cases} \quad (1)$$



As $\lambda_L(t)$ is largest at the boundaries, $\lambda_L(t)$ exhibits large discontinuities there. The dominance of these discontinuities can be demonstrated by considering a simplified trial function

$$\lambda_L^0(t) = \begin{cases} \lambda_d = \text{constant for } -T/2 \leq t \leq T/2 \\ 0 \text{ otherwise} \end{cases} \quad (2)$$

which retains the two boundary discontinuities (of size λ_d, taken to have the value 5 Myr^{-1}, and separation $T = \tau_2 - \tau_1$) but carries no information on variations in between. The spectrum of this function,

$$R_P^0(T) = N^{-1}\lambda_d (P/\pi) \left| \sin(\pi T/P) \right| \quad (3)$$

is compared in the figure with that of $\lambda_L(t)$ obtained by Lutz and Watson[1]. (Here N is the total number of reversals.) We interpret the close correspondence in shape, position and peak heights as verification of our initial claim. The straight dashed line denotes the exact small-P asymptotic envelope for any function $\lambda(t)$ that has the same discontinuities as $\lambda_L'(t)$ and $\lambda_L^0(t)$. The positions of the maxima of $R_P^0(T)$ are given by $P_n \approx T/(n+1/2)$ for integers $n \geq 0$; for all T, they agree well with the values from the numerical Fourier transform of $\lambda_L(t)$ given in Table 1 of ref. 1, for which τ_1 was varied in discrete steps. Therefore, the grouping together there of peak positions with more or less constant period is arbitrary. When $\tau_2 - \tau_1$ decreases continuously, the peak positions do so too.

Fourier spectra of two long-term reversal functions plotted against period $P = 2\pi/\omega$. $R_P^1(\tau_1, \tau_2)$, from ref. 1, is shown as a solid curve, and $R_P^0(T)$ (equation (3)) as a dash-dotted line. The straight dashed line is the exact asymptotic envelope for $P << T$ to both spectra.

The influence of short-term oscillations would thus be seen only as noticeable deviations of the peak heights from those of $R_P^0(T)$, that is, from the envelope of R_P (τ_1, τ_2). Using a Poisson process, Lutz and Watson[1] show that the long-term component alone may generate fluctuations in the peak heights that are large enough to account for the spectrum of the total reversal function $\lambda(t)$.

Thus, for periods $\lesssim 40$ Myr, the spectrum R_P (τ_1, τ_2) of the total reversal function is determined mainly by the strong discontinuities in $\lambda_L(t)$ at τ_1 and τ_2, and hides any information on short-term variations. These can be reliably detected in the spectrum only if the discontinuous long-term variation can be subtracted before the Fourier transform operation.

RNP in maize protein

SIR—We wish to point out an interesting feature in the sequence of the abscisic acid-induced glycine-rich protein (AAIP) of maize recently reported by Goméz *et al.*[1]. The protein contains a sequence (see below) which conforms perfectly to the RNP consensus sequence[2-4] that has been found so far in heterogenous nuclear RNA-, messenger RNA-, pre-ribosomal RNA-, and small-nuclear RNA-binding proteins.

Maize AAIP:

$\cdots$ Arg^{49} Gly Phe Gly Phe Val Thr Phe^{56}...

RNP consensus sequence:

... Lys Gly Phe Gly Phe Val Thr Phe...
Arg Tyr Ala Tyr X Tyr

This strongly suggests that AAIP is a single-stranded nucleic-acid binding protein, most probably an RNA-binding protein (RNP). Several other features of the AAIP sequence also resemble those found in some of these proteins. The protein appears to contain two distinct domains: an amino-terminal domain (about 90 amino acids) that contains the RNP consensus sequence, and a carboxy-terminal glycine-rich domain. The amino-terminal domain is the putative RNA-binding domain[4]. There are extensive similarities in the general character of the amino-terminal domain with that of the putative RNA-binding domain of several RNP proteins[4]. A glycine-rich domain is also a feature of some RNP proteins (for example, the hnRNP protein A1 (ref. 5), and the nucleolar protein nucleolin[6]). AAIP may be the first plant protein described so far to contain an RNP consensus sequence. The predicted property of AAIP as an RNA-binding protein can be readily tested, for example, by chromatography on small-subunit DNA columns, on ribohomopolymer columns, and by photochemical crosslinking to RNA.

Abscisic acid is a hormone that appears to modulate the response of plants to adverse conditions, and it seems to also play a role in embryogenesis. Determining if AAIP is indeed an RNA-binding protein, and if so, what RNA it binds to should be important for understanding the mechanism of these important processes.

Authoritative coverage of vital research issues...

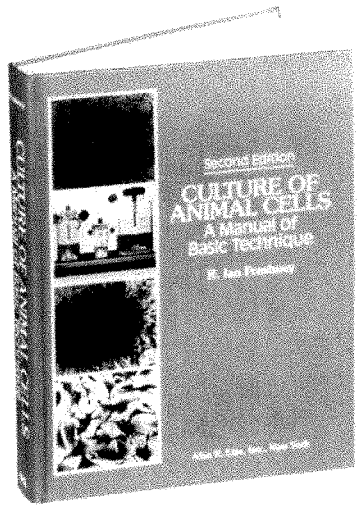
CELL MOVEMENT
Volumes 1 and 2

Cell Movement, a two-volume set, develops both the similarities and differences between two groups of proteins, the study of whose characteristics and behavior has contributed to the development of modern cell biology.

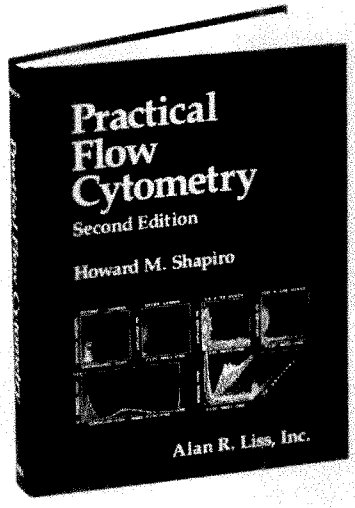
Volume 1: The Dynein ATPases
Fred D. Warner, Peter Satir, and Ian R. Gibbons, Editors
ISBN 0-8451-4266-6 • LC 88-23027 • Publication: 1988 • 356 pages, $88.00

Volume 2: Kinesin, Dynein, and Microtubule Dynamics
Fred D. Warner and J. Richard McIntosh, Editors
ISBN 0-8451-4267-4 • LC 88-23027 • Publication: 1989 • 492 pages, $98.00

CULTURE OF ANIMAL CELLS
A Manual of Basic Technique, Second Edition
R. Ian Freshney



The **Second Edition** of Freshney's manual updates and considerably expands the scope of its predecessor and still enables both the novice and the experienced researcher to apply the basic and more sophisticated techniques of tissue culture. Well-written theoretical discussions help the reader to assess the role of cell cultures as models for *in vivo* processes. In addition, new, extensive protocols, and improved serum-free media coverage, enable the reader to perform numerous, more specialized procedures without consulting additional literature.



ISBN 0-8451-4241-0 • LC 87-3313 • Publication: 1987 • 416 pages, $59.50

PRACTICAL FLOW CYTOMETRY
Second Edition
Howard M. Shapiro, M.D.

The **Second Edition** of this volume updates and considerably expands the scope of its predecessor, serving as the *complete* reference on flow cytometry. Clear and comprehensive, this highly readable text enables flow cytometry users – biomedical researchers, workers in biotechnology, and researchers in clinical laboratories – to easily evaluate and perform new techniques and applications of flow cytometry – without having to consult additional literature.

ISBN 0-8451-4254-2 • LC 88-9486 • Publication: June 1988 • 370 pages, $59.50

SELF-ASSEMBLING ARCHITECTURE
Joseph E. Varner, Editor

Self-Assembling Architecture presents a unique, comparative approach to understanding the basic mechanisms and rules of self assembly in biological systems. This comprehensive volume examines some illustrative examples of molecular architecture, building on data obtained from previous studies on the assembly of some well understood hierarchical structures such as tobacco mosaic virus, as well as more complicated macromolecular assemblies.

46th Symposium of the Society for Developmental Biology • ISBN 0-8451-1507-3 • LC 88-25553 • Publication: December 1988 • 288 pages, $65.00

RECEPTOR BIOCHEMISTRY AND METHODOLOGY

J. Craig Venter and Len C. Harrison, Series Editors

Receptor Biochemistry and Methodology is devoted to the molecular advances involved in understanding the structure and biochemical basis of receptor action as well as detailing the necessary methodologies for receptor studies. This comprehensive series is comprised of articles that are not only excellent reference sources on the study of integral membrane proteins but also extremely useful at the laboratory bench. The information here is essential to researchers undertaking the molecular characterization of receptors or other integral membrane proteins.

Volume 13: Receptor Localization: Ligand Autoradiography

Frances M. Leslie and C. Anthony Altar, Editors

ISBN 0-8451-3712-3 • LC 88-8275 • Publication: November 1988 • 236 pages, $79.50

ADVANCES IN BIOTECHNOLOGICAL PROCESSES

Avshalom Mizrahi and Antonius L. van Wezel, Editors

". . . a series that presents comprehensive reviews of current developments and applications in biotechnology and includes information on the nature, scope, detailed steps, ideas, and policies on the reviewed products and processes. . . ."

ASM News
Volume 50, Number 6, 1984

Volume 11: Monoclonal Antibodies: Production and Application

Avshalom Mizrahi, Editor

ISBN 0-8451-3210-5 • LC 83-644876 • Publication: October 1988 • 434 pages, $96.00

Volume 10: Synthetic Peptides in Biotechnology

Avshalom Mizrahi, Editor

ISBN 0-8451-3209-1 • LC 83-644876 • Publication: October 1988 • 256 pages, $69.50

PLANT BIOLOGY

Nina Strömgren Allen, Series Editor

Plant Biology is a new series intended to further our understanding of plants, a vital part of our environment. This series is designed to keep researchers, students, and teachers abreast of the latest developments in plant biology.

Volume 6: Second Messengers in Plant Growth and Development

Wendy F. Boss and D. James Morré, Editors

ISBN 0-8451-1805-6 • LC 88-22966 • Publication: December 1988 • 360 pages, $96.00

Volume 7: Algae as Experimental Systems

Annette W. Coleman, Lynda J. Goff, and Janet R. Stein-Taylor, Editors

ISBN 0-8451-1806-4 • LC 88-37733 • Publication: February 1989 • $70.00

ADVANCES IN MEMBRANE FLUIDITY

Roland C. Aloia, Series Editor
Cyril C. Curtain and Larry M. Gordon, Associate Series Editors

With the rapid experimental progress in membrane fluidity, the need for an authoritative source of information on all aspects of membrane research is clear. **Advances in Membrane Fluidity,** an important new book series, presents in-depth volumes, each focusing on a specific topic, covering membrane biology, biochemistry, and biophysics in a comprehensive and detailed manner.

Volume 1: Methods for Studying Membrane Fluidity

ISBN 0-8451-4600-9 • LC 88-6798 • Publication: July 1988 • 338 pages, $120.00

Volume 2: Lipid Domains and the Relationship to Membrane Function

ISBN 0-8451-4601-7 • LC 88-9979 • Publication: August 1988 • 312 pages, $120.00

Volume 3: Physiological Regulation of Membrane Fluidity

ISBN 0-8451-4602-5 • LC 88-780 • Publication: May 1988 • 379 pages, $120.00

TISSUE ENGINEERING

Richard Skalak and C. Fred Fox, Editors

Tissue Engineering provides a unique, comprehensive overview of the rapidly emerging applications of the principles and methods of biomedical engineering and biotechnological research to structure-function relationships in normal and pathological mammalian tissues. With emphasis on the development of biological substitutes to restore, maintain, or improve tissue functions, the book reviews the benefits and challenges of this novel technology and highlights the practical biomedical applications that have promising outcomes for improving the quality of life.

UCLA Symposia on Molecular and Cellular Biology, New Series, Volume 107 ISBN 0-8451-4706-4 • LC 88-26675 • Publication: December 1988 • 366 pages, $60.00

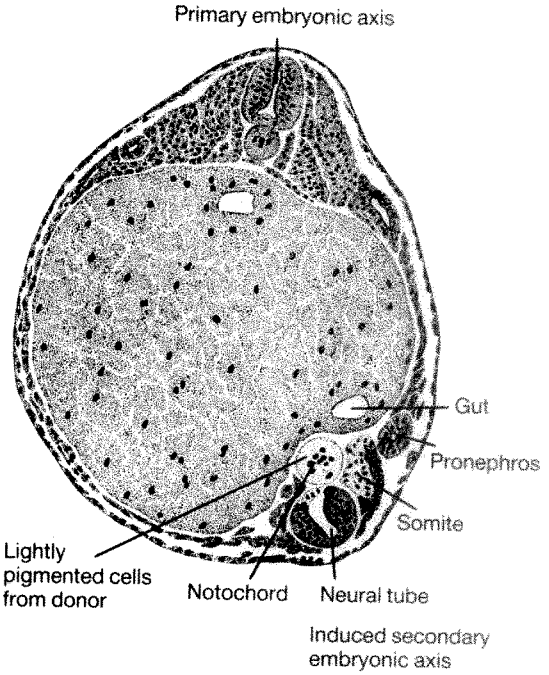
Prized developmentalist

Tim Hunt

The Heritage of Experimental Embryology: Hans Spemann and the Organizer. By Viktor Hamburger. *Oxford University Press: 1988. Pp. 196. £22.50, $29.95.*

VIKTOR Hamburger, as old as the century, was a graduate student in Hans Spemann's laboratory in Freiburg. He was an exact contemporary of Hilde Mangold (*née* Proescholdt), who performed the famous 'organizer experiment' (see figure) that clinched Spemann's reputation and won him the only Nobel prize ever awarded for developmental biology. Over 30 years later, in St Louis, Missouri, Hamburger was head of the laboratory in which nerve growth factor and epidermal growth factor were discovered by Rita Levi-Montalcini and Stanley Cohen, work that in turn won them a Nobel prize. It is clear from Levi-Montalcini's account of this period that Hamburger was all that a boss should ever be, encouraging, supportive, insightful and critical, and only his perfect modesty explains why he is not as celebrated as his erstwhile mentor or his own pupils.

Hamburger's account of Spemann and the organizer is a masterpiece. "No subject in embryology has been so misrepresented and misunderstood as the properties of the organiser" according to Jonathan Slack[1], but Hamburger does a superb job of explaining the experiments, setting them in historical context and tracing their subsequent experimental and analytical history. Anyone with the faintest interest in developmental biology should read this book. It is an eye-opening inspiration.



The purely scientific account is enlivened by biographical sketches of the protagonists, done with graceful affection and respect. An appendix describes Hilde Mangold and brilliantly evokes student life in Freiburg in the early 1920s. We discover that the PhD students actually had to know some philosophy, attending lectures by Husserl and Heidegger. The political climate was violent, the inflation appalling, yet the arts flourished and the mountains frequently called the young away to relax; no wonder such great work was done. And although they "cared more for food for thought than nourishment for our bodies", the dreadful "turnip winter" put them off that vegetable for life.

Hamburger was close to Hilde Mangold, who alas died in 1924 from burns sustained when a petrol heater exploded at home. She had not been pleased when Spemann insisted on putting his name on her paper (and first at that); but according to Hamburger, the design and conception of the experiments were Spemann's and Mangold was the fortunate student assigned to carry them out. She died before her work became widely appreciated.

Hamburger analyses these classical experiments and ideas in developmental biology as clearly as I have ever seen it done, and traces Spemann's scientific legacy almost to the present day. He points out errors, ambiguities and misconceptions as well as describing the technical problems that beset the early workers. Spemann, it turns out, did not appreciate the importance of the ionic composition of the medium for the survival of his embryos (at one time he had to send back to Würzburg for water to make things work; calcium was probably the missing ingredient). It was Johannes Holtfreter who discovered the importance of this and of the need for scrupulous sterility, which allowed him to perform much more sophisticated experiments. Nowadays, antibiotics assure the embryos' well-being, and advances in reproductive physiology mean that experiments do not have to attend on the natural breeding season of the animals.

Nevertheless, Spemann was a great craftsman. His use of baby's hair for the 1904 constriction experiments is legendary, and he invented all sorts of other useful tools for cutting and transplanting bits of the tiny embryos. Moreover, his analytical acumen matched his experimental powers, and though he confessed to a preference for "psychical" rather than physical metaphors in the analysis of his data[2], he was never carried away by more abstract theory of the kind that led Driesch ultimately to espouse vitalism. In his imagination Spemann was at one with the objects of his study, which allowed him and his followers to extract the maximum of clear information from their transplantation experiments. As Walther Vogt, the great fate-mapper, explained at Spemann's sixtieth-birthday celebration: "The result is not sought by theorizing, thus passing over the object; nor by treating the embryo as a pure object, but rather by questioning it like a living partner, in a dialogue".

Spemann was no chemist, nor yet a physiologist (as the story of the water makes clear), and only towards the end of his career did the search for a chemical embodiment of the organizer begin, with mixed results. Spemann had regarded the inductions he studied as properties of whole tissues, and barely even considered organization at the cellular level. What had impressed him was that an almost complete second embryo could be induced simply by transplanting a tiny sliver of tissue from one embryo into another. This is curiously holistic biology,

The organizer experiment — Spemann summarized the experiment as "The astounding fact that a secondary embryo may be brought about by transplantation". The upper edge of a blastopore from a lightly pigmented newt gastrula was transplanted to the side of a gastrula of a different species of newt with dark pigmentation, giving a gastrula with two blastopores. The graft 'took' and invaginated at its new site. The resulting embryo had two neural plates, two sets of somites, two guts and so on as can be seen in the cross-section shown here. The pigmentation marker showed that the secondary embryo was composed of cells derived from both donor and recipient tissues. Hence the implant was said to 'organize' a secondary embryonic axis running along the flank of the recipient. This property is confined to the upper edge of the blastopore. It is perhaps the most striking known example of embryonic induction. The illustration, which has been relabelled, is taken from Embryonic Development and Induction, *by Hans Spemann (Yale University Press, 1938).*

yet meticulously and rigorously dissected on its own terms, as Hamburger makes plain.

What is fascinating and puzzling about this period as seen with modern eyes is the apparently complete lack of communication between geneticists and developmental biologists. T.H. Morgan and his colleagues had laid out the basis of modern genetics by the end of the First World War, and Morgan himself was familiar with the main issues in developmental biology through working in marine stations at Naples and Woods Hole. Yet in his 766-page book *Experimental Embryology* (1927), Morgan devoted a scant four pages to the role of chromosomes in development. Too little was known — "Whether all the genes are active all the time, or whether some of them are more active at certain stages of development than are others, are questions of profound interest". Nor was it then certain whether the chromosomes were "concerned with the making of enzymes". Morgan also devoted considerably less space to embryonic induction than he did to parthenogenesis, but that is another story.

I would be curious to know whether Spemann and his school ever thought about how genes might shape the tissues, or what kind of form they imagined a complete account of embryonic induction would eventually take. Of course, in the mid-1920s there was little enough known about proteins and enzymes, let alone how genes might control their production. Given this ignorance, it is amazing how far the analysis of determination, differentiation and induction could progress, and a revelation to modern molecular eyes to see how much there is still to explain. My only regret about Hamburger's book is that it stops short of the cloning revolution, and sticks closely to amphibian development. It would be marvellous to hear his views on induction, fields and gradients in their modern dress. □

Condensed matter

W. R. A. Brown

Heterochromatin: Molecular and Structural Aspects. Edited by Ram S. Verma. *Cambridge University Press:1988. Pp.301. £30, $49.50.*

AT THE end of a eukaryotic mitosis, most of the chromatin in the cell decondenses. Some does not and remains genetically inactive — this material, with its distinctive cytological properties, is called heterochromatin.

Until recently there has been a gap between the chromosomal features that can be described with the help of a microscope and the size of DNA amenable to molecular analysis. Now, however, pulsed-field gel electrophoresis and molecular cloning in artificial yeast chromosomes are making it possible to analyse megabase pair stretches of DNA, and thus to develop molecular maps of entire eukaryotic chromosomes. These maps will include the structural information necessary for analysis of eukaryotic chromosome behaviour at a molecular level, a prospect which has brought back to prominence an older, sometimes arcane, cytogenetic literature which depicts a eukaryotic chromosome biology of extraordinary diversity. A further consequence has been the resurgence of interest in a variety of dormant cytogenetical questions, such as those surrounding the functional significance of constitutive heterochromatin.

Heterochromatin is a multi-author volume which sets out to give a contemporary overview of the subject. Appearing as it does at this singular time, it is likely to attract considerable attention. Sadly, in my view, most readers will find it a disappointment.

The first chapter, "The Biology of Heterochromatin" by B. John, occupies nearly half of the book and is an account of the cytogenetics of heterochromatin in animals. Position-effect variegation, segregation distortion, ectopic pairing, heterochromatin elimination and more are reviewed critically. If you need a guide to the older cytogenetic literature, then this is it.

The remaining six contributions can be considered in three groups. A. Lohe and P. Roberts review the sequence organization of satellite DNA in *Drosophila melanogaster* and other *Drosophila* species; this chapter will be of particular value to those working either on other aspects of *Drosophila* biology or on the satellite DNA of other organisms. The next three chapters describe aspects of our knowledge of the ultrastructure of heterochromatin. Here there is duplication and unresolved contradiction, and it would have been better to have had this interesting and apparently controversial area covered in a single authoritative article. The last two contributions describe two rather specialized aspects of human cytogenetics, the first dealing with the use of restriction endonucleases as reagents to help produce banding patterns in human chromosomes, the second with the techniques for detecting human chromosome heteromorphisms.

Altogether this is an uneven book, both in organization and in the quality of the contents. Much is omitted. The discussion of satellite DNA in *Drosophila* is useful, but why is there no general review of tandemly repeated, simple-sequence DNA in other organisms? The molecular basis of mammalian X-chromosome inactivation is covered only briefly. Heterochromatin in plants is mentioned only in passing. Thus the editor has failed in his goal of putting together a comprehensive account of the subject. Nevertheless John's review alone justifies publication of the book, and will ensure that it has a part in the revitalization of the study of heterochromatin. □

W. R. A. Brown is in the Cancer Research Campaign Chromosome Molecular Biology Group, Department of Biochemistry, University of Oxford, Oxford OX1 3QU, UK.

Swooping down the ages — a flying machine, made of natural materials, and based on drawings of Leonardo da Vinci. The machine features in the Leonardo exhibition which opens at the Hayward Gallery, London, today. The book-of-the-exhibition ("an invaluable guide to Leonardo's universe") is also published today by Yale University Press.

Volumes of human learning on machine learning

Max Bramer

Proceedings of the Fifth International Conference on Machine Learning. Edited by John Laird. *Morgan Kaufmann: 1988. Pp. 467. Pbk $24.95. In Britain distributed by Afterhurst, 116 Pentonville Road, London NW1 9JB, £19.95.*

EWSL 88: Proceedings of the Third European Working Session on Learning. Edited by Derek Sleeman. *Pitman: 1988. Pp. 263. Pbk £25.*

ARTIFICIAL intelligence (AI) is the branch of computer science concerned with developing systems with sophisticated reasoning capabilities — capabilities which, if possessed by human beings, would be described as intelligent. A decade ago AI was seldom heard of outside the research laboratory or the realms of science fiction. The turning point came in 1981 with the setting up in Japan of the ten-year programme to build 'fifth generation' computers for the 1990s, in which "intelligence will be greatly improved to approach that of a human being".

Although it may have seemed a heretical idea at that time, AI systems (for problem solving, computer vision, natural-language processing and other applications) are becoming part of the mainstream of computing. There are now hundreds (maybe thousands) of so-called expert systems for practical use in medicine, geology, chemistry and, increasingly, finance. Essentially, the construction of an expert system involves the elicitation of knowledge from a subject expert and its representation in a computer program, often in the form of rules. Obtaining such knowledge is often a time-consuming and error-prone activity, however, and increasingly attention has turned to finding ways in which this process may be automated. Such considerations provide one — although by no means the only — motivation for the recent resurgence of interest in machine learning.

Human intelligence

Although the exact nature of human intelligence remains unclear (and is likely to do so for a long time), the ability to learn is undoubtedly a crucial element, and a multi-faceted one. To list only some possibilities, human learning can be by rote, by trial and error, by discovery, by generalizing from a series of example cases or by a detailed analysis of a single specific case. Humans can learn by self-instruction or by being taught. Teaching can take the form of imparting an underlying theory and/or showing examples of good (or bad) practice.

Much human learning takes place by generalizing from a series of examples. There are many ways in which this can occur: the examples can be presented in a carefully chosen sequence by a teacher, can be chosen at random or in some situations can be self-selecting (for example, patients attending a doctor's surgery). The learner can examine a collection of examples as a whole to develop a strategy for all future cases, or can begin with a simple strategy which is then refined incrementally from further examples as he or she goes along. These and other aspects (such as inductive reasoning) of the human skill known as learning are reflected in the lines of research currently being pursued in machine learning.

Two forms of machine-learning research for which the link with human behaviour is less apparent are 'connectionist' and 'genetic' learning. Connectionist learning is closely related to work on neural nets, a field which has become a bandwagon in the past year or so. Although some interesting results have emerged, it is difficult to evaluate the work concerned without considering the very strong claims which many of its proponents have made about modelling the physiological workings of the human brain. Such claims are notoriously easy to make, but much more difficult to justify. I myself remain unconvinced by them.

The term 'genetic' learning originates from the observation that natural (biological) selection can be regarded as a form of learning, where a simple yet powerful learning strategy is applied repeatedly to a continuous stream of input, whilst the system moves from a rudimentary state (such as a simple single-cell organism) to increasingly more effective ones (such as *Homo sapiens*). In machine learning, genetic algorithms embody some model of natural selection and genetics as their principal learning mechanism. Such algorithms have successfully been applied to tasks like the evaluation of the worth of a position in a game of checkers. Unfortunately, as with connectionist learning, the systems that result are likely to be inscrutable to people, however well they perform their given tasks.

The books under review are the proceedings of two conferences which took place in 1988. That edited by John Laird contains papers presented at the University of Michigan in June; 49 contributions are included, the overall stress being on theory rather than applications.

The way that conference proceedings are broken down into sections is often a good indicator of the balance of research in a particular field at a particular time. In this case, there are 15 papers on empirical learning, seven on explanation-based learning, one on case-based learning, five on machine discovery, four on connectionist learning, five on genetic learning, three on integrating explanation-based and empirical learning, and nine on other topics. Of particular interest are a number of contributions on the well-known ID3 algorithm for constructing decision trees from large collections of examples, a technique which has been strongly advocated as a powerful way for developing the decision rules to use in expert systems.

Goals and experiments

The EWSL proceedings, which come from a meeting held in Glasgow in October, contain 21 papers. Unfortunately they have not been grouped into sections and have simply been arranged in alphabetical order of author, thus losing whatever structure they had when presented at the conference. As a result two valuable, general articles are buried in the middle of the text when they could usefully have been placed at the beginning as an introduction. These are Donald Michie's "Machine Learning in the Next Five Years", in which he considers the past, present and future of the subject, and the paper by Dennis Kibler and Pat Langley on "Machine Learning as an Experimental Science", in which the authors take a broad look at the goals that underlie the experimental study of learning systems and the types of experiments necessary to achieve them.

Both books will be required reading for those seriously involved in machine-learning research, and will no doubt be frequently cited in the future. Despite its lack of structure, the EWSL volume is the more accessible and perhaps the more valuable collection. But both suffer from the failings of most such volumes — the papers generally lack the broad context necessary to be meaningful to the general reader, or in many cases the researcher in an adjacent part of the field. At a more mundane level, neither book has a subject index, and there are no cumulative lists of references.

These faults may well be unavoidable in books which are put together quickly, so that they can be handed out at a particular conference. But it is surely not asking too much that they should be remedied before the volumes are sold to a wider technical readership. It may seem harsh to criticize the publishers for a sin which is increasingly widespread in the AI world, and doubtless elsewhere. But the lack of some post-conference editing has undoubtedly resulted in two books which are less valuable (if more timely) than they otherwise might have been. □

Max Bramer is Manager of the Knowledge Engineering Programme, Hewlett-Packard Laboratories, Filton Road, Stoke Gifford, Bristol BS12 6QZ, UK, and Chairman of the British Computer Society's Specialist Group on Expert Systems.

Explanation and definition

Alan Isaacs

The Harper Dictionary of Science in Everyday Language. By Herman Schneider and Leo Schneider. *Harper & Row: 1988. Pp. 309. $25.*

The American Heritage Dictionary of Science. Edited by Robert K. Barnhart. *Houghton Mifflin: 1988. Pp. 740. $19.95.*

THESE two books, both called dictionaries of science, are about as dissimilar as any two books claiming to be dictionaries of anything could be. The essential difference is one of the intended audiences.

The title of the Harper book is plain enough, and the blurb tells us that here is "a book that explains scientific terms and techniques with wit and charm and, most of all, in plain English". Although one may find it hard to imagine anyone being either witty or charming in scientific explanation, the Schneiders have been fairly successful in making fairly difficult concepts fairly lucid to fairly intelligent non-scientists. Interferometry, for example, is quite ingeniously explained, so too are computerized axial tomography and boolean algebra. Indeed, there are some extremely good explanations throughout the book, which one could well imagine being helpful to any layman willing to put up with the wit and charm that go with them.

The authors say (in the preface) that their dictionary came into being because a neighbour was confused by standard definitions of entropy — that the only people capable of understanding these definitions would be scientists. So their own entry begins wittily with T.S. Eliot's "This is the way the world ends..." and launches off charmingly into a piece about "the majestic rotation of galaxies". They do not record how their neighbour reacted; one cannot help wondering if he was much the wiser. At least it is clear from the entry — explanation without definition — at whom it is aimed.

Who, though, will use the American Heritage dictionary? On the inside flap of the jacket it is asserted that the book "bridges the gap between the oversimplified and the highly technical reference", while in his preface the editor notes that it is designed to "support" the student. One hopes he means that the biological entries are designed to help the physical scientist, and vice versa? If that is the case, the book could well serve a useful purpose. But a glance at the entry for entropy is not very reassuring if he doesn't mean this. The definition eschews explanation: "a measure of the unavailability of thermal energy for doing mechanical work", a not very helpful quotation from L.K. Runnels, and that is all. Surely, the student of physical science would want something more than that. Some attempt at explanation on the lines of $\Delta S = \Delta Q/T$, at the very least.

Another surprising aspect of Barnhart's book is the treatment of chemistry, which is both inconsistent and out of date. For example, there is no entry for ethanal and that for acetaldehyde does not even refer to this systematic name. There is, however, an entry for ethanol, which is given as an "also called" under ethyl alcohol. Ethene has an entry cross-referring it to ethylene, but the entry at ethylene makes no mention of ethene. In view of the international change from trivial to systematic names, it should be one of the prime tasks for a dictionary at this level to deal correctly with the relationship between the two systems, especially if it is for school and college libraries.

That neither dictionary has solved the problem of either explaining or defining entropy for the layman, the life scientist or the physical scientist, may not be a total condemnation of either. It *is* a hard concept to get across in any depth without mathematics. Moreover, both books contain plenty of other useful explanations (Harper) and definitions (American Heritage). □

Alan Isaacs is Managing Director of Market House Books, Market Square, Aylesbury, Buckinghamshire HP20 1TN, UK. Among other books he is editor of the Macmillan Encyclopedia *and the* Penguin Dictionary of Science.

Cycling essays

Edward Rybicki

Portraits of Viruses: A History of Virology. Edited by F. Fenner and A. Gibbs. *Karger: 1988. Pp.344. SwFr. 147, £66.90, $98.*

SINCE I began teaching virology in 1981, I have come across only one book that purported to be a history of the subject — and that is now sadly out of date. It was pleasing, therefore, to hear that Karger were to bring out the volume under review. My enthusiasm dwindled somewhat when I realized that the book consisted of the 15 "Portraits of Viruses" that have been published in *Intervirology* over the years since 1979, and that I had already read most of them. The essays were written by distinguished and long-serving virologists, and are often as much personal scientific biographies (especially those by Heinz Fraenkel-Conrat on tobacco mosaic virus, and Richard Lister on tobacco rattle virus) as they are contributions to the history of research on a particular group of viruses.

In the preface, the editors say that "this collection of essays has some notable gaps". This is very true: there are no reoviruses here, nor any polyoma- or adenoviruses, and there is only one retrovirus. Worse, the portraits have not been updated or expanded; all of them have been reproduced directly from the journal. The editors say that "for contributions written several years ago, we asked the authors to provide a brief addendum . . .". In fact, only the portraits of the poxviruses (F. Fenner, 1979) and the picornaviruses (J. Melnick, 1983) have such an addendum. The failure to bring the articles up to date is more excusable when their authors have since died — as have Macfarlane Burnet (influenza virus A), Peter Wildy (herpesviruses) and Basil Kassanis (tobacco necrosis virus and its satellite virus) — but it was remiss of the editors not to have insisted that contributors still living should do so.

The most recent essays were published in *Intervirology* in 1986; seven of the others appeared between 1979 and 1981. Thus it is that William Hayes does not include the exciting developments of the past few years, such as the sequencing of lambda and its development as a powerful tool in the recombinant-DNA armoury; Fraenkel-Conrat neglects the sequencing of the tobacco-mosaic-virus genome; in Burnet's essay there is no mention of the cDNA cloning and sequencing of many influenza virus HA and NA genes, nor of the synthetic peptide and monoclonal antibody work on the unveiling of antigen drift; and T. O. Diener does not tell of the elucidation of the replication and self-cleavage mechanisms of viroids. The essays themselves vary from the very personal and relatively sketchy, to the more formal and comprehensive review-type treatments given to poxviruses, picornaviruses and especially to Rous sarcoma virus (J. Svoboda): these have already proved helpful in my teaching, and remain as valuable references; I shall not be referring much to the other chapters.

These points apart, I have no complaints about the "Portraits of Viruses" series. But I do question whether it was necessary to put together this collection, or whether it will be worthwhile (the editors' hopes notwithstanding) to do so again in the future. The series of portraits always was, and remains, at best fragmentary and anecdotal. Publication of the essays in *Intervirology* is sufficient, in my view, to safeguard their authors' contributions to the body of background material which, one hopes, will be used by others for the writing of fuller accounts of the history of virology. □

Edward Rybicki is a Senior Lecturer in the Department of Microbiology, University of Cape Town, PB Rondebosch 7700, South Africa.

Keep Abreast of New Developments in Medicine

Oncology

Z. Tang, M. Wu, Shanghai; **S. Xia,** Wuhan (Eds.)

Primary Liver Cancer

Associate Editor: S. Ye

Foreword by L. Li and F. Qui

1989. 261 figures, 196 tables. Approx. 520 pages. Hard cover DM 460,–.
ISBN 3-540-50228-9
Distribution rights for People's Republic of China: China Academic Publishers, Beijing

Primary liver cancer (PLC) is one of the most frequent malignancies in southeast Asia and ranks third among all malignancies in China. Etiology, epidemiology, pathology, and early diagnosis at a subclinical level are examined by well-known Chinese experts.

UICC: International Union Against Cancer

I. T. Magrath, Bethesda (Ed.)

New Directions in Cancer Treatment

1989. 71 figures. XVIII, 634 pages. Soft cover DM 148,–. ISBN 3-540-19063-5

Contents: New Directions in Cancer Treatment: An Overview. – Physical Approaches to Therapy. – Chemotherapy. – Biological Approaches to Therapy. – Potential Approaches. – Therapeutic Trends in Specific Neoplasms. – Subject Index.

Reproductive Biology

J. Dietl, University of Tübingen (Ed.)

The Mammalian Egg Coat

Structure and Function

Foreword by P. M. Wassarman

1989. 66 figures. XVI, 156 pages. Hard cover DM 126,–. ISBN 3-540-50272-6

The book presents the most up-to-date information concerning the field of gamete interaction in reproductive biology. Especially interesting is the extensive account of the site of synthesis of the extracellular egg coat, which has been a matter of dispute for decades.

M. C. Chapman, J. G. Grudzinskas, T. Chard, London (Eds.)

Implantation

Biological and Clinical Aspects

1988. 74 figures. XII, 258 pages. Hard cover DM 180,–. ISBN 3-540-19533-5

Outlining current research in relation to the establishment of human pregnancy, the areas of endocrinology, protein biochemistry, prostaglandins and immunology are all covered.

Pathology

F. Nogales, University of Granada (Ed.)

Ovarian Pathology

1989. 62 figures, some in color. Approx. 180 pages. (Current Topics in Pathology, Volume 78). Hard cover DM 148,–.
ISBN 3-540-50217-3

Great emphasis in this up-to-date text is placed on problems arising from surgical-pathological staging of ovarian tumours, such as the integrative role of the oncologist-pathologist team. Two subjects which are seldom reviewed in the literature – hormonally related non-neoplastic conditions and the ovary in infertility – are given separate chapters.

H. Rotterdam, New York University Medical Center; **H. T. Enterline,** University of Pennsylvania

Pathology of the Stomach and Duodenum

1989. 220 figures. VII, 320 pages. Hard cover DM 248,–. ISBN 3-540-96823-7

Contents: Embryology, Anatomy and Histology. – Physiology. – Anomalies. – Gastritis. – Peptic Ulcer. – Hyperplasias and Benign Epithelial Tumors. – Carcinoma of the Stomach. – Carcinoma of the Duodenum. – Carcinoid (Neuroendocrine) Tumors. – Pseudolymphoma and Lymphoma. – Mesenchymal Tumors. – Miscellaneous Lesions.

Physiology

Reviews of Physiology, Biochemistry and Pharmacology

Editors: M. P. Blaustein, H. Grunicke, E. Habermann, H. Neurath, S. Numa, D. Pette, B. Sakmann, U. Trendelenburg, K. J. Ullrich

Volume 111

1988. 32 figures. VI, 231 pages. Hard cover DM 128,–. ISBN 3-540-19156-9

Contents: *A. Philippou:* Regulation of Blood Pressure by Central Neurotransmitters and Neuropeptides. – *J. H. Exton:* The Roles of Calcium and Phosphoinositides in the Mechanisms of α_1-Adrenergic and Other Agonists.

Progress in Sensory Physiology

Editors.: H. Autrum, D. Ottoson, E. R. Perl, R. F. Schmidt, H. Shimazu, W. D. Willis

Editor-in-Chief: D. Ottoson

Volume 9

1989. 71 figures. Approx. 240 pages. Hard cover DM 160,–. ISBN 3-540-50282-3

Contents: *R. D. Foreman:* Organization of the Spinothalamic Tract as a Relay for Cardiopulmonary Sympathetic Afferent Fiber Activity. – *G. N. Akoev, G. N. Andrianov:* Synaptic Transmission in the Mechano- and Electroreceptors of the Acousticolateral System. – *J. Syka:* Experimental Models of Sensorineural Hearing Loss – Effects of Noise and Ototoxic Drugs on Hearing. – *Y. Oomura:* Sensing of Endogenous Chemicals in Control of Feeding. – *J. E. Sánchez-Criado, O. A. Mora, A. Gallego:* Structure and Function of the Vomeronasal System – The Vomeronasal Organ as a Priming Pheromone Receptor in Mammals. – Subject Index.

NEW TITLES FROM IRL PRESS

New Spiralbound Format

THE PRACTICAL APPROACH SERIES

Starting with *Genome Analysis*, edited by Kay Davies, each *Practical Approach* title will be available in a new, hardcover, spiralbound format in addition to the paperback version.
Written specifically for laboratory use, these sought-after manuals will now lie flat on your work surface allowing even easier access to the latest protocols.

GENOME ANALYSIS: A PRACTICAL APPROACH

Edited by K E Davies

Includes:
Techniques for mammalian genome transfer; genome mapping by restriction fingerprinting; pulsed field gel electrophoresis and the technology of large DNA molecules; chromosome jumping; the polymerase chain reaction; DNA fingerprinting; mapping complex genetic traits in humans

1 85221 129 6, 290 pp, spiralbound, £27.00
1 85221 110 5, paperback, £18.00, 1988

PLANT MOLECULAR BIOLOGY: A PRACTICAL APPROACH

Edited by C H Shaw

Includes:
Analysis of plant gene expression and structure; isolation and analysis of chloroplasts and plant mitochondria; subcellular localization of macromolecules using microscopy; foreign gene expression in plants; protoplast isolation and transformation; transposable elements and gene-tagging

1 85221 057 5, 324 pp, spiralbound, £29.00
1 85221 056 7, paperback, £19.00, 1988

ANTIBODIES VOLUME II: A PRACTICAL APPROACH

Edited by D Catty

Includes:
Antibodies in blood group serology; antibodies in HLA serology; immunoassay using radiolabels; ELISA and related enzyme immunoassays; immunoperoxidase methods; fluorescence activated cell sorting; antibodies for tumour immunodetection

0 19963 018 6, 290 pp, hardback, £29.00
0 19963 019 4, paperback, £19.50, January 1989
(*note – not available as spiralbound*)
Volumes I and II also available as a set:
0 19963 063 1, paperback, £32.50, February 1989

HPLC OF MACROMOLECULES: A PRACTICAL APPROACH

Edited by R W A Oliver

Includes:
Columns for HPLC separation of macromolecules; HPLC instrumentation; size-exclusion HPLC of proteins; reversed-phase chromatography of proteins; high performance affinity chromatography; HPLC of oligonucleotides; affinity chromatography of complex carbohydrates using lectins

0 19663 020 8, 254 pp, spiralbound, £27.00
0 19663 021 6, paperback, £18.00, February 1989

LIGHT MICROSCOPY: A PRACTICAL APPROACH

Edited by A J Lacey

Includes:
Principles and aims of light microscopy; making transparent specimens visible by inducing contrast; image recording; immunohistochemistry; histochemistry and the light microscope; fluorescence microscopy; micrometry and image analysis; video microscopy; chromosome banding

0 19663 036 4, 320 pp, spiralbound, £29.00
0 19663 037 2, paperback, £19.00, February 1989

PROTEIN STRUCTURE: A PRACTICAL APPROACH

Edited by T E Creighton

Includes:
SDS gel electrophoresis; isoelectric focusing; two-dimensional PAGE; immunological detection; peptide mapping; disulphide bonds; minimizing irreversible modification; predictions from gene and amino acid sequences; spectral methods; immunochemical analysis; folding proteins; measuring conformational stability

0 19663 000 3, 370 pp, spiralbound, £30.00
0 19663 001 1, paperback, £20.00, January 1989

PROTEIN FUNCTION: A PRACTICAL APPROACH

Edited by T E Creighton

Includes:
Maintaining protein function; ligand-protein binding affinities; ligand blotting; affinity labelling; cross-linking by disulphide bonds; competitive labelling; analysis, identification and purification of sequence specific DNA-binding proteins; chemical modification; site-directed mutagenesis; determining roles of subunits

0 19963 006 2, 320 pp, spiralbound, £29.00
0 19963 007 0, paperback, £19.00, March 1989
Also available as a set (with *Protein Structure*):
0 19963 065 8, paperback, £33.00, March 1989

CELL GROWTH AND DIVISION: A PRACTICAL APPROACH

Edited by R Baserga

Includes:
Measuring parameters of growth; mouse embryo cells; C3H 10T½ and NIH3T3 cell lines; human leukemia cells; normal human epidermal keratinocytes and mesothelial cells; cloned T cell proliferation; muscle cell cultures; human diploid fibroblasts; cell synchronization; BALB/C-3T3 cells

0 19963 026 7, 210 pp, spiralbound, £27.00
0 19963 027 5, paperback, £18.00, March 1989

PROTEIN SEQUENCING: A PRACTICAL APPROACH

Edited by J B C Findlay and M J Geisow

Includes:
Protein and peptide purification; peptide preparation and characterization; automated solid-phase microsequencing; gas or pulsed-liquid phase sequence analysis; sequencing by mass spectrometry; manual methods of protein sequencing; structure prediction

0 19963 012 7, 250 pp, spiralbound, £27.00
0 19963 013 5, paperback, £18.00, March 1989

COMPUTERS IN MICROBIOLOGY: A PRACTICAL APPROACH

Edited by T N Bryant and J W T Wimpenny

Includes:
Computers in taxonomy and systematics; data analysis packages; computers in fermentation; modelling; simulation; image analysis in microbiology; computers in clinical microbiology; computers in teaching microbiology

0 19963 014 3, 264 pp, spiralbound, £27.00
0 19963 015 1, paperback, £18.00, March 1989

ON CELL AND MOLECULAR BIOLOGY

IN FOCUS

In Focus is a new series of textbooks offering the very latest information on fast-moving areas of biochemical and immunological research. Each book, written specifically for undergraduate and graduate students, is an up-to-date review of a high-interest topic, supplementing both lecture course and practical work.

'All are strongly recommended, providing a missing link in scientific publications.'
Times Higher Education Supplement (on *Complement*, *Immune Recognition*, and *Lymphokines*)

COMPLEMENT: IN FOCUS

S K A Law and K B M Reid
'This is a gem of a book: a pleasure to read and a must for the molecular immunologist's bookshelf.' **Trends in Biochemical Sciences**
1 85221 061 3, 82 pp, paperback, £5.95, 1988

LYMPHOKINES: IN FOCUS

A S Hamblin
'Lucid, well-organized and interesting . . . the use of explanatory diagrams and summary tables is most welcome, the latter factor ensuring the worth of the book as a reference volume.' **Trends in Biochemical Sciences**
1 85221 055 9, 82 pp, paperback, £5.95, 1988

IMMUNE RECOGNITION: IN FOCUS

M J Owen and J R Lamb
1 85221 062 1, 84 pp, paperback, £5.95, 1988

ENZYME KINETICS: IN FOCUS

A Cornish-Bowden and C W Wharton
'This textbook . . . is good, and is particularly helpful for its brevity and wisdom.' **Trends in Biochemical Sciences**
1 85221 074 5, 86 pp, paperback, £5.95, 1988

ANTIGEN PRESENTING CELLS: IN FOCUS

J M Austyn
0 19963 005 4, 80 pp, paperback, £5.95, April 1989

GENE STRUCTURE AND TRANSCRIPTION: IN FOCUS

T Beebee and J Burke
1 85221 014 1, 80 pp, paperback, £5.95, 1988

GENETIC ENGINEERING: IN FOCUS

J Williams and R K Patient
1 85221 071 0, 80 pp, paperback, £5.95, 1988

MOLECULAR BASIS OF INHERITED DISEASE: IN FOCUS

K E Davies and A P Read
1 85221 073 7, 80 pp, paperback, £5.95, 1988

MEMBRANE STRUCTURE AND FUNCTION: IN FOCUS

W H Evans and J M Graham
1 85221 099 0, 80 pp, paperback, £5.95, April 1989

REGULATION OF ENZYME ACTIVITY: IN FOCUS

J H Ottaway
1 85221 072 9, 86 pp, paperback, £5.95, 1988

FRONTIERS IN MOLECULAR BIOLOGY

Frontiers in Molecular Biology is a major and completely up-to-date research review series designed to cover fast-breaking areas of molecular biology research.

MOLECULAR IMMUNOLOGY: FRONTIERS IN MOLECULAR BIOLOGY

Edited by B D Hames and D M Glover
'The text is certainly to be highly recommended for the advanced student of immunology or researchers in related areas who wish to update their knowledge . . . a veritable sourcebook of recent experimental data.' **Cell**
1 85221 079 6, 260 pp, hardback, £23.00
1 85221 075 3, paperback, £15.00, 1988

TRANSCRIPTION AND SPLICING: FRONTIERS IN MOLECULAR BIOLOGY

Edited by B D Hames and D M Glover
Includes:
Trans-acting protein factors and the regulation of eukaryotic transcription; enhancers and other *cis*-acting regulatory sequences; termination and 3′ end processing of eukaryotic RNA; RNA splicing
1 85221 080 X, 210 pp, hardback, £23.00
1 85221 076 1, paperback, £15.00, 1988

Essential information for all active in bioengineering and biotechnology...

Genetic Engineering and Biotechnology Yearbook

NORTH AMERICA and JAPAN EDITION 1988/89

edited by **Alan G. Walton,** *Oxford Partners, Stamford, CT, and* **S.K. Hammer,** *President, "Verbatim", Tarrytown, NY, USA*

Here is the latest edition of *"the definitive source for company information in this rapidly expanding field."* (New Technical Books). The new edition comes in two separate volumes and features:

- **a new, easy-to-use format**
- **in-depth corporate profiles of more than 300 US companies whose primary business, research and products involve genetic engineering**
- **550 other US companies with genetic engineering activities**
- **a *completely new* directory of 300 venture capital companies with interests in biotechnology**
- **over 200 Japanese company profiles**
- **over 100 Canadian company profiles**
- **A Fields of Focus product index (in chart form) for 'at-a-glance' identification of fields of interest of each company**
- **comprehensive cross-index of companies to enable easy tracing of the numerous, often complex, intercompany links.**

Each company profile includes the company's name, address, phone number, contact person and, in most cases, the business history, structure, ownership/ management, research update, status and availability of products, and financial information. The new **Yearbook** is a MUST for venture capital companies, large industrial coporations and anyone with an investment interest in genetic engineering.

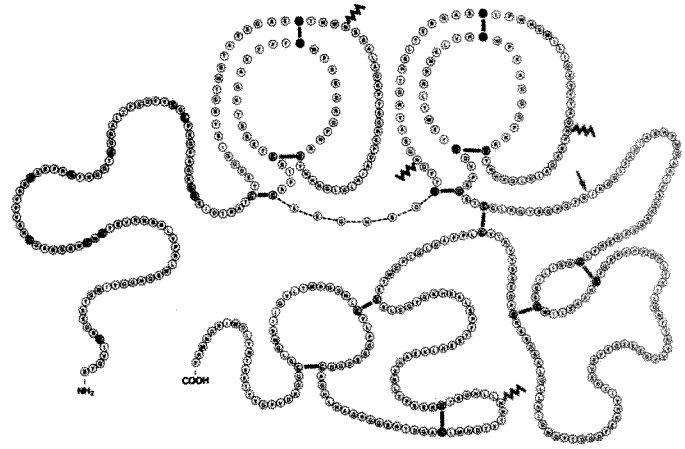
Claims on tissue plasminogen activator

R. Stephen Crespi

A 'master' patent on a recombinant protein product has twice been overturned in British courts. The consequences may be far-reaching.

THE struggle between Genentech and the Wellcome Foundation over Genentech's British patent for tissue plasminogen activator is of keen interest world-wide. Tissue plasminogen activator (TPA) converts plasminogen into plasmin, the enzyme that breaks down fibrin clots formed in coronary thrombosis, and has a large potential market. Britain is the arena for the first patent litigation on this biotechnology product, but the issues at stake transcend national boundaries and the judgement of the British courts will have international influence.

The patent in suit was obtained through the British system, but Genentech also has a parallel patent application in the European Patent Office, which will probably be granted no later than mid-1989. Depending on the claims that issue, the European patent will give Genentech an apparent second chance to protect its British market if the British national patent, which was rejected in July 1987 in the British Patents Court and again by the Court of Appeal in October 1988, is finally held invalid on appeal to the House of Lords. At the time of writing Genentech has yet to appeal.



Genentech has a corresponding patent in the United States, which was granted in August 1988. This claims the DNA sequence that encodes TPA as well as expression vectors and transformed microorganisms containing this gene, but not the final TPA product. Litigation on the US patent has also begun.

The significance of the TPA case in Britain is that Genentech is strenuously pursuing patent claims for the recombinant protein product as such, and for correspondingly broad processes, rather than a claim for any detailed method limited to particular plasmids chosen to carry the TPA cDNA into the particular host cells used by Genentech to express the protein product. The case is therefore a prototype for other patents in the pipeline covering other blood proteins — including factor VIII, antithrombin and serum albumin — and may well be a pointer to the evaluation of the patent system in relation to similar biotechnology products. It is not surprising, in view of the decisions handed down so far, that some commentators have suggested devising another type of legal protection that would recognize with more certainty the achievements of those who are first to succeed in producing valuable proteins by genetic engineering.

To appreciate the issues in the TPA case, it is necessary to understand how patents are constructed. A patent specification consists of two parts: first, the technical description, which sets out the nature of the invention and instructs the skilled worker how to reproduce it; second, the legal definitions, known as the 'claims', which circumscribe the protection given by the patent. The claims are verbal formulae defining the protected technology in terms of process, product, use or some other category. Here the wording is important, although the courts have always allowed some elasticity of interpretation in order to catch clever evaders of the literal text. The European Patent Convention tries to strike a balance between the extremes of tight literal wording, on the one hand, and woolly statements of uncertain scope on the other.

A claim to the product itself (a *per se* claim) is possible when the product is new (that is, it has not been previously described). But where the product is not new *per se*, but only the process for making it is new, it is possible to claim the product as made by the particular process (a product-by-process claim). As human TPA was not a totally new substance at the priority date of Genentech's first patent application (in the United States), it was appropriate to use the more restricted product claim, as exemplified by claim 3 in the TPA patent, which reads: "Human tissue plasminogen activator as produced by recombinant DNA technology".

Patent disputes centre almost entirely upon the claims. The patentability conditions of novelty, inventiveness and industrial application or utility are applied solely to the claimed subject matter. The other main condition is that the inventor must provide a sufficient or 'enabling' disclosure. The disclosure requirement applies to the technical description; and if a claim is so broad as to cover subject matter for which the directions given to make the product or perform the process are seriously defective, the patent will be invalid.

Desirable form — diagram of the potential structure of human TPA, published by Pennica et al. *after the priority date of Genentech's first patent application (*Nature *301, 219; 1983).*

Here, I should dispose of a common misunderstanding. It is incorrect to assume that products of nature cannot be patented on the grounds that, by reason of their previous existence in nature, they cannot be novel. Patent law has become much more liberal on this point by taking into account the merit of first discovery of a natural substance, its isolation and provision of a product in a form useful for therapeutic or other purposes. The guidelines of the European Patent Office follow this approach and endorse the patentability of natural products in the proper circumstances. Of course, TPA had been isolated from human tissue before Genentech began work, and the identical product had also been produced by culture of the Bowes melanoma cell line. The TPA claim quoted above was therefore appropriate. As defined, the product is not one of nature but of a non-natural process.

Genentech based its case on the position stated in the patent itself:

The present invention arises in part from the discovery of the DNA sequence and deduced amino acid sequence of human plasminogen activator. This discovery enabled the production of human plasminogen activator via the application of recombinant DNA technology, in turn, enabling the production of sufficient quality and quantity of material to initiate and conduct animal and clinical testing as prerequisites to market approval, unimpeded by the restrictions necessarily inherent in the isolation methods hitherto employed involving production and extraction from existing cell culture. This invention is directed to these associated embodiments in all respects.

The Patents Court held that broad product claims such as claim 3 would only have been acceptable if the patentee had been the first to discover TPA or its desirable properties. Although Genentech had been the first to identify the DNA-coding sequence and to deduce the amino-acid sequence of the protein (in the court said to be "a remarkable job of work" which "involved laborious and costly effort") it had already been recognized by other workers as desirable to produce TPA in quantity by recombinant DNA methods. Genentech's product claims were therefore too wide in being directed to a possible and obviously desirable end that could be reached by routes on which only limited guidance had been given. Only a limited process claim could be upheld in these circumstances.

Last October, at least four crucial questions emerged in the Court of Appeal. What precisely did Genentech *invent* (rather than merely *discover*)? What scope of claim would properly reflect the invention? Was the claim to recombinant TPA obvious to the skilled worker at the relevant date? And what level of skill and knowledge would the hypothetical ordinary skilled worker be assumed to have in relation to the previous question?

Key contribution?

Genentech stuck to the assertion that the discovery of the sequence was the key contribution, the 'one log holding up the log jam' in the way of progress to the desired product. But both British and European law state that a discovery, as such, is not patentable, and it is universal law that you cannot patent knowledge itself but only its practical application. One judge floated the idea of subtracting the discovery element and seeing whether what was left amounted to an inventive step. This is a dangerous line to follow for any invention in the natural sciences, and fortunately the final judgement will not rest on this type of analysis.

On scope of claim, Genentech pursued a very bold line. The company argued that the discovery of the cDNA sequence led not only to the production of the recombinant form of natural TPA having the amino-acid sequence 1 to 527 shown in Fig. 5 of the patent drawings, but also opened the way to modifications of the natural molecule (for example, by site-directed mutagenesis of the underlying DNA) which preserved the essential TPA-type activity. This extension of the claim was of no great importance as regards Wellcome's intended product, but shows that Genentech was seeking to dominate a wide range of second- and subsequent-generation products in this field. To claim for the TPA patent the status of a master patent on the basis of discovering the sequence of TPA alone was remarkably daring. The Court of Appeal found this far-reaching proposal unacceptable and was not prepared to sustain claim 3 even if limited to the recombinant equivalent of the natural product. Thus, one judge pronounced: the "contention that Genentech should be protected against any use of this information howsoever this may be achieved in the future is . . . not a claim to a method embracing the discovery but rather a claim for protection of the discovery as such".

In patent disputes over new chemical compounds, it has been argued that something is obvious if a number of research groups are working along similar lines. This argument has not been well received. In the TPA case, however, it succeeded, as seen in the following extracts from the judgement:

It is agreed between the experts that at the relevant time, in early May 1982, the production of quantities of TPA adequate to treat human patients suffering from blood clots was known to be a desirable objective and it is further agreed that the Bowes melanoma cell-line was then available and was known to be a source of TPA and of the corresponding mRNA. It was of course then known that the nucleotide and amino-acid sequences of TPA existed, though their composition was not known. All the steps taken by Genentech in finding out the composition of the sequences and applying that knowledge to produce human TPA, as defined in the specification, by recombinant DNA technology were applications of known technology, and no step was by itself inventive. . . .

. . . it was indeed obvious, in my judgement, to the person skilled in the art to set out to produce human TPA by recombinant DNA technology. At least four teams did just that at about the same time. The evidence of those at Leuven and Umea [other research groups] as to their choice of projects is particularly relevant. The end was a known desideratum, and to proceed by oligonucleotide probing was, if not the first choice of each team, an early choice which lay in the way, ready to hand.

Wellcome thus persuaded two of the three judges in the Court of Appeal that the product claims were invalid not only because they were conceptually obvious but also because their practical realization involved no inventive step. Wellcome did not fare so well with the additional contention that the claims were also of unfairly wide scope in light of the technical description. This is a matter that the Patent Office can raise when it examines a patent application. But once a patent has been granted, the Court of Appeal held that it cannot be re-opened under the permitted grounds on which patents can be revoked. This conclusion stands in sharp contrast to the long-standing tradition in British patent law that the courts can also consider the question of fairness of the scope of a claim in the light of the patent description. If Wellcome counter-appeals against this point, the House of Lords must decide whether the 1977 Patents Act denies to the courts a remedy open to the lowest level of authority in the British patent system.

New problem

What then is unique or new about the TPA case? One Appeal judge said:

. . . we are here dealing with a new problem. New not only because the technology is very recent, but also because the problems arising from the manufacture of an existing substance with known properties, by the application of a known technology, through the medium of a new discovery and novel intermediate artifacts (the vectors) has never (so far as I can see) been considered by the courts.

The final answer, however, has been clear and unanimous from all judges in the case, even though their individual approaches vary distinctly. The same judge also said:

. . . the importance of the present action far outstrips the ultimate decision itself, for it is impossible to arrive at a decision without expressing conclusions which apply to this fledgling industry as a whole, and which (if reflected in courts elsewhere in the European Community and outside) may have an important bearing on its future.

However hard the judgements may seem, they simply result from the application of standard principles of patent law to the cloning of DNA that encodes naturally occurring proteins. For some time it has been an open question whether such cloning involves invention as distinct from experimental skill and the application of sufficient resources. But it is difficult to see how a different legal system would cope better with the situation. Copyright as an alternative to patent law is a blind alley in relation to DNA sequences, and no other new system is yet on any lawyer's drawing board. Moreover, the difficulties are not nearly as great for newly isolated natural proteins and the products of protein engineering; here the question of inventiveness will return to the more familiar field of new compound chemistry. Given that the complexities of the Genentech case stem from transitional problems, it is premature to despair of the patent system for the protection of innovation in biotechnology. □

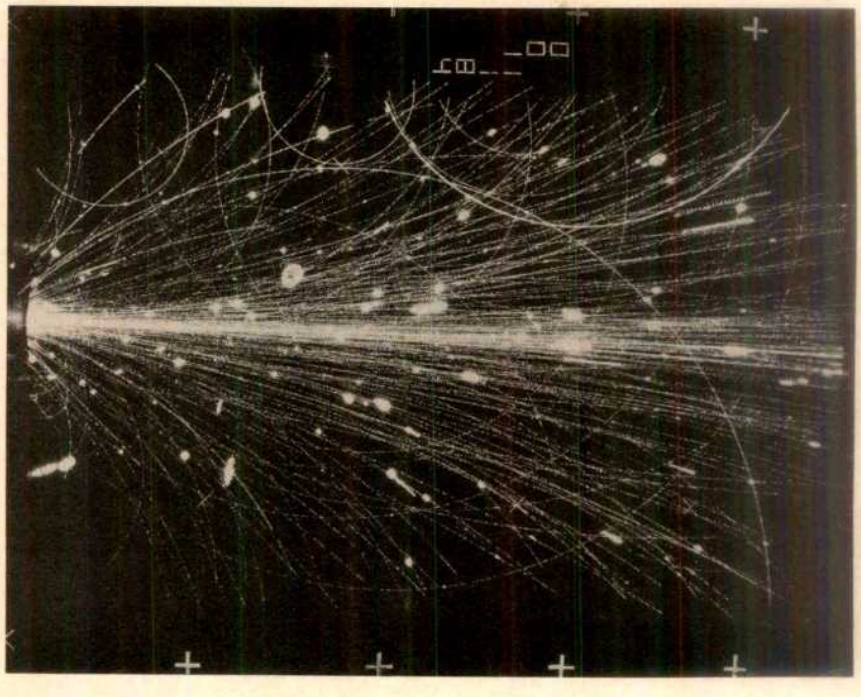
The physics of dense nuclear matter from supernovae to quark gluon plasma

Reinhard Stock



Physics Department, University of Frankfurt, D-6000 Frankfurt, FRG

At high density, nuclear matter is better regarded as a dense fluid rather than a collection of individual protons and neutrons. A good understanding of the properties of nuclear matter, important in the physics of neutron stars and the Big Bang as well as heavy atomic nuclei, is now emerging.

IN light atomic nuclei, the constituent protons and neutrons retain some of their individual identity and occupy distinct energy states, but in the interior of heavy nuclei, where the density is higher, the available energy states are closer together and more numerous, and the neutrons and protons form a continuous, fluid-like medium known as nuclear matter. Ground-state nuclear matter is stable because the powerful attractive and repulsive components of the strong interaction nearly cancel out. The additional electromagnetic interaction—Coulomb repulsion between the charged protons—causes a stability limit at nucleon number $A \approx 210$, close to that of lead and bismuth. Were it not for this interaction, nuclear matter could form stable volumes of any microscopic or macroscopic size. Stability returns only when the atomic number becomes very large, $A \gtrsim 10^{57}$. Then gravitational attraction is enough to balance the repulsion of the strong interaction, permitting the formation of neutron stars.

Despite decades of research in nuclear physics, we still do not understand nuclear matter very well. Until recently, the physicists' task was seen largely as the construction of detailed models for isolated nuclear species and their excited states, and for the interactions between them. Nuclear matter was regarded as an abstract extrapolation from studies of nuclear structure. This attitude changed about 20 years ago, when astrophysicists began to develop semi-quantitative models for supernova dynamics, neutron stars and the evolution of the Big Bang, all of which demanded detailed understanding of the continuum properties of extended nuclear matter or, more generally, of strongly interacting matter at high density. This need prompted the research described here.

The ground-state density in nuclei is 2.7×10^{14} g cm^{-3}, corresponding to a numerical nucleon density of $\rho_0 = 0.15$ fm^{-3} ($1\ \text{fm} = 10^{-15}$ m) and an energy density $\varepsilon_0 = 0.14$ GeV fm^{-3}. Familiar nuclear reactions such as fission, fusion and alpha-decay proceed with only small changes in density, of a few per cent: nuclear matter flows gently between its various 'droplet' species. Type II supernovae (that is, those occurring among young, massive (Population I) stars) may, on the other hand, reach densities of about $4\rho_0$, and still higher densities are proposed for the interior of heavy neutron stars. To understand supernova dynamics, the stability and static architecture of neutron stars, and the critical limits governing black-hole formation, we need to know the macroscopic properties of nuclear matter, such as compressibility, specific heat and entropy density. In short, we need to know the equation of state of nuclear matter (the relationship between pressure, density and

A streamer-chamber photograph of a central collision between ^{16}O and Pb at the CERN SPS, with an energy of 200 GeV per nucleon. It illustrates the high multiplicity of final-state events which must be scrutinized for evidence of the transient formation of quark matter during the collision. The magnetic field in the detector separates positive and negative particles, bending them according to their momenta, and track brilliance measurements distinguish particle types. The tracks in the pencil surrounding the beam axis,corresponding to the forward part of the phase space, cannot be resolved, but are of minor significance in the analysis.

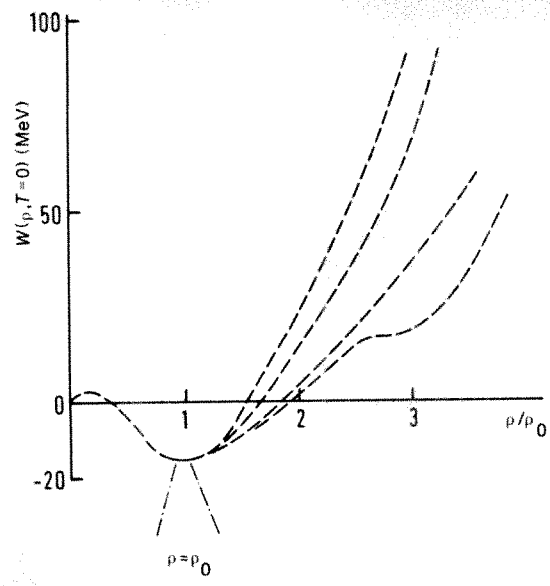


Fig. 1 Sketch of the energy-density function (the energy per particle) of nuclear matter. The internal energy per nucleon of cold ($T = 0$) matter has a well-known minimum at density $\rho = \rho_0$, corresponding to the matter inside stable nuclei. Towards higher densities the energy should increase.

temperature) over a wide range of density, far beyond that of the nuclear interior.

History

The work described in this article had the goal of achieving high compression of nuclear matter in the laboratory by colliding heavy nuclear projectiles 'head-on' at relativistic energy. The concept of shock compression in such heavy-ion collisions was analysed theoretically between 1973 and 1975 by H.A. Bethe at Cornell, G. Chapline at Lawrence Livermore Laboratory, W. Greiner at Frankfurt and their collaborators[1-3]. At the same time, experimental investigations were made possible by construction of the Bevalac accelerator at Lawrence Berkeley Laboratory (LBL). By combining a low-energy heavy-ion linear accelerator with the old high-energy proton synchrotron (Bevatron) the Bevalac first provided beams of nuclei up to $A = 40$ (calcium) at energies up to 2 GeV per projectile nucleon. With a total kinetic energy about twice the rest-mass of the nucleus, the projectiles move at relativistic velocity ($v \approx 0.9c$). Technical improvements circumvented the limitation to $A \leq 40$, permitting beams of gold and uranium nuclei to be produced. Similar work at Dubna, Soviet Union, reached higher energy (3.5 GeV per nucleon) but only for nuclei up to $A = 20$ (neon), adding an element of competition to the emerging field of relativistic heavy-ion physics.

At Berkeley, the search for the nuclear equation of state was carried out, in particular, by three major international collaborations of physicists with backgrounds in both nuclear and particle physics. A collaboration between Japan and the United States focused on the development of magnetic spectrometers, and two German-US groups constructed complementary types of 4π-detector systems, the visual-track-recording streamer chamber[4] and the electronic Plastic Ball detector[5], which simultaneously measure all particles created in a collision event. By the early 1980s, the German-US collaboration had succeeded in an initial demonstration of the shock-compression mechanism and arrived at a first semi-empirical estimate of the equation of state in the density domain $1.5 < \rho/\rho_0 < 3.5$ (refs 4, 5). But a different conclusion was reached at about the same time from the dynamical model for the so-called prompt supernova-bounce mechanism[6], which indicated an ultra-soft (very low compression energy) equation of state. This was in strong disagreement with the very stiff (high compression energy) equation of state indicated by the results from heavy-ion collisions. Subsequent theoretical work has arrived at a possible reconciliation of the two results. A new generation of refined experimental inverstigations, both at LBL and with the synchrotron-storage ring combination which is now under construction at GSI Darmstadt, will be based on these ideas.

Experiments in the GeV-per-nucleon energy domain move far away from familiar ground-state nuclear matter but do not reach the very limit of dense matter consisting of hadrons (nucleons, baryon resonances, pions, kaons and so on). The gauge theory of the strong interaction, quantum chromodynamics (QCD), leads one to expect a phase transition at a high hadronic packing density, in which the quarks and gluons escape from of their confinement within hadron 'bags' and move instead through an extended quark-gluon medium termed quark matter[7]. A modern statistical method used to obtain the QCD equation of state, lattice-gauge QCD, has predicted that this phase transition from hadronic to quark matter should occur at energy densities of $\varepsilon \approx 2$-3 GeV fm^{-3}, about 20 times the ground-state nuclear-matter energy density[8]. The Bevalac and future similar accelerators do not reach beyond ~ 0.7 GeV fm^{-3}.

The quark-gluon plasma is a primordial medium whose properties are dictated by the strong force between quarks. It probably existed during the first microsecond (the quark era) of the Big Bang, just before the 'freezeout' into recognizable hadrons. Demonstration of its existence and determination of its critical density, temperature and transition enthalpy would not only provide a novel check for QCD but would also aid our understanding of the composition and distribution of matter in the hadronic period of the Universe, which still exists today. Far higher accelerator energies are required to probe this state. A programme of heavy-ion reaction studies was thus begun at the Alternating Gradient Synchrotron (AGS) at Brookhaven National Laboratory, and at the Super Proton Synchrotron (SPS) at CERN, Geneva. Both have beams of $A \approx 30$ (^{28}Si, ^{32}S), the AGS reaching 14.5 GeV per nucleon, the SPS up to 200 GeV per nucleon. In first runs during 1986-87, new international experimental collaborations have employed vastly more complicated and diverse instruments than earlier studies at the Bevalac and in Dubna. The first results seem to indicate that energy densities of 2-3 GeV fm^{-3} are indeed attained and some initial observations are briefly described at the end of this article.

The nuclear equation of state

The mechanics of continuous media are described in the equation of state, which specifies the pressure as a function of density and temperature, $P(\rho, T)$. For microscopic models, the energy per particle, $W(\rho, T)$ is a more convenient quantity. Knowledge of W is, in principle, equivalent to knowing the equation of state, because

$$P(\rho, T) = \rho^2 \frac{\partial W(\rho, T)}{\partial \rho} \quad \text{(at constant entropy)} \qquad (1$$

and the term equation of state is often loosely employed for the function $W(\rho, T)$. In the absence of thermal excitation, that is for $T = 0$ states such as nuclear ground states or neutron-sta

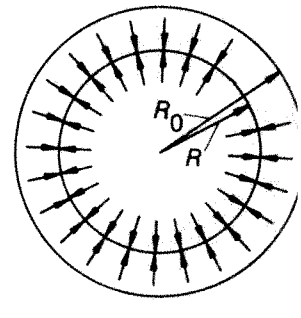

Fig. 2 Sketch of hydrostatic equilibrium in a neutron star of radius R_0. At each subshell with radius R the compressional nuclear matter pressure has to counterbalance the gravitational inward pressure of the layer from R to R_0.

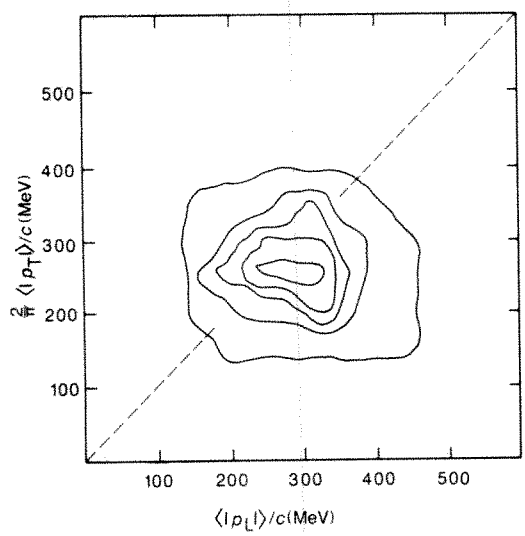

Fig. 3 The achievement of a temporary thermal equilibrium in nucleus-nucleus collisions requires that the momentum of the resultant body in the mean transverse ($\langle|p_T|\rangle$) and longitudinal ($\langle|p_L|\rangle$) directions are equal. The data for collisions of ^{40}Ar and Pb at 0.8 GeV per nucleon demonstrate that this is fulfilled on average: the contour lines of event frequency (each spaced by a factor of two) show a 'mountain' at the diagonal.

matter, it is sufficient to know the compressional energy $W(\rho, T=0)$, from which the $T=0$ equation of state follows:

$$P(\rho, T=0) = \rho^2 \frac{\mathrm{d}W(\rho, T=0)}{d\rho} \qquad (2)$$

Figure 1 illustrates the qualitative expectations for $W(\rho, T=0)$ of nuclear matter. The minimum at $\rho = \rho_0$ represents the stability of ground-state matter: $P(\rho_0, T=0) = 0$ from equation (2). $W(\rho_0, T=0)$ is the familiar mean binding energy per nucleon, W_0, given by the Bethe-Weizsäcker formula. The assumption of a linear response to perturbations about $\rho = \rho_0$ yields

$$W(\rho, T=0) = \frac{K}{18\rho_0^2}(\rho - \rho_0)^2 + W_0 \qquad (3)$$

$P(\rho)$ then crosses the $P=0$ axis with slope $(\mathrm{d}P/\mathrm{d}\rho)_{P=0} = K/9$, and the stiffness of the medium is given by the compressibility K, which also fixes the sound velocity. An estimate of K can be obtained from the excitation energy of the nuclear monopole vibrational state, which has been successfully described as a collective density oscillation about ρ_0. The canonical semi-empirical value thus derived was previously considered to be $K = 220 \pm 30$ MeV (ref. 9) but new data and theory now indicate $K = 300 \pm 25$ MeV (ref. 10), a compression response which must be considered 'stiff'; a 'soft' response corresponds to $K \approx 150$ MeV.

So what is there left to do? Figure 1 shows that there are vastly different possible forms for W at $\rho > 1.5\rho_0$. The monopole vibration covers only a tiny density interval, $\rho = \rho_0 \pm 2\%$, in which it confirms the parabolic shape (equation 3) and yields a value for the constant K. W cannot remain parabolic at high ρ/ρ_0 because nuclear matter would behave acausally (sound speed $v_s > c$) even at neutron-star densities. The parameter K alone does not describe $W(\rho, T=0)$ and may be totally irrelevant for $\rho > 2\rho_0$. In this domain W should of course grow with ρ because the short-range nuclear interaction is repulsive. This can be understood qualitatively by observing that the average distance r of neighbouring nucleons is about 1.8 fm in ground-state, $\rho = \rho_0$ matter, which is just twice the nucleon 'radius' $R = 0.9$ fm found from electron scattering[11]. At $\rho = \rho_0$, the nucleons are thus already tightly packed, and at fourfold compression they would get squeezed to $r \approx 1.1$ fm, so that their internal quark wavefunctions would overlap significantly. The Pauli principle would then force some of the quarks up to orbits of higher energy and this, crudely speaking, is the energy expended during compression. W thus grows with ρ—but how steeply?

Consider neutron stars, for example. Figure 2 illustrates the relevance of the equation of state for radial density distribution and stability. Hydrostatic equilibrium demands that the inward gravitational pressure is compensated by an equally large outward pressure from nuclear-matter incompressiblity, at each radial shell of thickness $R_0 - R$ (where R_0 is the radius of the star). $P(\rho, T=0)$ thus determines the stellar density distribution $\rho(R)$. If the total mass is too high or the equation of state is too soft at high ρ, there is no stable solution and gravitation creates a black hole. If the strong interaction could be removed, the Fermi energy of the degenerate neutron gas alone would let $W(\rho, T=0)$ increase as $\rho^{2/3}$, and the maximum mass would be the well-known Chandrasekhar limit of 1.4 solar masses ($M_\odot$) (refs 12, 13). But neutron stars of up to 2 $M_\odot$ are known[14], so the strong interaction must add to the repulsion. For $\rho \gtrsim 2\rho_0$, $W(\rho)$ thus grows faster than $\rho^{2/3}$ but slower than ρ^2.

Shock compression in relativistic collisions

Shock compression occurs when portions of a medium move through each other at supersonic velocities. If two equal-mass heavy nuclei collide head on at a beam energy of 1 GeV per nucleon, the interpenetration velocity of the target and projectile nuclear matter in the centre-of-mass frame is about $0.7c$, well above the velocity of sound or of any other mechanism that could transport energy or matter out of the reaction volume. Matter and energy therefore pile up in the shock zone, producing the desired compression in a 'fireball' volume. The hydrodynamical model of shock formation[1-3] predicts a fireball density of $\rho \approx 3\rho_0$ at this energy, a temperature[15] of about 80 MeV ($\sim 10^{12}$ K) and a lifetime of $\sim 5 \times 10^{-23}$ s for heavy colliding nuclei ($A \approx 200$). Afterwards, the compressed zone expands, again passing through $\rho = \rho_0$ and exploding into non-interacting hadrons at $\rho < 0.3\rho_0$. The overall dynamical cycle is a sequence of shock compression, fireball, expansion and freezing out.

It took some time before suitable experimental probes for the high-density phase were devised. Before describing these, it is worth considering why the thermodynamic model should be applicable to these reactions. In particular, this model assumes that the shock volume (the fireball) is at rest in the centre-of-mass frame. The two interpenetrating volumes of nuclear matter thus have to stop down their initial relative motion, producing a fireball in which the transverse and longitudinal motions are equally distributed. This nuclear stopping process arises from elastic and, more effectively, inelastic scattering of the incoming nucleons, which populate the transverse degrees of freedom in the fireball, as well as pion production, isobar excitation and compressional (potential) energy. Essentially all the terms in the energy-density function $W(\rho, T)$ are separate agents creating internal centre-of-mass energy out of initial longitudinal energy. The degree of stopping is easy to check. Figure 3 shows streamer-chamber data[16] for head-on collisions between ^{40}Ar and Pb at 0.8 GeV per nucleon. For each collision, the mean transverse ($\langle p_T \rangle$) and longitudinal ($\langle p_L \rangle$) momentum of all final-state particles was determined, giving one point in the $\langle p_T \rangle$–$\langle p_L \rangle$ plane. Equipartition requires $\langle|p_T|\rangle = \pi/2\langle|p_L|\rangle$ in the centre-of-mass frame, and the data show that this is fulfilled on average. From the same experiment the total transverse energy is found to be in good agreement with the kinematic prediction under the assumption of complete stopping.

One of the key questions in extracting the W function from the data is that of how the internal energy is shared between thermal motion, compressional energy, newly created rest mass and so on. If we combine the rest-mass (m_0) component with the thermal energy (because the new $m_0c^2 \to 0$ as $T \to 0$), we could expect to determine the compressional energy

$W^{comp}(\rho, T=0)$ from the known total centre-of-mass (c.m.) energy (assuming full stopping) by an appropriate measurement of the thermal energy fraction W^{therm}:

$$E \text{ per nucleon (lab)} \rightarrow E \text{ per nucleon (c.m.)} \approx W^{comp}(\rho, T=0) + W^{therm}(\rho, T). \quad (4)$$

In other words, the ground-state function $W(\rho, \tau=0)$ can be approximately found if the thermal component can be measured and subtracted. The idea that the pion yield closely reflects the thermal energy fraction (intuitively, pions are created out of collision energy, with the potential energy remaining passive)[2,17] was exploited by the GSI-LBL streamer chamber collaboration[18,19]. Figure 4 illustrates how the supposed compressional energy was determined from systematic measurement[20] of the pion yield in central collisions of equal-mass pairs at $A \approx 40$ (Ar and KCl) and 140 (La and La). The ratio of pions produced to nucleons participating, $\langle n_\pi \rangle / A$, increases linearly with the centre-of-mass energy per nucleon above ~100 MeV per nucleon.

A calculation employing a thermochemical pion-production model that contains no potential energy gives a pion yield that increases more steeply with energy than does the experimental data. An arbitrary pion concentration is thus reached at an energy ε', according to the thermal model, which is lower than the energy ε when that concentration is actually observed. The difference between ε and ε' was interpreted as the potential energy expended in reaching the density $\rho(\varepsilon)$ from initial ground-state density ρ_0. This simple-minded assumption gives $\varepsilon - \varepsilon' \approx W^{comp}$ as a function of the centre-of-mass energy ε. From the Hugoniot-Rankine equation of hydrodynamic shock compression[1-3], ρ was determined as a function of ε, finally yielding a semi-empirical estimate of $W(\rho, T=0)$. The results[20] and a critique of this procedure are discussed below.

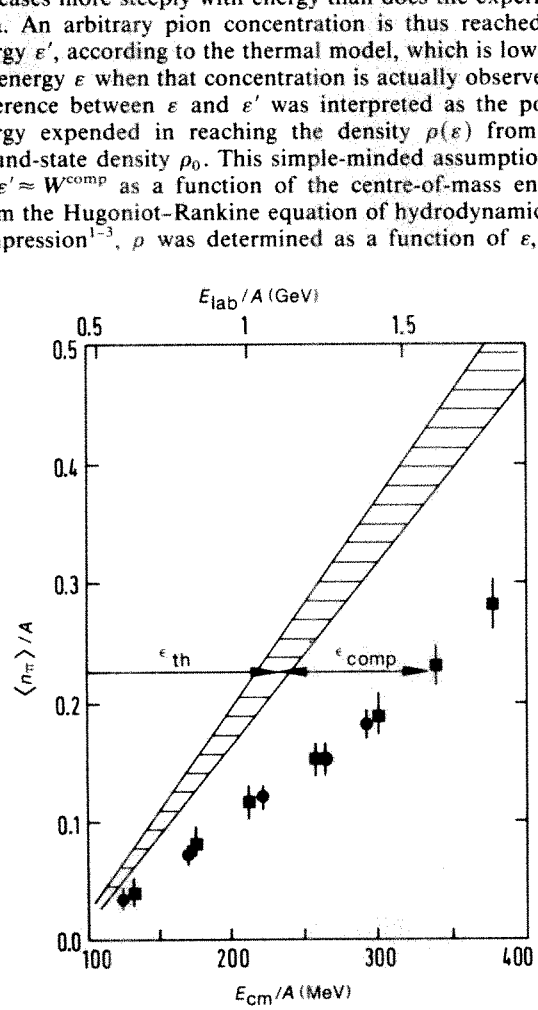

Fig. 4 Pion production rates from the fireball produced in a nuclear collision should be proportional to the thermal energy ε_{th} regardless of the potential energy. Data for the average number of pions produced $\langle n_\pi \rangle$ per nucleon participating in central collisions of Ar and KCl (squares), and La and La, (circles), as a function of the energy per nucleon in the centre-of-mass (E_{cm}, bottom scale) and laboratory (E_{lab}, top scale) frame, are used to estimate the compressional (potential) energy ε_{comp} according to equation (4). The hatched region indicates the predictions of thermal models. In these experiments, solid KCl was used as a target as the nearest non-gaseous, non-conducting equivalent to the Ar-atom projectiles (of mass 38).

Instead of trying to determine the energy function $W(\rho, T=0)$ why not aim directly at the pressure $P(\rho)$? The long-standing prediction[21] that collective pressure would lead to a sideways flow of emitted baryons was finally verified by the Plastic Ball collaboration[22]. Just as a water droplet splashes sideways on impact, nuclear matter develops a pressure field during interpenetration that displaces matter perpendicular to the beam axis. The final-state momentum distribution of all participating nucleons should thus be cigar-shaped in momentum space, a triaxial ellipsoid with its longest axis in the direction of favoured baryon flow. Its angle with respect to the beam axis is called the flow angle. When other variables are kept constant, the flow angle increases with the pressure in the reaction zone and so with the stiffness of the equation of state.

Figure 5 shows the results[23] from the Plastic Ball experiment for the flow angle in collisions between two gold atoms at various energies. This spectrometer has 971 single detectors arranged in a tightly-packed ball to measure particle emission angle, energy and identity for all charged final-state products, and has a planar surface to pick up the small forward angles [5]. The recorded events were first grouped according to their charged-particle or proton multiplicity (number of charged particles or protons created), where a low multiplicity is known to correspond to a peripheral collision and a high one to a central collision. The momentum tensor was then diagonalized for each event, yielding the flow angle Θ. The histograms in figure 5 show the distribution of $\cos\Theta$ for various bins of multiplicity and at five incident energies. In low-multiplicity events, the distribution peaks at $\Theta = 0°$: no preferential sideways flux occurs in grazing collisions, where only the dilute nuclear surfaces interact and there is little compression. A clear sideways peak developed for high-multiplicity events (near-central collisions).

Information about the equation of state can be obtained by comparing the data to theoretical calculations of the reaction dynamics that use a parameterized equation of state. This use of macroscopic models, such as hydrodynamics, and microscopic models that follow the nucleon collision cascades makes it clear that the equation of state is not directly measurable. All results from heavy-ion collisions require auxiliary models and are thus semi-empirical.

Nuclear collisions and astrophysics

The outcome of heavy-ion collision work on the nuclear-matter energy-density function $W(\rho, T=0)$ as it stood in 1986 is shown in Fig. 6, which includes results from the streamer chamber investigation of the 'pion thermometer'[18-20] as well as transverse energy data[24] measured by the Plastic Ball collaboration using a variation of the assumptions embodied in equation (4). These points agree closely with the W function deduced from fitting the flow angle and related data. The microscopic models employed here[25-27] were developed mostly by Stöcker, Aichelin and Bertsch as an extension of simple models of collision cascades by including the Pauli principle, microscopic effective nucleon-nucleon interactions and an average mean field, giving the nucleons a potential energy. This type of theory is known as the Vlasov-Uehling-Uhlenbeck (VUU) model. Figure 6 indicates a stiff equation of state. Note, however, that the data points start at a density $\rho/\rho_0 = 1.7$ and give no new insight into the result obtained from the monopole vibration in the immediate vicinity of $\rho = \rho_0$. But, as expected, W is approximately linear in ρ/ρ_0.

These results can be compared with astrophysical estimates of the equation of state for heavy neutron stars[28], also shown in Fig. 6. Analysis of 4UO900-40, a star with mass ~1.85 $M_\odot$, gives a much shallower W function. An even softer equation of state has been used by Baron, Cooperstein and Kahana (BCK) in the prompt supernova-bounce model[29]. The BCK model posits that a type II supernova arises from a compression-shock

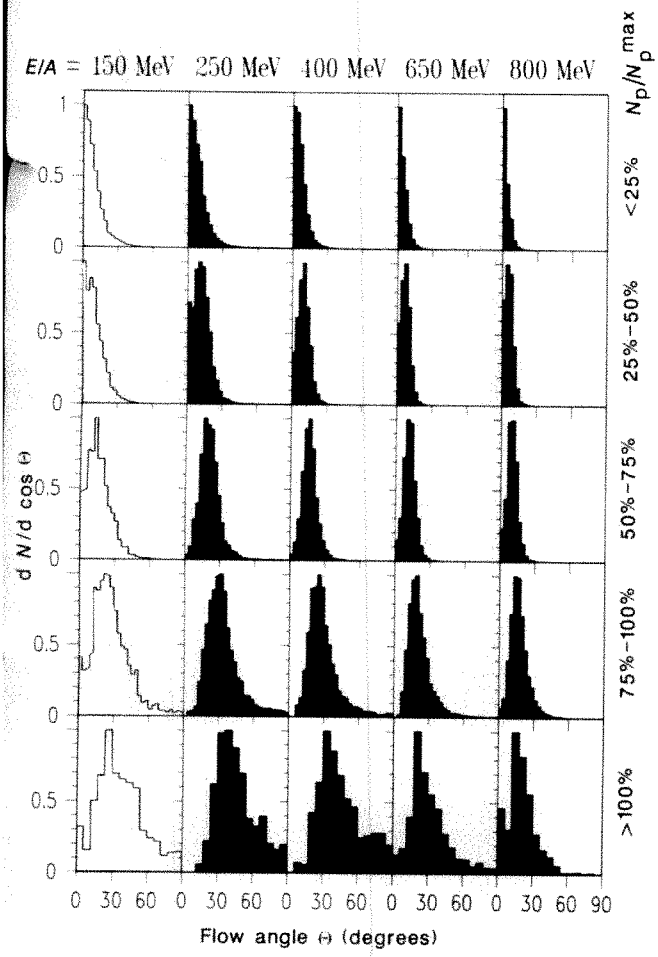

Fig. 5 In nuclear collisions at higher energies, the resultant blob of hot material is increasingly non-spherical. As a measure of this effect, the flow angle Θ between the beam axis and the longest axis of the fireball is measured. The figure plots the distribution of Θ in collisions of two gold atoms at five incident energies. The data are subdivided by multiplicity, the number of protons N_p in each event; five multiplicity bins are shown, with N_p divided by N_p^{max}, the average proton multiplicity in head-on events. N_p can occasionally exceed N_p^{max}. The flow angle peaks at 0° for low N_p (peripheral collisions) but develops a sideways shift at high N_p (central collisions).

explosion cycle of the iron core of a burned-out star of about 12–15 $M_\odot$, where the core has a mass of ~1.4 $M_\odot$. The shock explosion has to carry enough energy and matter outward to avoid being stalled by the mass of outer-shell material still falling inward. To create such a massive shock wave the collapse has to continue to very high density (small core radius) and thus traps a large amount of gravitational energy in the shock front that develops at the bounce point. The outer layer of the core then rebounds, the inner sections settling into a residual neutron star. A soft equation of state is required to reach high bounce-point densities, of $\rho \approx 4\rho_0$. The range of W functions that lead to a successful prompt-bounce simulation[29] is indicated in Fig. 6.

The first semi-empirical estimates of the energy–density function seem to be as contradictory as the qualitative *a priori* sketches (Fig. 2), but critical consideration of the theoretical models used in the derivation may remove some of the apparent contradictions.

● Nuclear collisions create hot hadronic matter, at temperatures up to 100 MeV, and contain up to 25% of their energy in pions and nucleon resonances. Supernovae, by contrast, are cold, proceeding at temperatures of about 10–15 MeV, neutron stars are at $T = 0$, and both are more nearly pure nucleon matter. The fireball nucleons move with a velocity of about $0.5c$ and the nucleon–nucleon potential is strongly velocity-dependent[30,31], so nuclear collisions do not reflect at all the

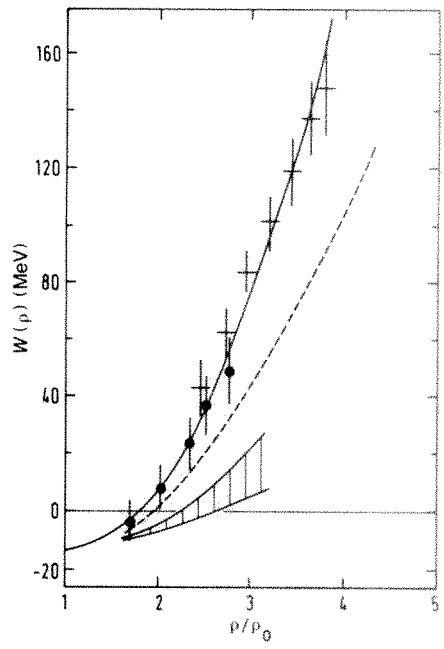

Fig. 6 The energy per nucleon, $W(\rho)$, can be obtained in a semi-empirical way by interpreting various observations with the help of simple theories. The figure shows the first generation of such estimates for $W(\rho)$, with ρ plotted against ρ_0, the ground-state nuclear-matter density. Heavy-ion collisions indicate a stiff response to compression (data points from pion data[20] (crosses) and radial energies[24] (circles), and VUU (solid) curve[25–27]) but the BCK model of supernova dynamics (hatched curve) demands a soft equation of state and indications from heavy neutron stars[28] (dashed curve) fall in between. These apparent contradictions may be due both to failings in the reaction models and to real differences between the dynamical conditions, such as temperature, in the different cases.

'cold' compressional energy. Our simplification (4) needs modification. Even with a correct model for the thermal energy $W^{therm}(\rho, T)$, the remaining fraction of the internal energy is not $W^{comp}(\rho, T=0)$ but a temperature-(velocity)-dependent $W^{comp}(\rho, T)$. First estimates of this effect indicate a considerable dynamical stiffening of the W function[31]. At $T = 100$ MeV and $\rho = 4\rho_0$, $W^{comp}(\rho, T)$ might exceed $W^{comp}(\rho, T=0)$ by 50 MeV. Thus the neutron star curve in Fig. 6 more probably represents the true $W^{comp}(\rho, T=0)$ and there are good reasons why the heavy-ion results are well above it.

● Theories have treated thermal degrees of freedom only to first order, ignoring possible shifts of nucleon, pion and resonance masses, and interaction cross-sections inside dense hadronic matter[32–34]. These 'effective masses' could increase the thermal part of the pressure, so that less static compressional pressure would be required to reproduce the sideways flow (Fig. 5). This might lower the VUU curve of Fig. 6 considerably.

● The prompt supernova-bounce model is by no means unchallenged[35–37]. There are many essential parameters in the physics of the simulation besides the equation of state that are not known with certainty, such as iron core mass, core entropy and degree of neutronization (the neutron concentration in the dense core). An alternative model[35,36] explains the supernova as a two-step process: the initial shock wave is allowed to stall at about 100 km radius but it is released again by reheating caused by absorption of a neutrino shower emitted by the neutronizing core. In this model stiffer equations of state than in the BCK model are admissible, but it remains to be shown that the energy release of the indirect mechanism suffices to account for the most recent supernova SN1987A.

The confrontration of data from nuclear experiments and astrophysics will obviously prompt further theoretical and experimental work, and the apparent contradictions may in the long run help to solve the puzzle of high-density hadronic matter.

Results from GSI's new heavy-ion synchrotrons will extend the work of LBL's Bevalac, but another nearby supernova would also be useful.

Outlook for quark matter

Whatever refinements and corrections to the equation-of-state data might be made in future, the smooth monotonic increase of $W(\rho)$ is unlikely to disappear. There is no indication yet of a phase transition, for up to about four times the ground-state density or for temperatures up to 100 MeV, where the total energy density amounts to ~ 0.7 GeV fm^{-3}. Lattice-gauge QCD, which suggests that hadronic matter is stable up to 2–3 GeV fm^{-3}, was first developed to study the quark–gluon wavefunctions of isolated hadrons, which have an energy density of ~ 0.5–1.0 GeV fm^{-3}, and was later adapted to study large volumes and high temperatures[8,38,39]. What accelerator energy is needed to match the critical conditions for the deconfinement transition from hadronic to quark–gluon matter? The step from 0.7 to 2.5 GeV fm^{-3} at first seems to demand a factor of about four in the centre-of-mass kinetic energy over and above the 0.4 GeV per nucleon attainable at the Bevalac, but at much higher energies we may not be able to count on the nuclear stopping power to accomplish complete thermalization, as observed in the Bevalac (Fig. 3). For example, at the energy of 32 GeV per nucleon obtained for the CERN Intersecting Storage Rings, a mere 15% of available centre-of-mass energy is thermalized in proton–proton collisions. Nucleus–nucleus collisions should provide greater stopping power because of sequential interactions in the extended medium, but we expect to need a twentyfold rather than a fourfold increase in the centre-of-mass energy, that is, 8–10 GeV per nucleon.

Because the CERN SPS could yield nuclear projectiles at 200 GeV per nucleon laboratory energy, which corresponds to 9.6 GeV per nucleon in the centre of mass, it was equipped with an injector for heavy ions by a collaboration between GSI, LBL and CERN. Using ^{16}O and ^{32}S projectiles, a set of pilot experiments were run to explore the new territory. The total beam energies of 3.2 TeV for ^{16}O and 6.4 TeV for ^{32}S set the world record for accelerator beams. The detectors are swamped with particles created in high-multiplicity events, as shown for a central collision of ^{16}O and Pb at 200 GeV per nucleon beam energy[40] (see panel on page 319). This event was recorded in the streamer chamber. About 280 charged particles are created in the collision, chiefly pions, kaons and protons. With an average spatial resolution of 1.5 mm, the total chamber volume of $2 \times 1.2 \times 0.7$ m^3 represents a potential information content of about 5 megabytes, enough to deal with multiplicities up to 500, such as those created in central interactions of ^{32}S and Au.

At CERN, a variety of techniques beside the streamer chamber are used to deal with this wealth of information: calorimetry to measure average energy-flow distributions, spectrometers for recording a small subfraction of the created particles at high precision, and some detectors that are set up specifically to find muon pairs or photons. Similar experiments have been conducted at the Brookhaven AGS synchrotron, with ^{16}O and ^{28}Si beams of 14.5 GeV per nucleon. Recent discussion of the first results from these new experiments indicates that the essential criteria for the formation of the quark–gluon matter are being met. Estimates[41] of the energy density reached in central collisions of ^{16}O and ^{32}S projectiles with heavy target nuclei are ~ 2.5–3 GeV fm^{-3}. This meets the critical deconfinement conditions predicted by lattice QCD, and shows that the nuclear stopping power is still effective at 200 GeV per nucleon. Pion correlation data demonstrate that a large, thermalized fireball volume with long lifetime is created at the centre of mass of the collision[42]. Furthermore, there is a suppression of the J/Ψ charm-meson production in central ^{16}O and ^{32}S collisions with U nuclei[43], which agrees with the prediction for charmonium production from deconfined matter[44].

Other data, on transverse momentum spectra, strange-particle production, photon production and total multiplicity are currently being examined for indications of new physics. Can they be understood by a simple reaction mechanism, such as cascading of standard nucleon–nucleon collisions, or do they require a different production mechanism which might bear the fingerprints of quark-matter production in the transient, high-density stage? A direct and unambiguous signature of quark-matter formation is still an evasive goal that awaits more theoretical work.

The study of GeV-per-nucleon-energy heavy-ion collisions has brought within our reach the equation of state for nuclear matter at densities relevant to supernovae and neutron stars. It has also added a new challenge to nuclear many-body theory by introducing relativity and a search for new dynamical models. Looking ahead, to increases in energy by factors of a hundred, the search for collective quark deconfinement is taking shape with discussions of suitable physics probes and instrumental development. The origin and nature of confinement is still an uncertain part of QCD, well proven only at short ranges (~ 0.1 fm), whereas confinement and deconfinement are intermediate-distance (0.5 fm) phenomena. Beside its fundamental interest, the existence and properties of a quark–gluon plasma state would be helpful in understanding of Big Bang expansion.

Until now, the two new research fields have not required a dedicated accelerator or large-scale experimental construction. GSI at Darmstadt is, however, now building a set of second-generation accelerators dedicated to nuclear-matter research. And experimenters at both CERN and Brookhaven are discussing the prospects for heavier projectiles, up to lead. Higher energies might follow later from the Large Hadron Collider project at Geneva, or the proposed Relativistic Heavy Ion Collider at Brookhaven. The analysis of the new data obtained with ^{32}S and ^{28}Si beams at CERN and Brookhaven will soon provide a firmer justification and direction for such developments.

NATO International Scientific Exchange Programmes

Applications are invited for support under the programmes of the NATO Science Committee

Advanced Study Institutes

ASIs are tutorial courses of two weeks' duration on new important topics for up to 100 scientists and research students. They aim at the dissemination of advanced scientific knowledge and the promotion of international contacts among scientists.

Advanced Research Workshops

ARWs are working meetings which enable scientists and engineers to review the state-of-the-art in specific topics in fast moving fields and to formulate recommendations for the future. They are of about five days' duration.

Collaborative Research Grants

CRGs are aimed at encouraging cooperation between researchers in different nations of the Alliance seeking solutions to common problems. The proposed research must be specific and carried out jointly by researchers in at least two member countries. Short reciprocal visits are funded.

Those wishing to organize and direct an ASI or an ARW, or participate in collaborative research should write for information and application forms to :

Scientific Affairs Division (Ref. 1989-1), NATO, B-1110 Brussels, Belgium

1989

Programme of meetings

The Advanced Study Institutes and Advanced Research Workshops to be held in 1989 are given in the following pages. **Each meeting is held under the responsibility of its director, to whom all requests for information, attendance or support should be addressed.** Participation or tuition fees are not required from participants, some of whom may obtain small grants from the meeting director to assist with travel and living expenses. Attendance at ASIs is open to all suitably-qualified applicants. Attendance at ARWs is usually by invitation only, but a few places are available for particularly well-qualified scientists upon application to the director.

Locations and dates noted in this list may change; titles and addresses have been abridged.

Many meetings are of an interdisciplinary nature - please check all subject areas.

In addition to the general Advanced Study Institutes and Advanced Research Workshops Programmes, NATO supports these types of meeting as part of a special effort in Cell to Cell Signals in Plants and Animals (CCS), Sensory Systems for Robotic Control (ROB), Condensed Systems of Low Dimensionality (CSLD), Advanced Educational Technology (AET) and Chaos, Order and Patterns : Aspects of Non-Linearity (COP).

PUBLICATION - The papers and discussions are published in the NATO ASI Series by : Plenum - Kluwer - Springer Verlag

LIFE SCIENCES — *SCIENCES DE LA VIE*

THE MOLECULAR BASIS OF CELL GROWTH REGULATION
Dr. M BARBACID, NCI-Frederick Cancer Res. Facil., Bldg. 539, P.O. Box B, Frederick, MD 21701, USA
4 - 16 March 1989 : Mallorca, Spain 267/87

SKIN PHARMACOLOGY AND TOXICOLOGY - RECENT ADVANCES
Prof. CL. GALLI, Ist. di Farmacologia e Farmacognosia, Via Balzaretti 9, 20133 Milan, Italy
9 - 19 April 1989 : Riva del Garda, Italy 265/88

DYNAMICS AND BIOGENESIS OF MEMBRANES
Dr. JAF OP DEN KAMP, Biochemistry Dept., Univ. of Utrecht, Padualaan 8, 3584 CH Utrecht, Netherlands
12 - 23 June 1989 : Cargèse, Corsica, France 276/88

PROTEIN STRUCTURE ENGINEERING
Prof. CA NICOLINI, Fac. of Medicine, Biophysics, V. Benedetto XV, 2, 16132 Genova, Italy
19 - 30 June 1989 : Erice, Italy 305/88

THREE DIMENSIONAL MOLECULAR STRUCTURE AND DRUG DESIGN
Dr. PJ GOODFORD, Molec. Biophysics Lab., Rex Richard Bldg., Sth. Parks Rd., Oxford, OX1 3QU UK
31 May - 11 June 1989 : Erice, Italy 306/88

OPTICAL SOURCES, LASERS AND SYNCHROTRON RADIATION - BIOLOGICAL EFFECTS AND HAZARD POTENTIAL
Prof. A RINDI, Sincrotrone Trieste, Padriciano 99, 34012 Trieste, Italy
10 - 20 May 1989 : Erice, Italy 464/88

BIOMECHANICS OF ACTIVE MOVEMENT AND DEFORMATION OF CELLS
Dr. N AKKAS, Dept. of Engineering, Ankara University, Ankara, Turkey
3 - 13 September 1989 : Istanbul, Turkey 466/88

ADVANCES IN BONE REGULATORY FACTORS: MORPHOLOGY, BIOCHEMISTRY, PHYSIOLOGY AND PHARMACOLOGY
Prof. A PECILE, Pharmacol., Chemother. & Medical Toxicol., Milan Univ., 32 via Vanvitelli, 20129 Milan, Italy
2 - 12 May 1989 : Erice, Italy 467/88

MOLECULAR ASPECTS OF MONOOXYGENASES AND BIOACTIVATION OF TOXIC CHEMICALS
Prof. E ARINC, Biological Sc. Dept., Middle East Techn. Univ., Ankara 06531, Turkey
27 August - 7 September 1989 : Çeşme, Izmir, Turkey 469/88

PROTEIN AND GENETIC ENGINEERING
Prof. BFC CLARK, Chemistry Dept., Aarhus Univ., Langelandsgade 140, 8000 Aarhus C., Denmark
3 - 16 September 1989 : Spetsai, Greece 609/88

ENZYMATIC AND MODEL CARBOXYLATION AND REDUCTION REACTIONS FOR CARBON DIOXIDE UTILIZATION
Prof. M ARESTA, Dip. Di Chimica, Campus Univ., 4 trav. 200 Re David, 70126 Bari, Italy
17 - 30 June 1989 : Apulia, Italy 611/88

TARGETING OF DRUGS : OPTIMIZATION STRATEGIES
Dr. G GREGORIADIS, Acad. Dept. of Med., Royal Free Hospital Sch., Pond St., London NW3 2QG, UK
24 June - 5 July 1989 : Cape Sounion, Greece 622/88

MOLECULAR BASIS OF PLANT AGEING
Prof. R RODRIGUEZ FERNANDEZ, Fac. de Biologia, Universidad, C/arias de Velasco, 33005 Oviedo, Spain
2 - 15 July 1989 : Ribadesella, Spain 665/88

EXPERIMENTAL EMBRYOLOGY IN AQUATIC PLANT AND ANIMAL ORGANISMS
Dr. HJ MARTHY, Lab. Arago (LA 117 CNRS) 66650 Banyuls-sur-Mer, France
11 - 23 September 1989 : Banyuls-sur-Mer, France 881/88

SYSTEMS APPROACHES TO DEVELOPMENTAL NEUROBIOLOGY
Prof. SS EASTER, Michigan Univ., Biology Div., 2109 Natural Sc. Bldg., Ann Arbor, MI 48109-1048, USA
1 June - 14 June 1989 : Varenna, Italy 883/88

PHYSICS AND CHEMISTRY — *PHYSIQUE ET CHIMIE*

THE NUCLEAR EQUATION OF STATE
Prof. W GREINER, Inst. für Theoret. Physik, J.W. Goethe-Univ., Postfach 11 19 32, 6000 Frankfurt am Main, Germany
21 May - 3 June 1989 : Peniscola, Spain 671/87

HYDROGEN-BONDED LIQUIDS
Dr. JC DORE, Physics Lab., Univ. of Kent, Canterbury, Kent CT2 7NR, UK
2 - 14 April 1989 : Cargèse, Corsica, France 941/87

METAL SPECIATION IN THE ENVIRONMENT
Prof. S GUCER, Inönü Univ., Dept. of Chemistry, 44069 Malatya, Turkey
9 - 20 October 1989 : Çeşme, Izmir, Turkey 180/88

ADVANCES IN NONRADIATIVE PROCESSES IN SOLIDS
Prof. B DI BARTOLO, Dept. of Physics, Boston College, Chestnut Hill, MA 02167, USA
15 - 29 June 1989 : Erice, Italy 259/88

LIQUIDS, FREEZING AND THE GLASS TRANSITION
Mr J. ZINN-JUSTIN, Serv. de Physique Théorique, CEN-SACLAY, 91191 Gif-sur-Yvette Cedex, France
3 - 28 July 1989 : Les Houches, France 275/88

PATTERNS, DEFECTS AND MATERIALS INSTABILITIES
Dr. D WALGRAEF, Serv. de Chimie Physique II, ULB, Bd du Triomphe, CP 231, 1050 Brussels, Belgium
4 - 15 September 1989 : Cargèse, Corsica, France 277/88

STRUCTURE, DYNAMICS AND EQUILIBRIUM PROPERTIES OF COLLOIDAL SYSTEMS
Prof. E WYN-JONES, Chemistry Dept., Univ. of Salford, Salford, M5 4WT, UK
10 - 23 September 1989 : Aberystwyth, UK 284/88

HADRONS AND HADRONIC MATTER
Dr. D VAUTHERIN, Inst. de Physique Nucléaire, 91406 Orsay, France
8 - 18 August 1989 : Cargèse, Corsica, France 286/88

PHASE TRANSITIONS IN SOFT CONDENSED MATTER
Prof. T RISTE, Inst. for Energy Technology, P.O. Box 40, 2007 Kjeller, Norway
4 - 14 April 1989 : Geilo, Norway 387/88

CHEMISTRY AND PHYSICS OF THE MOLECULAR PROCESSES IN ENERGETIC MATERIALS
Dr. SN BULUSU, Energetic Materials Div., Bldg. 3028, US Army ARDEC, Dover, NJ 07806-5000, USA
3 - 15 September 1989 : Altavilla Milicia, Sicily, Italy 472/88

NON-EQUILIBRIUM PROCESSES IN PARTIALLY IONIZED GASES
Dr. M CAPITELLI, Chemistry Dept., Bari Univ., Via Amendola 173, 70100 Bari, Italy
4 - 17 June 1989 : Maratea, Italy 613/88

PARTICLE PHYSICS
Prof. M LEVY, LPTHE, Univ. P. et M. Curie, 4 Pl. Jussieu, 75230 Paris, Cédex 05, France
18 July - 4 August 1989 : Cargèse, Corsica, France 624/88

CHAOS AND QUANTUM PHYSICS
Mr J ZINN-JUSTIN, Serv. de Physique Théor., CEN-SACLAY, 91191 Gif-sur-Yvette Cedex, France
1 - 31 August 1989 : Les Houches, France 625/88

BASIC CONCEPTS AND APPLICATIONS OF SCANNING TUNNELING MICROSCOPY (STM) AND RELATED TECHNIQUES
Dr. H ROHRER, IBM Research Div. Lab., 8803 Ruschlikon, Switzerland
17 - 29 April 1989 : Erice, Sicily, Italy 662/88

QUANTUM MECHANICS IN CURVED SPACE-TIME
Prof. J AUDRETSCH, Univ. Konstanz, Fak. für Physik, Postfach 5560, 7750 Konstanz 1, Germany
2 - 12 May 1989 : Erice, Sicily, Italy 666/88

COMPUTATIONAL ADVANCES IN ORGANIC CHEMISTRY (MOLECULAR STRUCTURE AND REACTIVITY)
Dr. C OGRETIR, Chemistry Dept., Anadolu University, 26470 Eskisehir, Turkey
30 July - 12 August 1989 : Altinoluk, Edremit, Turkey 850/88

APPLICATIONS OF STATISTICAL AND FIELD THEORY METHODS TO CONDENSED MATTER
Dr. AR BISHOP, Los Alamos Nat. Lab., T-11 MS-B262, Los Alamos, NM 87545, USA
21 May - 2 June 1989 : Evora, Portugal 858/88

RECENT DEVELOPMENTS IN HIGH-Tc SUPERCONDUCTIVITY
Prof. G BENEDEK, Dip. di Fisica, Universita, Via Celoria 16, 20133 Milano, Italy
1 - 15 July 1989 : Erice, Sicily, Italy 866/88

PHYSICS, GEOMETRY AND TOPOLOGY
Dr. HC LEE, Theor. Physics, Nuclear Labs, Chalk River, Ontario K0J 1J0, Canada
14 - 25 August 1989 : Banff, Alberta, Canada 870/88

OLEFIN METATHESIS AND POLYMERIZATION CATALYSTS -- SYNTHESIS, MECHANISM AND UTILIZATION
Dr. Y IMAMOGLU, Hacettepe Univ., Chemistry Dept., Beytepe/Ankara, Turkey
10 - 22 September 1989 : Antalya, Turkey 880/88

NEW FRONTIERS OF QUANTUMELECTRODYNAMICS AND QUANTUMOPTICS
Prof. AO BARUT, Physics Dept., University of Colorado, Boulder, CO 80309, USA
14 - 26 August 1989 : Istanbul, Turkey 901/88

THE MOLECULAR DYNAMICS OF LIQUID CRYSTALS
Prof. GR LUCKHURST, Chemistry Dept., The University, Southampton SO9 5NH, UK
11 - 23 September 1989 : Barga, Italy 905/88

NONLINEAR WAVES IN SOLID STATE PHYSICS
Prof. AD BOARDMAN, Physics Dept., Univ. of Salford, Salford, M5 4WT, UK
1 - 14 July 1989 : Erice, Sicily, Italy 913/88

APPLIED LASER SPECTROSCOPY
Prof. M INGUSCIO, Dip. di Scienze Fisiche, Mostra d'Oltremare Pad. 20, 80125 Napoli
28 August - 9 September 1989 : Lucca, Italy 929/88

HETEROGENEOUS MATERIALS : INTERACTION BETWEEN DISORDER AND BEHAVIOR
Prof. J-C CHARMET, EPCI LHMP, 10, rue Vauquelin, 85231 Paris Cedex 05, France
29 May - 9 June 1989 : Cargèse, Corsica, France (COP) 902/88

LOWER DIMENSIONAL SYSTEMS AND MOLECULAR DEVICES
Prof. RM METZGER, Univ. of Alabama, Dept. of Chemistry, Tuscaloosa, AL 35487, USA
12 - 23 June 1989 : Poros Island, Greece (CSLD) 930/88

ASTRONOMY AND ASTROPHYSICS — *ASTRONOMIE ET ASTROPHYSIQUE*

ACTIVE CLOSE BINARIES
Prof. I YAVUZ, Ege Univ., Astron. Space Science Dept., Bornova, Izmir, Turkey
11 - 22 September 1989 : Izmir, Turkey 258/88

PHYSICS OF THE EARLY UNIVERSE
Prof. MS LONGAIR, Royal Observatory, Blackford Hill, Edinburgh EH9 3HJ, UK
24 July - 11 August 1989 : Edinburgh, UK 468/88

BARYONIC DARK MATTER
Prof. D LYNDEN-BELL, Cambridge Univ., Inst. of Astronomy, Madingley Rd., Cambridge CB3 0HA, UK
17 - 27 July 1989 : Cambridge, UK 884/88

CHEMISTRY IN SPACE
Prof. JM GREENBERG, Astrophysics Lab., Huygens Lab., Niels Bohrweg 2, 2300 CA Leiden, Netherlands
10 - 20 May 1989 : Erice, Sicily, Italy 934/88

MATHEMATICS — *MATHEMATIQUE*

RECENT ADVANCES IN FOURIER ANALYSIS AND ITS APPLICATIONS
Dr. JS BYRNES, Prometheus Inc., 103 Mansfield Str., Sharon, MA 02067, USA
16 - 29 July 1989 : Il Ciocco, Italy 696/88

ORTHOGONAL POLYNOMIALS AND THEIR APPLICATIONS
Prof. P NEVAI, Mathematics Dept., Ohio State Univ., Columbus, Ohio 43210, USA
22 - 3 June 1989 : Columbia, S.C., USA 266/88

PARTIALLY INTEGRABLE NONLINEAR EVOLUTION EQUATIONS AND THEIR PHYSICAL APPLICATIONS
Dr. R CONTE, DPHG-PSRM, CEN-SACLAY, 91191 Gif-sur-Yvette, Cedex, France
21 - 30 March 1989 : Les Houches, France 500/88

FRACTAL GEOMETRY AND ANALYSIS
Prof. A DAIGNEAULT, Mathem. & Statist., Univ., CP 6128, Succ. A, Montreal, PQ H3C 3J7, Canada
3 - 21 July 1989 : Montreal, Canada 610/88

COMPUTATION OF CURVES AND SURFACES
Prof. M GASCA, Universidad, Fac. Ciencias, Dpto. Mat. Apl., 50009, Zaragoza, Spain
10 - 21 July 1989 : Canary Islands, Spain 663/88

SCIENCES DE LA TERRE

STOCHASTIC HYDROLOGY AND ITS USE IN WATER RESOURCES SYSTEMS
Prof. JB MARCO, Univ. Politecnica, P.O. Box 22012, 46080 Valencia, Spain
12 - 23 June 1989 : Nerja, Spain 871/88

PALEOECOLOGY, BIOSTRATIGRAPHY, PALEOCEANOGRAPHY, AND TAXONOMY OF AGGLUTINATED FORAMINIFERA
Dr. DB SCOTT, Geology Dept., Dalhousie Univ., Halifax, Nova Scotia, B3H 3J5, Canada
17 - 27 September 1989 : Tubingen, Germany 904/88

COMPUTER AND SYSTEMS SCIENCES
INFORMATIQUE ET SCIENCES DES SYSTEMES

LOGIC, ALGEBRA AND COMPUTATION
Prof. FL BAUER, Inst. Informatik, Techn. Universität, Postfach 20 2420, 8000 München 2, Germany
25 July - 6 August 1989 : Marktoberdorf, Germany 664/88

APPLIED SCIENCES AND ENGINEERING
SCIENCES APPLIQUEES ET INGENIERIE

DIFFUSION IN MATERIALS
Prof. AL LASKAR, Clemson Univ., Physics & Astron. Dept., Clemson, SC 29631, USA
12 - 25 March 1989 : Aussois, France 183/88

SULFUR-CENTERED REACTIVE INTERMEDIATES
Dr. C CHATGILIALOGLU, CNR, 40064 Ozzano Emilia, Bologna, Italy
18 - 30 June 1989 : Maratea, Italy 264/88

HIGH TEMPERATURE SUPERCONDUCTORS - PHYSICS AND MATERIALS SCIENCE
Dr. R KOSSOWSKY, Eng. Materials Dept., Penn. State Univ., POB 30, State College, PA 16804, USA
13 - 26 August 1989 : Bad Windsheim, Germany 285/88

OPTIMISATION AND DECISION SUPPORT SYSTEMS IN CIVIL ENGINEERING
Dr. BHV TOPPING, Civil Eng. Dept., Heriot-Watt Univ., Riccarton, Edinburgh EH14 4AS, UK
25 June - 6 July 1989 : Edinburgh, UK 287/88

ACTIVE PERCEPTION AND ROBOT VISION
Dr. AK SOOD, Computer Sc. Dept., George Mason Univ., 4400 Univ. Drive, Fairfax, VA 22030, USA
16 - 29 July 1989 : Maratea, Italy 470/88

Prof. J MONTALVAO E SILVA, CEMUL/IST,Technic. Univ., Ava. Rovisco Pais, 1096 Lisbon Codex, Portugal
10 - 22 April 1989 : Troia, Portugal 812/88

CARBON FIBERS AND FILAMENTS
Prof. JLC FIGUEIREDO, Chemical Eng. Dept., Fac. de Engenharia, University, 4099 Porto Codex, Portugal
15 - 27 May 1989 : Alvor, Portugal 714/88

MEMBRANE FILTRATION : THEORY AND APPLICATIONS
Prof. A HUYGHEBAERT, Food Techn. & Chem., Fac. of Agric. Sc., Coupure Links 653, 9000 Gent, Belgium
7 - 21 September 1989 : Maratea, Italy 722/88

TRANSPORT PROCESSES IN POROUS MEDIA
Prof. MY CORAPCIOGLU, Washington State Univ., Civil Eng. Dept., Pullman, WA 99164-3001, USA
9 - 18 July 1989 : Pullman, Washington, USA 882/88

ELECTROCHEMICAL AND OPTICAL TECHNIQUES FOR THE STUDY AND MONITORING OF METALLIC CORROSION
Prof. MGS FERREIRA, Chem. Eng. Dept., IST, Av. Rovisco Pais, 1096 Lisbon Codex, Portugal
2 - 14 July 1989 : Sintra, Portugal 900/88

NOVEL SILICON BASED HETEROSTRUCTURES
Dr. RA LEVY, AT&T Bell Labs., Murray Hill, NJ 07974, USA
17 - 28 July 1989 : Boca Raton, Florida, USA 903/88

ELECTRONIC PROPERTIES OF MULTILAYERS AND LOW DIMENSIONAL SEMICONDUCTOR STRUCTURES
Prof. L EAVES, University of Nottingham, Physics Dept., Nottingham NG7 2RD, UK
11 - 22 September 1989 : Castera Verduzon, France 924/88

SOCIAL & BEHAVIOURAL SCIENCES
SCIENCES SOCIALES ET DU COMPORTEMENT

MANAGING SCIENCE IN A STEADY STATE
Mr. P. HEALEY, Science Policy Support Group, 160 Great Portland St., London W1N 6DT, UK
1 - 13 October 1989 : Il Ciocco, Italy 290/88

SPEECH PRODUCTION AND SPEECH MODELLING
Dr. A MARCHAL, Inst. de Phonétique, 29 Ave. R. Schuman, 13621 Aix-en-Provence, France
17 - 29 July 1989 : Bonas, France 471/88

SIXTY-TWO YEARS OF UNCERTAINTY - HISTORICAL, PHILOSOPHICAL & PHYSICS INQUIRIES INTO THE FOUNDATIONS OF QUANTUM MECHANICS
Prof. AI MILLER, Dept. of Physics, Harvard University, Cambridge, MA 02138, USA
20 - 31 July 1989 : Erice, Sicily, Italy 947/88

Advanced Research Workshops

LIFE SCIENCES
SCIENCES DE LA VIE

GENERAL AND APPLIED ASPECTS OF HALOPHILIC MICROORGANISMS
Dr. F RODRIGUEZ-VALERA, Microbiology Div., Alicante Univ., Apdo. 99, Alicante, Spain
18 - 22 September 1989 : Alicante, Spain 586/87

PHARMACEUTICAL APPLICATIONS OF CELL AND TISSUE CULTURE
Dr. G WILSON, CIBA-GEIGY Pharmaceuticals, Wimblehurst Rd., Horsham, West Sussex RH12 4AB, UK
1 - 9 September 1989 : Bendor, France 952/87

SIGNAL PERCEPTION AND TRANSDUCTION IN HIGHER PLANTS
Dr. R RANJEVA, Ctr. de Phys. Veg., Univ. P. Sabatier, 118 Rte de Narbonne, 31062 Toulouse Cedex, France
27 - 7 July 1989 : Toulouse, France 260/88

EVOLUTION OF THE FIRST NERVOUS SYSTEMS
Dr. PAV ANDERSON, Whitney Laboratory, 9505 A1A South, St. Augustine, FL 32086, USA
27 - 5 July 1989 : St. Andrews, UK 272/88

DEVELOPMENTAL NEUROPATHOLOGY OF SCHIZOPHRENIA
Dr. SA MEDNICK, Univ. Southn Califor., Social Sc. Res. Inst., DRB-101, Los Angeles, CA 90089-1111, USA
29 August - 2 September 1989 : Il Ciocco, Italy 295/88

PENICILLIUM AND ASPERGILLUS
Dr. RA SAMSON, Centraalbureau voor Schimmelcultures, P.O.B. 273, 3740 AG Baarn, Netherlands
9 - 12 May 1989 : Amersfoort, Netherlands 308/88

THE EFFECT OF TIN UPON MALIGNANT CELL GROWTH
Prof. M. GIELEN, VUB, TW-AOSC-Room 86512, Pleinlaan 2, 1050 Brussels, Belgium
17 - 20 July 1989 : Brussels, Belgium 474/88

CONTROL OF METABOLIC PROCESSES
Dr. A CORNISH-BOWDEN, Ctre de Bioch.& Biol. Molec., 31, Chem. J-Aiguier, 13402 Marseille Cedex 9, France
1 - 15 April 1989 : Il Ciocco, Italy 475/88

MOLECULAR BIOLOGY OF AUTOIMMUNE DISEASE
Prof. AM McGREGOR, Dept. of Medicine, King's College Hosp. Med. Schl., Denmark Hill, London SE5 8RX, UK
16 - 20 April 1989 : Athens, Greece 479/88

RECENT ADVANCES IN DEVELOPMENT AND GERMINATION OF SEEDS
Dr. RB TAYLORSON, USDA, ARS, PSI, WSL, Rm. 36, Bldg. 001, BARC-West, Beltsville, MD 20705, USA
1 - 11 August 1989 : Williamsburg, Virginia, USA 570/88

CLINICAL AND PATHOPHYSIOLOGICAL ASPECTS OF INHERITED METABOLIC DISORDERS
Dr. F ÖZKARAGÖZ, Ministry of Health and Social Welfare, Sihiye, Ankara, Turkey
1 - 11 March 1989 : Antalya, Turkey 620/88

CONJUGATED POLYMERIC MATERIALS : OPPORTUNITIES IN ELECTRONICS, OPTO-ELECTRONICS AND MOLECULAR ELECTRONICS
Dr. J-L BREDAS, Serv. Chimie des Mat. Nouveaux, Univ. de l'Etat, Av. Maistriau, 21, 7000 Mons, Belgium
10 - 15 September 1989 : Mons, Belgium 852/88

SENSORY ABILITIES OF CETACEANS
Dr. JA THOMAS, Naval Ocean Systems Ctr., POB 997, Kailua, HI 96734-0997, USA
23 - 25 August 1989 : Rome, Italy 864/88

THE NEOCORTEX -- ONTOGENY AND PHYLOGENY
Prof. BL FINLAY, Cornell Univ., Psychology Dept., Uris Hall, Ithaca, NY 14853, USA
27 August - 2 September 1989 : Col d'Olen, Italy 886/88

HEALTH RELATED EFFECTS OF PHYLLOSILICATES
Dr. J. BIGNON, INSERM U.139, CHU H. Mondor, 94010 Creteil, Cedex, France
16 - 17 March 1989 : Paris, France 890/88

SELECTIVE ACTIVATION OF DRUGS BY REDOX PROCESSES
Prof. GE ADAMS, MRC Radiobiology Unit, Chilton, Didcot, Oxon OX11 ORD, UK
28 August - 1 September 1989 : Fermo, Italy 892/88

REGULATION OF EXTRAVASCULAR FIBRINOLYSIS IN NERVOUS SYSTEM DEVELOPMENT
Dr. BW FESTOFF, Veterans Admin. Medical Ctr., 4801 Linwood Blvd. Kansas City, MI 64128, USA
23 - 29 July 1989 : Bellagio, Italy 896/88

DEMOGRAPHICAL, PHYSIOLOGICAL, GENETICAL AND BEHAVIORAL ASPECTS OF POPULATION BIOLOGY OF PASSERINE BIRDS
Dr. J BLONDEL, CNRS, Ctr. L. Emberger, BP 5051, 34033 Montpellier Cedex, France
3 - 8 October 1989 : Evisa, Corsica, France 923/88

EVOLUTIONARY BIOGEOGRAPHY OF THE MARINE ALGAE OF THE NORTH ATLANTIC
Dr. GR SOUTH, Huntsman Marine Sc. Ctr., Brandy Cove Rd., St. Andrews, New Brunswick, E0G 2X0, Canada
3 - 6 September 1989 : New Brunswick, Canada 931/88

RNA 3' END FORMATION
Dr. JL MANLEY, Columbia Univ. 713 Fairchild Ctr., New York, NY 10027, USA
13 - 17 September 1989 : Oxford, UK 933/88

MOLECULAR SIGNALS IN MICROBE-PLANT SYMBIOTIC AND PATHOGENIC SYSTEMS
Prof. EJJ LUGTENBERG, Univ., Botanical Laboratory, Nonnensteeg 3, 2311 VJ Leiden, Netherlands
21 - 26 May 1989 : Flevohof, Netherlands (CCS) 851/86

RECOGNITION AND RESPONSE IN PLANT-VIRUS INTERACTIONS
Dr. RSS FRASER, IHR-Littlehampton, Worthing Rd., Littlehampton, West Sussex, BN17 6LP, UK
12 - 16 April 1989 : Chichester, UK (CCS) 920/87

TRANSDUCING PATHWAYS - ACTIVITATION AND DESENSITIZATION
Prof. TM KONIJN, Univ. Zoological Lab., Postbox 9516, 2300 RA Leiden, Netherlands
24 - 27 May 1989 : Noordwijkerhout, Netherlands (CCS) 921/87

INFORMATION PROCESSING OF CHEMICAL SENSORY STIMULI IN BIOLOGICAL AND ARTIFICIAL SYSTEMS
Dr. D SCHILD, Humboldtallee 23, 3400 Göttingen, Germany
23 - 26 July 1989 : Göttingen, Germany (CCS) 359/88

PARALLELS IN CELL TO CELL JUNCTIONS IN PLANTS AND ANIMALS
Dr. AW ROBARDS, Inst. for Appl. Biology, University of York, York YO1 5DD, UK
2 - 7 July 1989 : York, UK (CCS) 605/88

CELLULAR AND MOLECULAR BIOLOGY OF MYELINATION
Dr. G JESERICH, Universität, Dept. Biology/Chemistry, Barbarastr. 7/11, 4500 Osnabrück, Germany
28 August - 2 September 1989 : Osnabrück, Germany (CCS) 907/88

MECHANISM OF FERTILIZATION -- PLANTS TO HUMANS
Dr. B DALE, Stazione Zoologica, Villa Communale, 80121, Naples, Italy
Spring 1989 : Sorrento, Italy (CCS) 921/88

PHYSICS AND CHEMISTRY — PHYSIQUE ET CHIMIE

FROM GEOMETRY TO THERMODYNAMICS -- COMMON PROBLEMS OF QUASI-CRYSTALS, LIQUID CRYSTALS AND INCOMMENSURATE INSULATORS
Dr. J-C TOLEDANO, C.N.E.T., 196, Av. H. Ravera, 92220 Bagneux, France
4 - 8 September 1989 : Preveza, Greece 269/88

RADIATIVE CORRECTIONS - RESULTS AND PERSPECTIVES
Dr. N DOMBEY, Physics Div., Univ. of Sussex, Brighton BN1 9QH, East Sussex, UK
9 - 14 July 1989 : Brighton, UK 524/88

THE PHYSICS AND CHEMISTRY OF ARBIDES, NITRIDES AND BORIDES
Dr. R FREER, Materials Science Ctre, UMIST, Grosvenor St, Manchester M1 7HS, UK
18 - 22 September 1989 : Manchester, UK 571/88

NUCLEAR MATTER AND HEAVY ION COLLISIONS
Dr. M SOYEUR, Serv. de Phys. Théorique, CEN-SACLAY, 91191 Gif-sur-Yvette, Cedex, France
7 - 16 February 1989 : Les Houches, France 595/88

BIO-MECHANICAL TRANSPORT PROCESSES
Prof. F MOSORA, Univ. de Liège, Inst. de Physique, 4000 Sart-Tilman par Liège 1, Belgium
9 - 14 October 1989 : Corgèse, Corsica, France 617/88

ION BEAMS MODIFICATION AND PROCESSING IN HIGH-Tc SUPERCONDUCTORS -- PHYSICS AND DEVICES
Dr. CA ENGLISH, Materials Development Div. B 393, Harwell, Oxon OX11 ORA, UK
10 - 12 April 1989 : Minster Lovell, UK 908/88

SEMICONDUCTORS
Prof. P HIRSCH, Oxford Univ., Metallurgy Dept., Parks Rd., Oxford OX1 3PH, UK
5 - 8 April 1989 : Oxford, UK 909/88

DYNAMICS OF POLYATOMIC VAN DER WAALS COMPLEXES
Dr. N HALBERSTADT, Univ. Paris-Sud, Lab. de Photoph/Molec., Btm. 213, 91405 Orsay, France
21 - 26 August 1989 : Bonas, France 928/88

RELATIONSHIP BETWEEN THE PHYSICOCHEMICAL PROPERTIES OF ZEOLITIC SYSTEMS AND THEIR LOW DIMENSIONALITY
Dr. D BARTHOMEUF, Lab. de Réactivité de Surface & Structure, Univ. P&M Curie, 75252 Paris Cedex 05, France
24 - 28 April 1989 : Chantilly, France (CSLD) 622/87

SPECTROSCOPY OF SEMICONDUCTOR MICROSTRUCTURES
Dr. G FASOL, Cavendish Lab., Madingley Rd., Cambridge CB3 0HE, UK
9 - 13 May 1989 : Venice, Italy (CSLD) 655/88

KINETICS OF ORDERING AND GROWTH AT SURFACES
Prof. MG LAGALLY, Univ. Metall. & Mineral Eng. Dept., 1509 University Av., Madison, WI 53706, USA
18 - 22 September 1989 : Sesimbra, Portugal (CSLD) 865/88

SCIENCE AND ENGINEERING OF 1- AND 0-DIMENSIONAL SEMICONDUCTORS
Dr. SP BEAUMONT, Univ. of Glasgow, Electronics & Electr. Eng. Dept., Glasgow G12 8QQ, UK
4 - 7 April 1989 : Cadiz, Spain (CSLD) 950/88

SELF TRAPPING OF VIBRATIONAL ENERGY IN PROTEIN
Prof. PL CHRISTIANSEN, Lab. of Appl. Mathemat. Physics, Tech. Univ., Bldg 303, 2800 Lyngby, Denmark
30 July - 5 August 1989 : Thisted, Denmark (COP) 672/88

NONLINEAR EVOLUTION OF SPATIO-TEMPORAL STRUCTURES IN DISSIPATIVE CONTINUOUS SYSTEMS
Prof. FH BUSSE, Universität, Physik. Inst., Postfach 10 12 51, 8580 Bayreuth, Germany
24 - 29 September 1989 : Streitberg, Germany (COP) 932/88

NONLINEAR WAVE PROCESSES IN EXCITABLE MEDIA
Dr. AV HOLDEN, Physiology Dept., University of Leeds, Leeds LS2 9NQ, UK
11 - 15 September 1989 : Leeds, UK (COP) 937/88

ASTRONOMY AND ASTROPHYSICS
ASTRONOMIE ET ASTROPHYSIQUE

THE NUMERICAL MODELLING OF NONLINEAR STELLAR PULSATIONS -- PROBLEMS AND PROSPECTS
Prof. JR BUCHLER, Physics Dept., Univ. of Florida, Gainsville, FL 32611, USA

Reader Service No.16

Geophysical evidence for 'thick-skinned' crustal deformation in central Australia

Bruce R. Goleby*†, Russell D. Shaw*†, Cedric Wright*, Brian L. N. Kennett† & Kurt Lambeck†

* Bureau of Mineral Resources, Geology and Geophysics, GPO Box 378, Canberra ACT 2601, Australia
† Research School of Earth Sciences, Australian National University, GPO Box 4, Canberra ACT 2601, Australia

Until now, there has been no clear evidence from deep seismic reflection profiles of crustal faults that displace the Moho. New data from central Australia show such a structure in a region characterized by large thrust structures, large gravity anomalies and abrupt changes in teleseismic travel times. Here the principal thrust, the Redbank Deformed Zone, cuts through the crust, and the Moho is significantly displaced across it. The geological and geophysical evidence leads to a model of thick-skinned crustal deformation which occurred in an intra-cratonic environment in late Devonian time.

A CURRENT controversy in the study of continental tectonics is whether deformation initially involves the entire crust and the upper mantle (that is, a 'thick skin') or whether it is controlled by detachment zones within the crust so that much of the folding and imbricate thrusting is restricted to the upper crust alone (a 'thin skin')[1]. This controversy has been introduced recently to attempts to understand the formation of the Pyrenees of Europe, for which both thick- and thin-skinned interpretations have been proposed[2]. Well-known examples of thin-skinned tectonics include the Appalachians and Rocky Mountains of the United States and the Alps of Europe. Thick-skinned models are characterized by major planar crustal faults which cut the entire crust at moderately steep angles. Examples of thick-skinned tectonics include the Wind River Thrust of North America, the Grenville Front region of Canada and the Flannan and Outer Isles Thrusts of Great Britain. The Grenville Front in particular is an excellent example of thick-skinned tectonics[3]. Another example occurs in central Australia, and exhibits clear evidence of a major offset in Moho depth across the structure.

The tectonic setting of central Australia is characterized by a series of late Proterozoic–Palaeozoic basins and an exposed geological basement of middle Proterozoic age[4–7]. The basins include the Amadeus and Ngalia Basins, and the principal region of exposed basement is the Arunta Block (Fig. 1). The region as a whole is characterized by relatively flat topography and by major east–west-trending gravity anomalies (of peak-to-trough amplitudes exceeding 1,400 $\mu m\ s^{-1}$ (140 mgal)) (Fig. 1). Teleseismic travel-time anomalies of up to 1.5 s have also been recorded across the region over distances of a few tens of kilometres[8]. Major east–west-trending thrust zones occur within the Arunta Block. These observations, together with the geological evidence that the thrusts were last reactivated in an intracratonic environment in late Devonian to early Carboniferous times[9] with little subsequent tectonism, makes this basin-and-block structure quite unusual and raises a number of fundamental questions. What is the deep crustal structure beneath these basins and blocks? What were the driving forces that shaped these and other structures? How has this anomalous structure been supported since the time of the last major thrusting event[10]? Several models have been proposed in response to such questions[9–12], and a 500-km-long north–south deep-seismic-reflection traverse has been recorded by the Bureau of Mineral Resources across the Amadeus Basin and Arunta Block[13]. Only the northern section, extending from north of the Ngalia Basin to a point south of the major thrust zone (the Redbank Thrust or Redbank Deformed Zone), is discussed here (the section A–A′ in Fig. 1). Explosive sources were used throughout and the resulting deep-seismic-reflection data provide excellent resolution of the crustal structure down to an average depth of ~40 km.

Regional geology

The Amadeus Basin[4], bounded to the north by the Arunta Block and to the south by the Musgrave Block, contains up to 14 km of sediments of late Proterozoic (~900 Myr) to late Palaeozoic (~300 Myr) age. The maximum thickness of sediments occurs at the faulted and upturned northern margin, where the Arunta Block has been thrust up and over the basin sediments to form the Amadeus Homocline. Several deformation events have been identified within the basin sediments, with the major and final one having occurred at the time of the Alice Springs orogeny in the late Devonian to early Carboniferous. The northern margin of the Ngalia Basin is also fault-controlled and the last major orogenic event (the Mt Eclipse orogeny) occurred at about the same time as the Alice Springs orogeny[5]. The Ngalia Basin is not an important feature in the seismic-reflection section discussed here because the sediment thickness does not exceed 1 km. Further to the west the sedimentary section exceeds 6 km in thickness.

The Arunta Block can be characterized by three tectonic provinces[6,7], each of which underwent separate histories of deformation and metamorphism during early to middle Proterozoic time (Fig. 1). The Southern Arunta Province, between the Redbank Thrust and the northern margin of the Amadeus Basin, is predominantly an amphibolite-grade granitic gneiss, in contrast to the central province which is characterized by felsic and relatively minor mafic granulite that was metamorphosed at depths of ~25 km at ~1,750–1,800 Myr. The Northern Arunta Province consists of low-grade metasediments of amphibolite and greenschist facies. The southern and central provinces are separated by the Redbank Thrust, a 7–10-km-wide east–west-trending zone of anastomosing mylonites which dips northwards at about 45°. The northern and central provinces are separated by large granitoid intrusions and possibly by moderately to steeply dipping faults. Another major structural feature is the Ormiston Thrust Zone some 13 km south of, and running sub-parallel to, the Redbank Thrust. At the northern end of the line, north of the Ngalia Basin, the tectonics becomes complicated by an oblique lineament known as the Weldon Tectonic Zone[5,6]. Apart from this last feature the tectonic strike is primarily east–west and approximately orthogonal to the seismic reflection line.

Deep seismic reflections

All signal processing was carried out using pseudo-true-amplitude techniques, in which energy loss is assumed to occur only

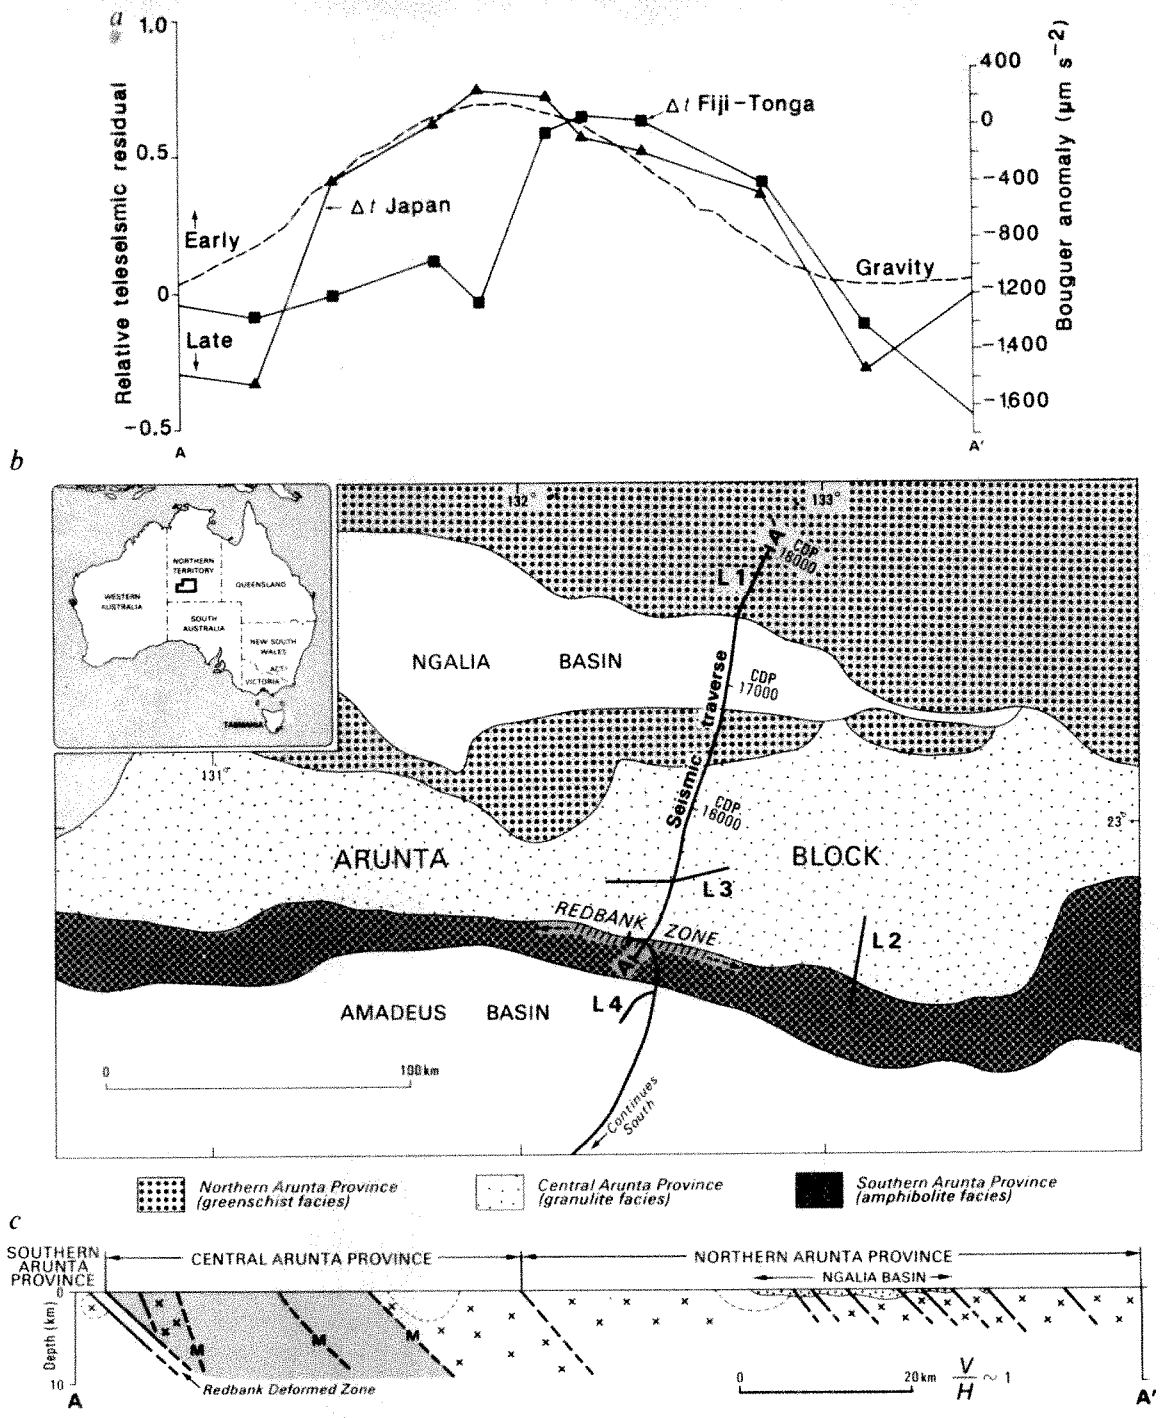

Fig. 1 Location diagram showing the principal tectonic elements of the central Australian region (*b*) and the position of the northern portion of the Central Australian traverse, L1, where it crosses the Arunta Block. Gravity and teleseismic travel-time profiles[1] (*a*) and a schematic geological cross-section (A–A′, shown in *b*) along this traverse are also shown (*c*). The shading schemes used in *b* and *c* are different. The travel-time anomalies are for earthquakes from two different regions: Japan from the north and Fiji–Tonga from the east.

by spherical divergence and losses associated with attenuation are neglected. Major efforts to enhance the deep seismic signal were not required during processing. Figure 2 illustrates the variations in the processed signal throughout the seismic section for a collection of single-shot gathers.

Line drawings of the deep-seismic-reflection section are shown in Fig. 3 and are used here instead of seismic-reflection sections because of the greater clarity of the former and to avoid some of the difficulties of migrating deep seismic data[14]. Each line segment in these drawings represents a coherent seismic reflection seen on the original seismic section. Results obtained with different stacking methods are illustrated for both unmigrated and migrated sections. The migrated sections are produced by migrating each line segment of the line drawin to its time–depth position. The coherency-stacking method (Fi 3*a*) enhances coherent and continuous dipping and flat reflec tors. The corresponding section of migrated line segments i shown in Fig. 3*b*. The energy-stacking method (Fig. 3*c*) empha sizes packets of energy that are not affected by signal polarity and enables an easier correlation of reflections because they ar enhanced above the generally noisy background of the seismi sections[15]. The corresponding line-segment-migrated section shown in Fig. 3*d*. Both migrations were performed with a velo ity–depth function that varied from 5.5 km s^{-1} at shallow depth to 6.2 km s^{-1}.

Other stacking methods have also been used, and they produ

the same general features illustrated in Fig. 3. In addition, most of the deep-reflection events seen on these processed sections can also be identified on the single-fold displays (see, for example, Fig. 2).

The principal features of the line drawings are illustrated in Figs 3 and 4. A general feature of the data is that the strength and depth of penetration of the reflected signal is unusually high for deep seismic data; the signal is still strong to reflection times of 14 s with an unusually high frequency content. Frequencies up to 80 Hz at reflection times of 5–6 s and to 60 Hz at 6–10 s are common, particularly within the Northern Arunta Province. Because conditions around the source were similar to those encountered elsewhere in Australia, the high-frequency content implies that the rocks at depths of 15–20 km have a very high quality factor Q (that is, low attenuation)[16].

The Precambrian Arunta Block exhibits reflections of varying strength throughout the section and is not characterized by the marked non-reflective upper-crustal zone that is seen in similar sections of Precambrian regions elsewhere in the world[17]. Instead, the Arunta section is dominated by northerly-dipping reflections throughout the entire crust, which coincide with surface evidence of thrusts and faults. The surface faults and mylonite zones corresponding to the Redbank Thrust correspond to reflections in the seismic section that can be traced to depths of at least 30–35 km and possibly down to 50 km (Figs 3*b* and 4*a*), dipping at an angle of about 35–40°. Three-dimensional modelling has shown that such faults can generate strong reflected signals[18]. A second band of northerly- but shallower-dipping reflections lies below this feature and its extension to the surface suggests that it corresponds to the Ormiston Thrust, which appears to merge with the Redbank Thrust at mid-crustal levels. Beneath the Southern Arunta Province, the reflectors down to 30 km depth are predominantly sub-horizontal, in contrast to the generally northerly-dipping reflectors (~35°) beneath the central and northern Provinces. This transition in dip coincides with the Redbank Thrust. We interpret the Southern Arunta Province as extending to the underthrust foot wall of this thrust, down to a depth of at least 30 km. The crust north of the Redbank Thrust exhibits further moderately dipping (35–40°) reflections which correspond to surface outcrops of mapped faults or of faults inferred from aeromagnetic surveys. These faults and shear zones extend down to a depth of ~35 km and divide the crust into a series of 'blocks', each of which has similar seismic characteristics and which is bounded by the dipping faults. Seismic-reflection sections of Precambrian crust recorded elsewhere in the world have not exhibited such large numbers of dipping faults and inferred tilted blocks. The shallow zone of low reflectivity (<2 s travel time) seen to the north of the Redbank Thrust coincides with mapped outcrops of granitoid and granitic gneiss, and this whole region is interpreted as granitic material. Sub-horizontal reflections occur at the base of this granitic zone, as well as within the crustal blocks (Fig. 3*b*), and are attributed to compositional layering. They can, therefore, be used as marker horizons which indicate the present attitude of the original crustal layering. Within some blocks these sub-horizontal events are truncated against the dipping faults, suggesting that the deformation of the crust occurred by movement along the faults, with little or no rotation of the crustal blocks.

Deep-crustal reflections in the migrated sections are more prominent beneath the northern and southern provinces than beneath the Central Arunta Province (Figs 3*b*, *d* and 4*a*). In particular, the two migrated sections beneath the central province exhibit a relatively transparent zone at about 25–30 km depth, where the density of reflections is comparable to those usually seen in other sections at depths greater than 35–40 km. Energy is received from reflections beneath this transparent zone, indicating that this region is seismically non-reflective rather than being a region of high attenuation. The continental crust–mantle boundary is often defined in seismic-reflection

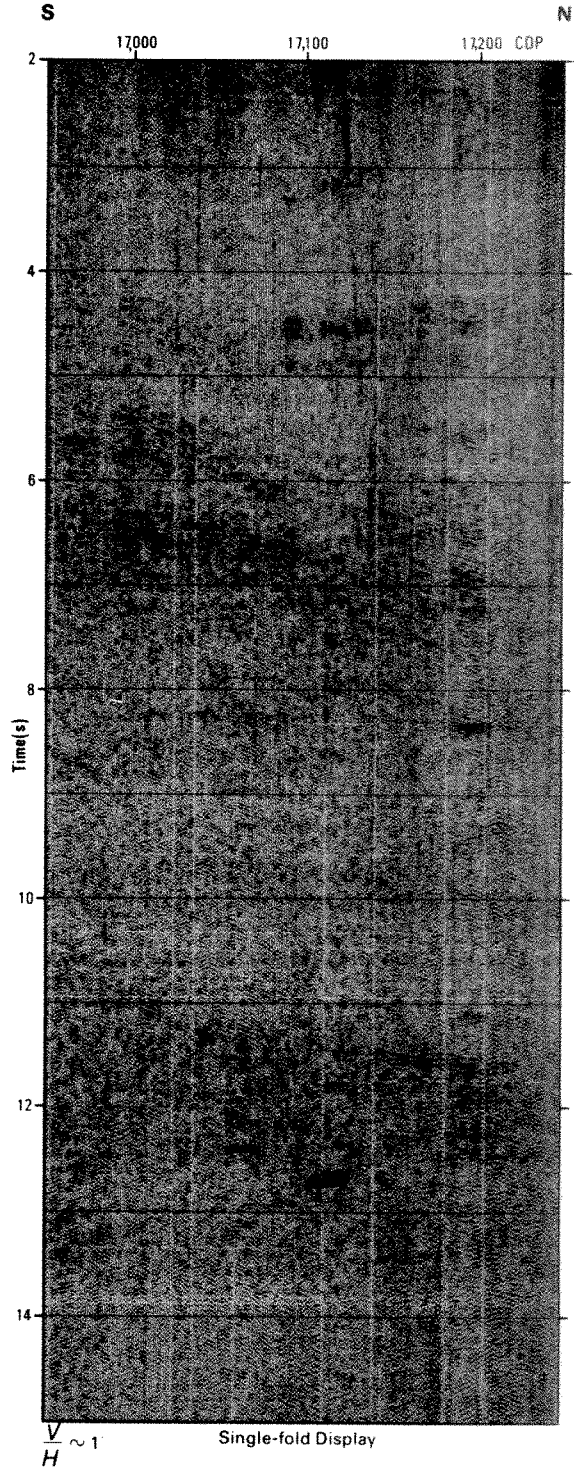

Fig. 2 Portion of a single-fold display, without gain correction, from within the Northern Aunta Province. This is a pseudo-true-amplitude section and illustrates the strength and continuity of the deep signals.

sections as the base of a zone of strong, deep and layered reflections overlying a non-reflective region corresponding to the upper mantle[19,20]. Beneath the northern part of the Arunta Block, the appropriate choice for this boundary would be at about 35–40 km depth but it is less well defined south of the Redbank Thrust. One interpretation is that this boundary occurs at the base of the lowest reflections that are seen at about 50 km depth (Figs 3*b* and 4*a*); this indicates a thicker-than-normal crust and a significant variation in the crustal thickness between the southern and northern provinces. Sediments in the Amadeus

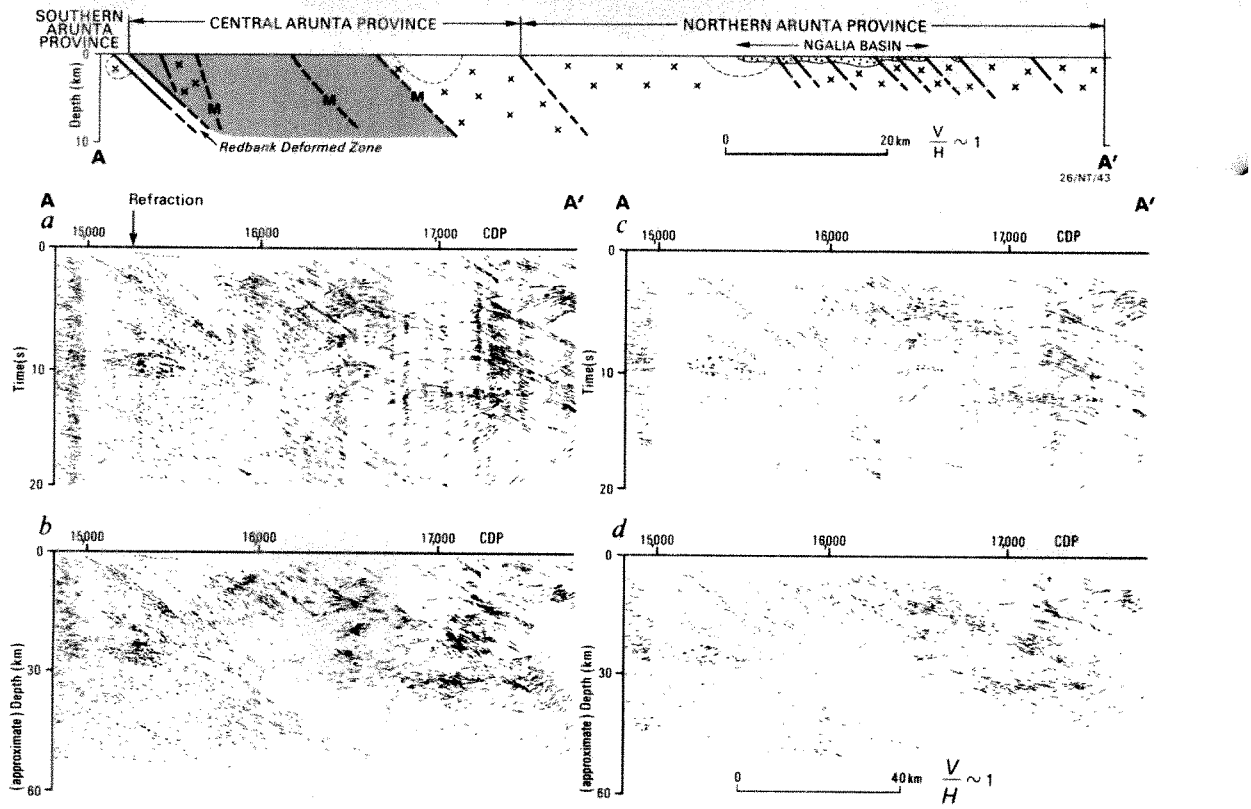

Fig. 3 Unmigrated and migrated line drawings of the seismic-reflection section from the Central Australian traverse. *a*, Unmigrated coherency stack. *b*, Line-migrated version of *a*. *c*, Unmigrated energy stack. *d*, Line-migrated version of *c*.

Basin, south of the Redbank Thrust, have a maximum thickness of 10–14 km and the gravity, teleseismic travel-time anomalies and deep-crustal-reflection data do not indicate any discontinuity in the deep-crustal structure across the basin margin; the interpretation that the base of the crust is at 50 km depth therefore implies that the sediments have been deposited on a crust of approximately normal thickness. This is consistent with a predominantly compressional regime during the later part of the basin formation process. The large negative gravity anomalies, the late teleseismic travel-time arrivals (Fig. 1) across the northern part of the Amadeus Basin and the southern part of the Arunta Block south of the Redbank Zone, and an east–west seismic reflection profile, all favour a crustal thickness of more than 50 km in this region. We therefore interpret the reflection record beneath the footwall of the Redbank Thrust as a broad crust–mantle transition zone of 15–20 km thickness extending down to a depth of at least 50 km. Beneath the Northern Arunta Province this transition zone is considerably thinner and occurs at a shallower depth. The seismically transparent zone immediately north of the Redbank Thrust is interpreted as a region of predominantly mantle material emplaced by major thrusting on the Redbank and Ormiston Thrusts.

Figure 4*b* illustrates the crustal structure derived from the teleseismic travel-time anomalies for the part of the Arunta Block corresponding to the extent of the seismic line. The model has poor resolution north of the Ngalia Basin. The principal requirements of this data set are a zone of relatively high-velocity material dipping steeply northwards such that its continuation to the surface coincides approximately with the Redbank Thrust and the granulite terrain to the north of it, and relatively low-velocity material in the form of a down-thrust wedge to the south of the Redbank Thrust[10]. These features are consistent with the reflection data.

Gravity modelling

The Bouguer gravity anomalies along the seismic line are characterized by a relatively long-wavelength variation of ~1,400 μm s^{-2} peak-to-trough amplitude. The free-air anomalies exhibit a very similar variation, and conventional models of isostatic compensation fail to explain these observations[21]. Near-surface variations in crustal densities of surface outcrop rocks range from 2.5 g cm^{-3} for the Palaeozoic sediments in the basin to 2.95 g cm^{-3} for the high-grade granulite facies rocks north of the Redbank Thrust[10]. If such lateral variations persist down to 10 km depth they would explain about 50% of the observed magnitude of the gravity anomalies. However, the wavelength predicted for these anomalies is considerably less than that observed, and the observed maximum anomaly is offset from the surface exposure of high-density granulites by more than 50 km. Furthermore, there are no significant short-wavelength changes observed across either the Redbank Thrust or the Amadeus Homocline, despite the existence of density contrasts across these surfaces[10]. Overall, these observations suggest a deep origin for the major part of the observed gravity field over the southern part of the Arunta Block. Figure 5 shows the gravity field predicted by the model, using density values based on surface-rock exposure[9,10]. Agreement with the observed field is satisfactory and could be further improved by minor adjustments to the boundaries that separate regions of different densities or by introducing density gradients within the regions. Most importantly, the model makes good predictions of both the amplitude and the wavelength of the observed field.

A tectonic model for the Arunta Block

The deep-seismic-reflection data favour a tectonic model in which the major deformation within the Arunta Block occurred along faults and shear zones that extend from the surface to the crust–mantle boundary (that is, a 'thick-skinned' model). In particular, there is no seismic evidence for mid-crustal ramps branching from a relatively shallow-dipping sole thrust, which is a principal characteristic of the thin-skinned models[22]. In this sense, the Arunta structure is comparable to both the Flannan and Outer Isles Thrusts of Scotland[23], the Pyrenees of Europe[2],

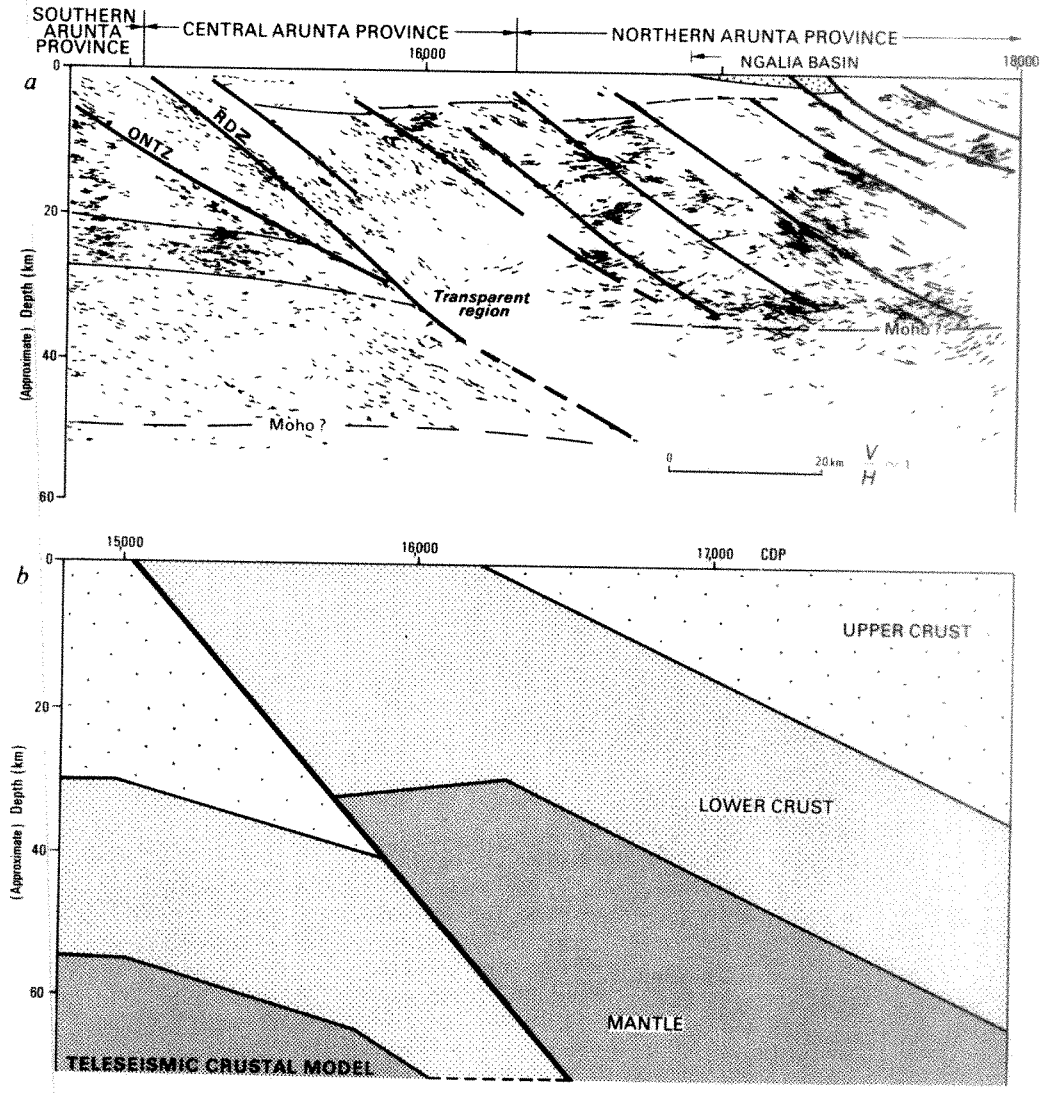

Fig. 4 Interpreted crustal structure of the Arunta Block. RDZ refers to the Redbank Deformed Zone and ONTZ to the Ormiston Nappe and Thrust Zone. *a*, Deep-seismic-reflection model. *b*, Teleseismic crustal model, based on the observed teleseismic travel-time data[1].

the Grenville Front of Canada[5] and, to a lesser degree, the Wind River Thrust of the USA[24], but it differs in that these latter structures do not exhibit the seismically transparent material on the lower part of the hanging wall. None of the Flannan, Outer Isles or Wind River Thrusts are associated with a major gravity anomaly. It is emphasized that the above remarks refer to the central part of the Arunta Block and Amadeus Basin, and that in an intracratonic environment the deformations along the eastern and western limits may differ in significant ways from this model.

Structural, metamorphic, and isotope data reveal that the Arunta Block has had a complex history. In particular, Rb/Sr and $^{40}Ar/^{39}Ar$ isotope data imply different evolutionary histories for the blocks north and south of the Redbank Thrust before 1,450 Myr and possibly until 1,100 Myr (ref. 9). The overall character of the seismic reflections changes across this thrust and this may be indicative of fundamental differences in crustal composition of the two regions, supporting the interpretation that the Redbank Thrust is a major crustal boundary. Furthermore, the isotope data and the metamorphic grade of the mylonites indicate that the granulites north of the Redbank Thrust were subjected to major uplift (~15 km) during the Alice Springs orogeny, particularly during the last phase of the Amadeus Basin formation which produced the upturned and overthrust northern margin (the Amadeus Homocline). Argon-loss data constrain this uplift at between 300–400 Myr, with the movements on the faults decreasing in age from north to south between the Redbank and Ormiston Thrusts[9].

Teleseismic travel-time residuals[10] favour models in which low-velocity crust is underthrust beneath overriding lower crust and mantle of the Central and Northern Arunta Provinces down to a depth in excess of 50 km (Fig. 4). The isotope evidence shows that a substantial part of this structure developed at a time leading up to and including the Alice Springs orogeny, producing a stacking or imbrication of the crust and the exposure of lower-crustal material north of the Redbank Zone. Displacement of the inferred granitic layer and the deflection of sub-horizontal reflectors against the fault or shear zones suggest that the faults north of the Redbank Thrust acted as 'lag' faults during the final stages of movements.

This model generates a number of questions. In particular, one can ask what are the driving forces that have produced this structure, how such a structure, obviously out of isostatic equilibrium, has been maintained for the past 300 Myr, and how these conclusions relate to other thick-skinned regions. The stress differences associated with the present structure are of the order of 100–150 MPa (ref. 10) and the stress fields associated with the forces that produced the structure must have been at least of this magnitude. The isostatic response is anisotropic. The east–west response is consistent with models of local or regional isostatic compensation, whereas the north–south response implies compressional in-plane stresses of the order mentioned[21]. The major movements on the Redbank Thrust before and during the Alice Springs orogeny indicate that compressional forces operated at this time, and the geological setting of central Australia indicates that this occurred within an intracratonic environment rather than at a plate margin. The timing of the Alice Springs orogeny coincides with the Kanimblan

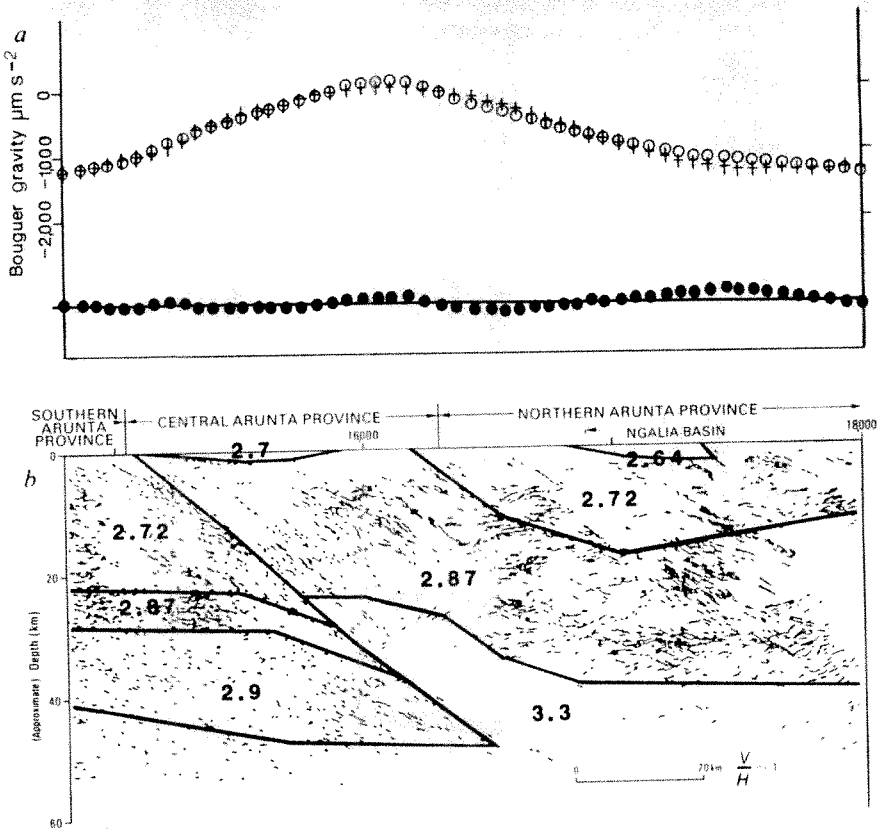

Fig. 5 *a*, Observed and computed gravity profiles along the deep seismic line. The computed profile is based on the interpreted deep-seismic-reflection model (*b*) for the Arunta Block. In *a*, crosses represent the observed profile, open circles represent the computed profile and filled circles represent the residual profile ± 150 μm s^{-2}. Numbers superimposed on *b* are the densities in g cm^{-3} assumed in the gravity calculations.

orogeny of eastern Autralia[25]; this suggests that the intracratonic movement may have been primarily the consequence of the lithosphere acting as a stress guide to forces operating at and shaping the plate margin some 1,000 km or more distant from the Redbank Zone[26]. The implication is that stress differences of 100 MPa and more can be transmitted by the lithosphere over distances equal to the dimensions of tectonic plates and that the evolution of intracratonic tectonic features such as basins may be driven by forces external to the area. Evidence for this can also be seen elsewhere, for example, in the relation between the tectonics of north-west Europe and the latest Cretaceous and Tertiary Alpine orogeny[27].

Once formed, stress relaxation would be expected to lead to isostatic rebound so that the area would reach some state of mechanical equilibrium. There is, however, surprisingly little evidence for major re-adjustment with time. The maximum gravity anomaly is associated with a very mild topographic low and the minimum anomaly is associated with a regional topographic high over the northern part of the basin, suggesting that some rebound has occurred[10]. At the time of the last orogenic event the area would have carried a significant topographic load created by the upthrust crust and by the synorogenic sediment loads deposited on the flanks of the thrust. A study of fission-track ages[28] and isotope evidence[9] points to a removal of up to 4 km of material from both the northern part of the Amadeus Basin and the southern part of the Arunta Block. Thus, immediately after the orogenic event, the region may have been close to isostatic equilibrium, but as erosion occurred the crust did not respond fully to the redistribution of surface loads. The probable explanation is that part of the north–south horizontal compressive force that led to the thrusting was still present after termination of the orogeny, at which time the lithosphere strengthened, locking the sub-surface structure and producing an increasingly regional response to the lateral variations in surface and internal loads[22]. We note that two major earthquake sequences occurred recently in central Australia, one to the south, in the Musgrave Block[29], and the other about 350 km north of the Ngalia Basin[30], both of which indicate that the present lithospheric stress field is one of north–south compression.

The authors wish to acknowledge the seismic team involved in the acquisition, Ivan Chertok for drafting the figures and Dr B. Drummond, M. Etheridge, H. McQueen and K. Gallagher for helpful discussions. B.R.G., R.D.S. and C.W. publish with the permission of the Director, Bureau of Mineral Resources, Geology and Geophysics, Canberra, Australia.

UNIQUE NEW JOURNAL

AVE £5

Through the **insight of leading scientists,** this unique publication provides an unrivalled, highly illustrated, overview of the current developments in **all aspects of modern Cell Biology.**

Each issue of the journal presents the developments during the past year in one or more major areas of Cell Biology.

This information is organized and presented in the following unique way ...

CELL BIOLOGY

The *best* way to find what you *most* need to know

Editors

NB Gilula

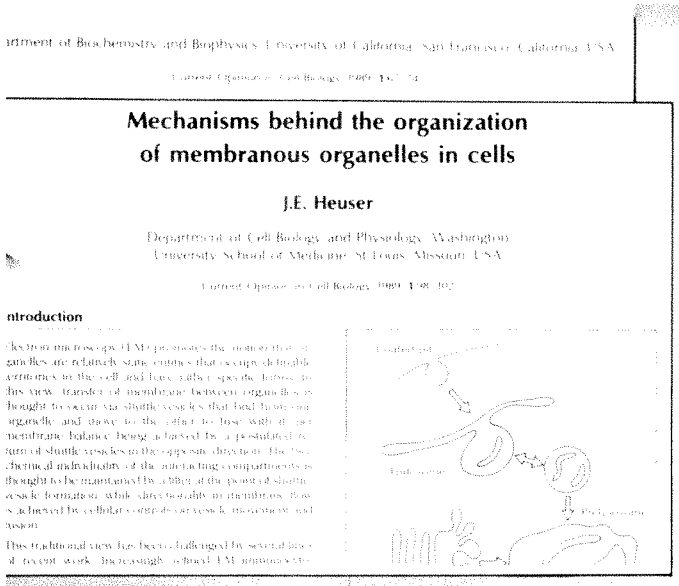
Editorial Board and Section Editors

In order to achieve systematic and comprehensive coverage, the Editors and Editorial Board divide the field of cell biology into a number of major sections and appoint leading authorities to act as Section Editors. The Editorial Board and Section Editors together compile a list of all journals relevant to cell biology. From these journals, cell biologists prepare a data base of all papers published under each section heading during the past year.

Table of Contents Volume 1 Number 1

Cytoplasm and cell motility



M. Kirschner and K. Weber	Cytoplasm and cell motility: overview
E. Mandelkow and E.M. Mandelkow	Microtubular structure and tubulin polymerization
D.W. Cleveland	Autoregulated control of tubulin synthesis in animal cells
J. Vandekerckhove	Structural principles of actin-binding proteins
J.S. Morrow	The spectrin membrane skeleton: emerging concepts
C.W. Lloyd	The plant cytoskeleton
R.M. Robson	Intermediate filaments
J.E. Segall and G. Gerisch	Genetic approaches to cytoskeleton function and the control of cell motility
D. Louvard	The function of the major cytoskeletal components of the brush border
U.W. Goodenough	Cilia, flagella and the basal apparatus
V.I. Gelfand	Cytoplasmic microtubular motors
T.J. Mitchison	Mitosis: basic concepts
J.V. Small	Microfilament-based motility in non-muscle cells

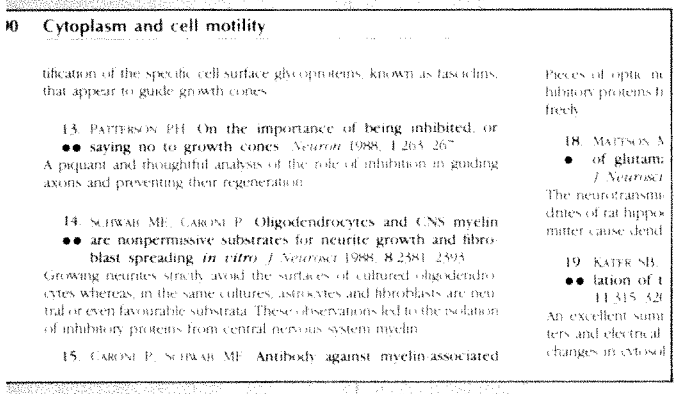
C.M. Wischik	Cell biology of the Alzheimer tangle

Current world literature

Cytoplasm and cell motility

Topics and Topic Reviewers

On the basis of this database the Section Editors divide each section into a number of topics ensuring that the content of the section is both comprehensive and topical.
The Section Editors then invite leading experts on each topic to act as topic reviewers. The reviewers are provided with a list of all papers relevant to their topic published over the past year.



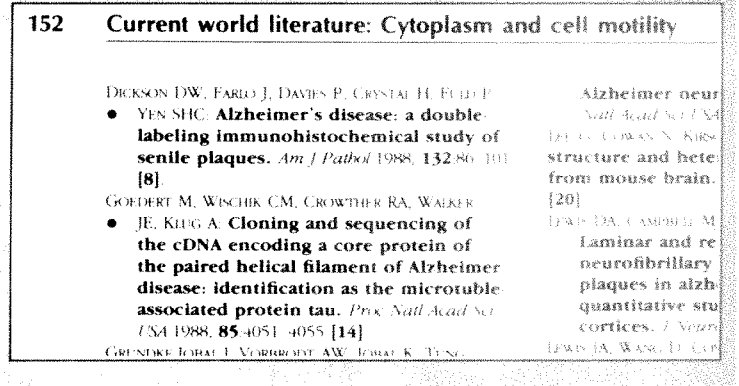
Mechanisms behind the organization of membranous organelles in cells

J.E. Heuser

Introduction

illustrated reviews summarizing the developments in their topic during the past year, which in their opinion have been of greatest interest and importance.

10 Cytoplasm and cell motility



Evaluated bibliographic selection

In addition to writing reviews, the reviewers select papers of special importance. They provide critical annotated references to those papers, and classify them on two levels:
(●) of interest,
(●●) of outstanding interest.

This combination of reviews and annotated references provides a unique insight and evaluation of developments in cell biology from those experts most intimately involved.

Current World Literature - A Unique Resource

At the end of each issue is a complete bibliographic listing of papers published in all journals scanned during the past year. Papers are listed alphabetically under sections and topics to provide a powerful and unique bibliographic resource.
In addition, a subject index and listing of all journals scanned is provided in each issue.

152 Current world literature: Cytoplasm and cell motility

No other publication offers the combination of

►Comprehensive, systematic and up-to-date review of modern cell biology

A unique bibliographic and quality assessment system comprising

►selected annotated references

►bibliography of the current world literature

USE THE ORDER FORM OVERLEAF TO RECEIVE AN INTRODUCTORY DISCOUNT!

A telomeric sequence in the RNA of *Tetrahymena* telomerase required for telomere repeat synthesis

Carol W. Greider* & Elizabeth H. Blackburn†

* Cold Spring Harbor Laboratory, PO Box 100, Cold Spring Harbor, New York 11724, USA
† Department of Molecular Biology, University of California, Berkeley, California 94720, USA

The telomerase enzyme of Tetrahymena *synthesizes repeats of the telomeric DNA sequence TTGGGG de novo in the absence of added template. The essential RNA component of this ribonucleoprotein enzyme has now been cloned and found to contain the sequence CAACCCCAA, which seems to be the template for the synthesis of TTGGGG repeats.*

NUCLEIC acid synthesis reactions are usually template directed. Exceptions include the reactions of terminal deoxynucleotidyl transferase, which adds any deoxynucleotide in a random order onto the 3′ end of a polynucleotide chain[1], poly(A) polymerase which adds rAMP residues to the 3′ end of RNA[2], and tRNA nucleotidyl transferase which adds the sequence CCA to the 3′ end of tRNAs[3]. In addition, we have discovered the enzyme telomerase which synthesizes tandem repeats of the telomeric DNA sequence TTGGGG to the 3′ end of telomeric primers without any added template[4,5].

Telomeres from such diverse organisms as ciliates, yeasts, plants, and mammals are made up of a variable number of tandemly repeated, simple (G+C)-rich sequences[6–12]. In all telomeres examined, there is a strand-specific sequence bias such that the G-rich strand always runs 5′ to 3′ towards the end of the chromosome. As the number of tandem repeats on the end of any given chromosome is variable[13,14], restriction fragments containing telomeres have a characteristic 'fuzzy' appearance in agarose gel electrophoresis. We have proposed that this length heterogeneity arises from a dynamic equilibrium established between the incomplete replication and/or degradation of the chromosome end and the *de novo* synthesis of telomeric sequences by telomerase[4,12–14].

The *Tetrahymena* telomerase extends the free TTGGGG-OH 3′ telomere strand by the addition of further TTGGGG repeats. Both the repeated sequence motif and the orientation of the G strand have been conserved throughout evolution, suggesting that telomerase-like enzymes may be found in all eukaryotes. The presence of telomerase would explain several observations about telomeres. First, when *Tetrahymena* or *Oxytricha* telomeric sequences are introduced into yeast, telomeric sequences characteristic of yeast are added to them[12,15,16]. Second, when trypanosomes or *Tetrahymena* are kept in continuous log-phase growth, there is a net increase in telomere length[13,17]. In *Tetrahymena* this increase involves all of the telomeres in the cell and is due to the addition of telomeric TTGGGG repeats[13,14]. Finally, telomeric sequences from a number of different organisms are maintained as perfect tandem repeats and do not diverge through recombination, unlike most simple repeated sequences in the nuclear genome[18–20] and mitochondrial telomeres[21,22]. This sequence maintenance can be explained by the continual synthesis of new perfect telomeric repeats.

Recently, telomerase activities have been isolated from the nuclei of both the hypotrichous ciliates *Oxytricha* and *Euplotes* (ref. 23; D. Shippen-Lentz and E. Blackburn, submitted). These enzymes synthesize repeats of the telomeric sequences of those organisms, TTTTGGGG, in an analogous way to the *Tetrahymena* telomerase. Together with the conserved structure of telomeres, these results further indicate that telomerase enzymes exist throughout eukaryotes.

We showed previously that the telomerase of *Tetrahymena* is a ribonucleoprotein (RNP) enzyme with essential RNA and protein components[5]. Because the reactions catalysed by many RNPs involve base pairing of the RNA components[24–28], the requirement of an RNA component in the *Tetrahymena* telomerase suggested that the synthesis of TTGGGG repeats might be specified by the RNA[5]. We report here the identification of the essential RNA component of telomerase and show that this RNA contains the sequence CAACCCCAA which could serve as a template for the synthesis of TTGGGG repeats.

Cloning and characterization of 159 RNA

We previously showed that small RNAs of approximately 159 bases and 80 bases co-purified with the telomerase RNP over five column purification steps[5]. Further purification of the telomerase over several other column series indicated that the RNA of about 159 bases (159 RNA) was the only one to reproducibly co-purify with the enzyme activity (data not shown). We directly sequenced the 159 RNA using both sequence-specific RNases and dideoxynucleotide primer extension techniques. Southern blot analysis of *Tetrahymena* macronuclear DNA, using oligonucleotide probes derived from the RNA sequence, indicated that there was a single gene for the 159 RNA in the macronuclear genome. A 2 kilobase (kb) *Hin*dIII fragment containing the gene was cloned from macronuclear DNA. The sequence of a 400-base region of the clone containing the 159 RNA coding sequence is shown in Fig. 1*a*. The most notable feature of the gene is the presence of the sequence 5′ CAACCCCAA 3′ from positions 43 to 51 within the coding region. This sequence could serve as a template for the addition of TTGGGG repeats *in vitro*.

Three ribonucleotide residues at positions 46, 47 and 48 in the 159 RNA were not cut by any of the ribonucleases used in the direct RNA sequencing, indicating that these bases might be modified, although primer extension by reverse transcriptase was unimpeded at these positions. Several different base modifications in tRNAs are known to interfere with ribonuclease cleavage[29]. Ribose 2′-*O* methylation inhibits both RNase and base hydrolysis of RNA by blocking the formation of the cyclic phosphate intermediate[30]. As the base hydrolysis ladder was complete at these positions in the telomerase RNA (data not shown), this type of modification can be ruled out. Both secondary structure modelling of the telomerase RNA (I. Tinoco, personal communication) and data presented below indicate that this region of the RNA is not in a tightly base-paired structure; hence structural interference was probably not responsible for the inability of RNases to cut at these positions. Although the nature of these possible base modifications is not known, it is intriguing that they lie within the CAACCCCAA sequence.

Several features of the 159 RNA gene suggest that it is transcribed by RNA polymerase III. First, the length of the 159 RNA is heterogeneous. Using high-resolution polyacrylamide gel electrophoresis we separated a cluster of four bands and sequenced the two prominent species in the middle. These two species differed only in the number of U residues at the 3′ end. In the sequence of the cloned gene this 3′ end of the RNA falls

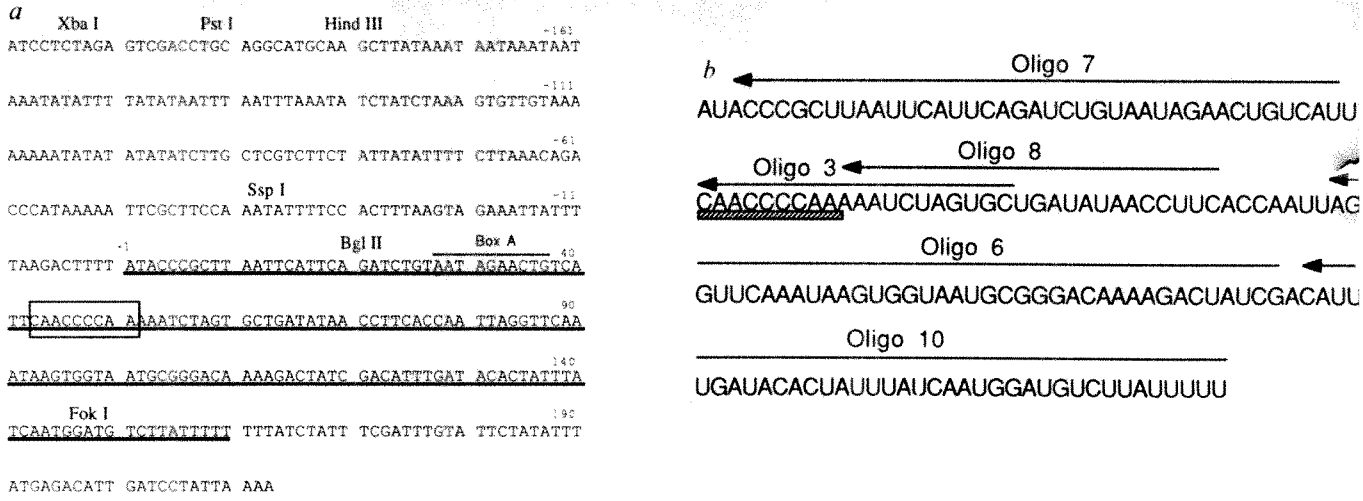

Fig. 1 *a*, Sequence of the telomerase RNA gene. The first 30 nucleotides of the pUC119 polylinker up to the *Hin*dIII site used for cloning are shown for orientation along with 370 bases of the non-template strand of the telomerase RNA gene. The region corresponding to the RNA is underlined. The start site of transcription as determined by dideoxy primer extension sequencing is labelled +1 and the 3′ end of the RNA as determined by direct RNA sequencing is shown within the run of eight T residues near position 160. All of the six-base recognition restriction enzymes which cut in the *Tetrahymena* DNA are shown above their recognition sites. A region of similarity with the consensus Box A for polymerase III genes is shown at positions 28–37. The sequence CAACCCCAA within the RNA gene which may provide the template for the addition of TTGGGG sequences *in vitro* is shown in the box at position 43. *b*, The oligonucleotides (oligos) used for cloning, sequencing and RNase H experiments are shown above the telomerase RNA regions to which they hybridize. The region of the RNA containing the potential template is underlined with a hatched bar. Oligonucleotides 1–6 were made using the sequence information obtained by partial enzymatic RNase sequencing. Oligonucleotides 1, 2, 4 and 5 were shown to contain significant mismatches with the correct sequence obtained by DNA sequence analysis. Oligonucleotides 7, 8 and 10 were synthesized using DNA sequence information. Only the oligonucleotides that were shown to hybridize to the 159 RNA are shown. The sequence and name of all the oligonucleotides used throughout this paper are listed from 5′ to 3′. Oligo 2, TTCTGTTGCAAAATCTGAATGAAT. Oligo 3, GCACTAGATTTTTGGGGTTG. Oligo 5, TTGTTTGAACCTGATT-GTGAAGGTT. Oligo 6, CGATGGTCTTTTGTCCCGCATTGCCACTTGTTTGAACCT. Oligo 7, ATGACAGTTCTATTACAGATCTGAAT-GAATGAATTAAGCGGGT. Oligo 8, GAAGGTTATCAGCACTAGATTT. Oligo 10, AAAAATAAGACATCCATTGATAAATAGT-GTAT-CAAATG.

Methods. Telomerase S100 preparation (60 ml) was fractionated over a sizing column, heparin agarose, and spermine agarose[5]. An aliquot of the active fraction (30 ml) was digested with proteinase K, phenol extracted and ethanol precipitated; half of the RNA was 3′ end-labelled with [^{32}P] pCp using RNA ligase and half was treated with calf intestinal phosphatase, phenol extracted and labelled with [γ-^{32}p]ATP using polynucleotide kinase. The labelled RNA was run on an 80 cm 15% acrylamide/7M urea gel for 21 hours at 3,500 V. The two major bands corresponding to the 159 and 160 species of RNA were cut out, eluted from the acrylamide and partial enzymatic RNA sequencing was done. The sequence obtained from the 5′ and 3′ labelled RNAs overlapped by 50 bases. Thus the entire sequence was obtained except for a few bases where the sequence data from both 5′ and 3′ labelled RNA was unreadable possibly due to RNA base modifications (see text). Using this sequence information, oligonucleotide 6 was synthesized and used as a primer for dideoxy primer extension RNA sequencing. Eighty-one nucleotides of sequence were obtained and oligonucleotides were then synthesized and used for cloning of genomic copy of the RNA. *Tetrahymena* macronuclear DNA was cut with *Hin*dIII and size fractionated on a 0.8% agarose gel. The region around 2.0 kb was cut out and electroeluted. This DNA was ligated into *Hin*dIII-cut pUC119 plasmid and transformed into DH5α F′. 30,000 transformants were obtained: of these 10,000 were screened by colony hybridization. Replica plates were made of the transformation plates, and duplicate colony lifts onto nitrocellulose were made. The duplicate filters were hybridized in 6x SSC, 4x Denhardts and 0.1% SDS with either oligonucleotide 3 or oligonucleotide 6 at 55 °C for 15 hours. The filters were then washed three times at room temperature in 3x SSC 0.1% SDS for 10 min, and then in 3x SSC 0.1% SDS at 55 °C for 10 min. One clone was obtained which hybridized to both oligonucleotides. The clone was sequenced using double stranded dideoxy sequencing (USB-sequenase kit) with the reverse universal primer and an oligonucleotide internal to the RNA gene as primers.

in a stretch of eight T residues. These properties are typical of RNA polymerase III transcription termination[31]. Second, we were able to label the 5′ end of RNA with [γ-^{32}P]ATP and polynucleotide kinase after treatment with phosphatase, indicat- 5′ end of the 159 RNA was not capped (data not shown). Third, there is a region of similarity to the box A consensus RRYNNARYGG[32] beginning 30 nucleotides downstream of the 5′ end of the 159 RNA.

d(TTGGGG)$_4$ elongation interference

We used RNase H inactivation to establish whether the 159 RNA was an essential component of telomerase. This technique has been used to identify essential RNAs for a variety of RNPs[27,28,33–36]. Telomerase was preincubated with antisense oligonucleotides (Fig. 1*b*) in the presence or absence of RNase H. After the preincubation, the primer d(TTGGGG)$_4$ oligonu-cleotide was added along with [α-^{32}P] dGTP, dTTP and reaction buffer, and the ability of telomerase to synthesize TTGGGG repeats was assayed (Fig. 2). Oligonucleotides 2, 5, 6, 7 and 10, which are complementary to the 159 RNA, had no effect on telomerase activity in either the presence or absence of RNase H. However, oligonucleotide 3 strongly inhibited telomerase activity in either the presence or absence of RNase H, and preincubation with oligonucleotide 8 resulted in an upward shift in the characteristic six-base banding pattern, suggesting this antisense oligonucleotide was itself efficiently priming repeat addition (Fig. 2; see lanes 17–20). In the absence of added RNase H the 159 RNA was intact, indicating that endogenous RNase H was not responsible for the inhibition of telomerase by oligonucleotide 3 (Fig. 4 and data not shown). Although in this initial experiment the effects of RNase H addition were not definitive, the observations that oligonucleotides 3 and 8, which hybridize across, and near to, the CAACCCCAA sequence respectively, specifically affected telomerase activity suggested the 159 RNA is involved in telomerase activity.

Northern analysis of RNA extracted from active telomerase fractions probed with oligonucleotides 3 and 8, showed only one band at 159 nucleotides (data not shown). Thus, these oligonucleotides do not share extensive sequence complementarity with other RNAs in the enzyme fractions used throughout this work.

The inhibition of telomerase activity by preincubation with

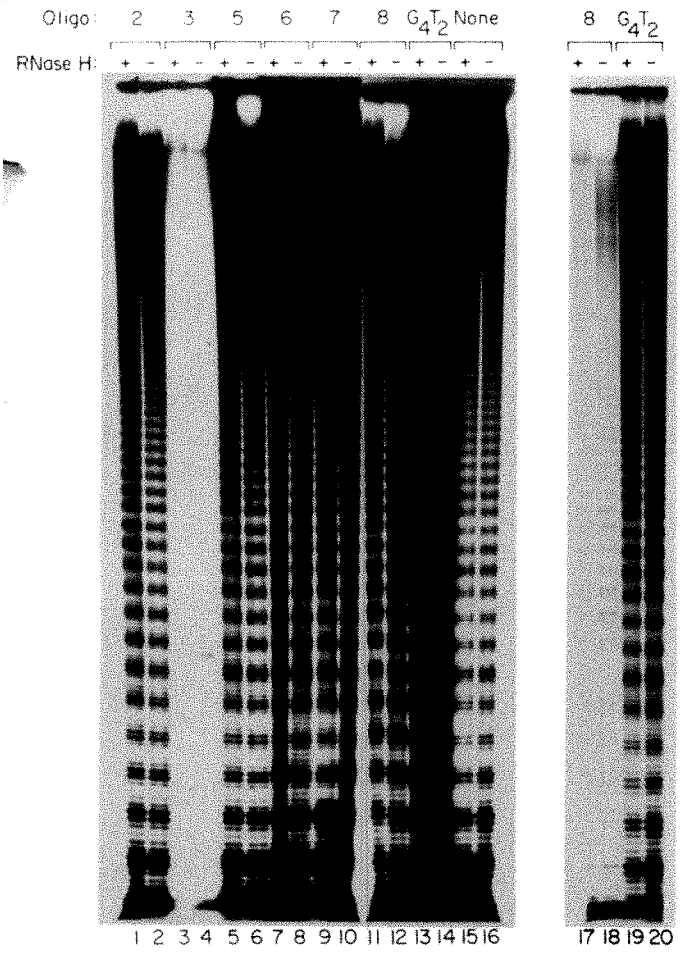

Fig. 2 Treatment of telomerase with antisense oligonucleotides and RNase H. The oligonucleotides indicated were preincubated with telomerase in the presence (+) or absence (−) of RNase H. The ability of telomerase to elongate added d(TTGGGG)$_4$ primer was then assayed. The oligonucleotides added in the preincubation are indicated above the lanes. G_4T_2 is d(TTGGGG)$_4$. Lanes 17–20 show a lighter exposure of lanes 11–14 to indicate better the upward shift in the banding pattern when oligonucleotide 8 is included in the preincubation.

Methods. Telomerase which had been purified over a sizing column and heparin agarose was used[5]. Antisense oligonucleotide (2 μl) at 0.4 μg μl^{-1} was added to 10 μl of telomerase, followed by either 2 μl of RNase H at 2U μl^{-1} (BRL) or 2 μl of TMG + 0.1 M NaCl (TMG, 10 mM Tris *p*H 8.0, 1 mM $MgCl_2$, 10% glycerol) were added. The samples were preincubated at room temperature for 30 min and then 6 μl of TMG + 0.1 M NaCl and 20 μl of 2x reaction mix was added. The 2x reaction mix contained: 0.1 μg d(TTGGGG)$_4$, 200 μM dTTP, 200 mM NaOAc, 100 mM Tris *p*H 8.0, 10 μCi [^{32}P]dGTP at 400 Ci mmol^{-1}. Reactions were carried out at 30 °C for 60 min, the mix then phenol extracted, ethanol precipitated and run on a 6% polyacrylamide sequencing gel.

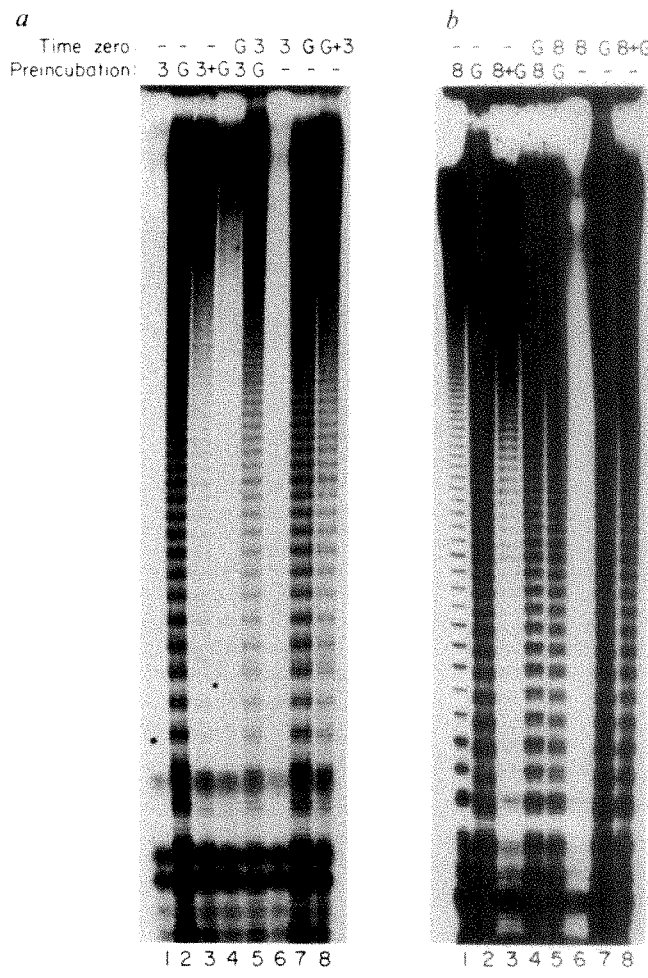

Fig. 3 *a*, Competition between oligonucleotide 3 and d(TTGGGG)$_4$. Telomerase was preincubated at room temperature with the oligonucleotides indicated above the lanes. G is d(TTGGGG)$_4$. At time zero, reaction buffer was added and the reaction was carried out as described in the Fig. 2 legend. The oligonucleotides indicated were added at time zero. *b*, Competition between oligonucleotide 8 and d(TTGGGG)$_4$. The oligonucleotides indicated above the lanes were added in the preincubation. G is d(TTGGGG)$_4$. At time zero the oligonucleotides indicated were added. Darker exposure of the autoradiogram showed a banding pattern in lane 6 similar to that in lane 1.

Methods. 20 μl of telomerase purified as described in the Fig. 2 legend was preincubated with 1 μl of each oligonucleotide at 0.4 μg μl^{-1} or with 1 μl of water as indicated. Preincubation was at room temperature for 30 min. At time zero 20 μl of 2x reaction mix containing 1 μl of the appropriate oligonucleotides or no oligonucleotide was added and the standard activity assay was carried out (see Fig. 2 and ref. 5).

oligonucleotide 3 even in the absence of RNase H suggested that this oligonucleotide might interfere with the access of d(TTGGGG)$_4$ to telomerase. To test for specific inhibition, we reversed the order of addition of the two oligonucleotides. When oligonucleotide 3 was used in the preincubation and the d(TTGGGG)$_4$ was added at the beginning of the elongation reaction (referred to as time zero) there was the same inhibition as in Fig. 2. If d(TTGGGG)$_4$ was added first to the preincubation and then oligonucleotide 3 was added at time zero, there was no inhibition however. When oligonucleotide 3 and d(TTGGGG)$_4$ were added together, an intermediate level of inhibition was seen (Fig. 3*a*). Thus, inhibition by oligonucleotide 3 is a specific effect and its properties are consistent with competition with d(TTGGGG)$_4$.

As oligonucleotide 3 contains the sequence TTGGGGTTG at its 3′ end, its interference with d(TTGGGG)$_4$ elongation could simply be due to its sequence similarity with the d(TTGGGG)$_4$ primer. We also found that oligonucleotide 8, which does not contain any TTGGGG sequence, is itself efficiently elongated by telomerase (Fig. 3*b*). The addition of oligonucleotide 8 alone resulted in the synthesis of a repeat pattern that was shifted upward relative to the pattern primed by d(TTGGGG)$_4$. The repeat pattern visualized by this gel assay is dependent on the sequence and length of the input primer oligonucleotide[5]. Thus, the upward shift in the banding pattern distinguishes the products primed by addition to oligonucleotide 8 from those primed by d(TTGGGG)$_4$. When oligonucleotide 8 was added in the preincubation and d(TTGGGG)$_4$ was added at time zero, the main products had the oligonucleotide 8-primed pattern. In contrast, when the d(TTGGGG)$_4$ oligonucleotide was added

first and oligonucleotide 8 was added at time zero, the characteristic d(TTGGGG)$_4$ primed pattern was seen. Simultaneous addition of the two oligonucleotides, either in the preincubation or at time zero, resulted in a mixture of the two patterns indicating that both oligonucleotides were being elongated under these conditions. As oligonucleotide 8 was the only oligonucleotide with a non-telomeric sequence, of 14 tested, that was efficiently elongated by telomerase (see also ref. 5; data not shown), we suggest that the base pairing of oligonucleotide 8 to the 159 RNA adjacent to the CAACCCCAA sequence allows its elongation by telomerase.

Inactivation by cleavage of 159 RNA

The interaction of oligonucleotides 3 and 8 with telomerase *in vitro* suggested that the 159 RNA is a component of telomerase. To investigate further the requirement for this RNA, we sought conditions under which the effects of cleavage of the 159 RNA could be assayed. In RNase H inactivation experiments oligonucleotides 2, 6, 7 and 10, complementary to the 159 RNA, did not inhibit telomerase activity or cause cleavage of the 159 RNA by RNase H (Fig. 2 and data not shown). To assay the effects of oligonucleotide 3 and RNase H, we had first to relieve the inhibition by oligonucleotide 3. We pelleted the telomerase in an ultracentrifuge after preincubation with the test oligonucleotide and RNase H. The enzyme activity of each resuspended pellet was then assayed (Fig. 4*a*) and the RNA examined for evidence of 159 RNA cleavage (Fig. 4*b*). There was no effect on either telomerase activity or the 159 RNA after preincubation with oligonucleotide 7 in either the presence or absence of RNase H. After preincubation and subsequent removal of oligonucleotide 3 in the absence of RNase H, both telomerase activity and the 159 RNA were intact. Preincubation with oligonucleotide 3 in the presence of RNase H however, inhibited telomerase activity and caused cleavage of the 159 RNA. In a separate experiment, we used primer extension to map the sites at which RNase H cuts in the telomerase RNP (Fig. 5). Although in this experiment cutting by RNase H was incomplete, oligonucleotide 3 directed cutting at several positions along its region of complementarity to the 159 RNA, including nucleotides in the CAACCCCAA sequence.

Oligonucleotide 8 also directs RNase H cutting of the 159 RNA; cutting with this oligonucleotide, even when apparently complete, did not however inactivate the telomerase (data not shown). Oligonucleotide 8 cannot base pair in the CAACCCCAA sequence and accordingly all of the cut sites mapped by primer extension are 3′ to the potential template sequence (Fig. 5). Although the ability of telomerase to function after oligonucleotide 8-directed cleavage of the RNA was surprising, it is not unprecedented. The signal recognition particle retains its microsomal translocation activity after micrococcal nuclease digestion which removes up to 150 nucleotides of the 300 nucleotides in the essential 7SL RNA[37,38]. In addition, the 25S rRNA from mature ribosomes of insects is found naturally cleaved into two halves with some sequences missing[39,40]. Furthermore, in *Crithidia*, the 25S RNA is found cleaved into five pieces[41] and in *Chlamydomonas* both the large and small rRNAs are processed into multiple pieces that are held together by intermolecular base pairing[42]. Finally, deletion and replacement analysis of the essential RNA component of the yeast U2 small nuclear RNP has shown that not all regions of this RNA are essential for activity *in vivo*[43]. The specificity of telomerase inactivation by oligonucleotide 3-directed cutting within the CAACCCCAA sequence, compared with the cutting near this sequence directed by oligonucleotide 8, is evidence for the important nature of the CAACCCCAA sequence in telomerase activity.

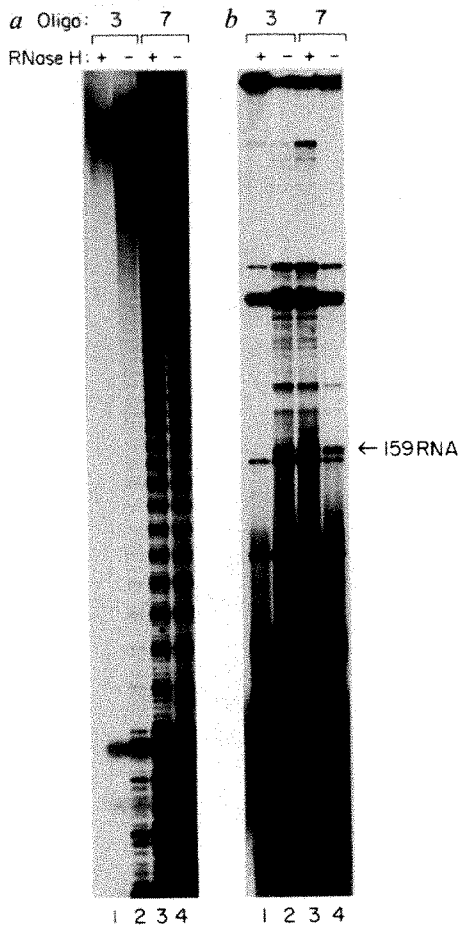

Fig. 4 *a*, The activity of telomerase which had been pretreated with various oligonucleotides in the presence or absence of RNase H and then pelleted in a ultracentrifuge to remove excess oligonucleotide. RNase H was added during the preincubation to the reactions shown in lanes 1 and 3, but not in lanes 2 and 4. The oligonucleotides used in the preincubation are indicated above the lanes. The low level of activity seen in lane 2 relative to lanes 3 and 4 is due to the inhibitory effects of residual oligonucleotide 3 in these fractions. The dark material seen at the top of the gel in lane 1 is due to labelling of high relative molecular mass nucleic acid by some enzyme in the partial purified fraction. More highly purified telomerase fractions do not show this label accumulation. *b*, RNA from the pellets in *a* was extracted, 3′ end-labelled with [^{32}P] pCp and run on a sequencing gel. The lanes are as in *a*. The position of the 159-base telomerase RNA is indicated with an arrow.

Methods. 200 μl of telomerase purified as described in the Fig. 2 legend was preincubated with 6 μl of the appropriate oligonucleotide at 1 μg μl^{-1} in the presence or absence of 5 μl of RNase H at 2U ul^{-1}. Preincubation was at room temperature for 15 min. The extracts were then transferred to Beckman microfuge tubes and spun at 75,000 r.p.m. in a Beckman TLA-100.3 rotor at 4 °C for 3 hours. The supernatant was removed carefully and the pellet was resuspended in 100 μl of TMG+0.1 M NaCl. 20 μl was immediately assayed in the standard activity assay (see Fig. 2 and ref. 5). To the remaining 80 μl, 10 μg of proteinase K was added and the mix was incubated at room temperature for 15 min. The preparation was then phenol-extracted, ethanol-precipitated, 3′ end-labelled with pCp as described[5] and run out on a 6% polyacrylamide/7 M urea sequencing gel.

Discussion

CAACCCCAA sequence may provide a template for TTGGGG repeat synthesis. We have identified and cloned the gene for an essential RNA component of telomerase. Several lines o evidence indicate that the synthesis of TTGGGG repeats i directed by an RNA template. First, the only RNA which repro ducibly co-purified over numerous columns contains th sequence CAACCCCAA. Second, oligonucleotide 8 whose 3 end base pairs just downstream from the CAACCCCA sequence is efficiently elongated by telomerase, whereas all othe

non-telomeric sequences are not. Third, oligonucleotide 3, which is complementary to the telomerase RNA sequences up to and including the CAACCCCAA sequence, inhibits telomerase activity. Finally, cleavage by oligonucleotide 3 and RNase H within the CAACCCCAA sequence specifically inactivates telomerase activity. These observations suggest that the CAACCCCAA sequence of the telomerase RNA is in the active site of the RNP and that this sequence provides a template for synthesis of TTGGGG repeats.

Primer elongation by telomerase can result from two modes of primer recognition. Preincubation of telomerase with $d(TTGGGG)_4$ and RNase H did not inhibit enzyme activity (Fig. 2) or result in cleavage of the telomerase RNA, whereas there was RNA cleavage when $d(TTGGGG)_4$ was incubated with naked telomerase RNA and RNase H (data not shown). In contrast, base pairing of both oligonucleotide 3 and oligonucleotide 8 with the telomerase RNA in the intact RNP can direct cleavage by RNase H. Cleavage by RNase H can occur with as few as six base pairs of DNA-RNA duplex[44]. Thus, the base-pairing interaction of oligonucleotides 3 and 8 with the telomerase RNP must be distinct from the way in which $d(TTGGGG)_4$ interacts with the RNP during the preincubation. This difference could be due to an alteration in the RNP structure induced by oligonucleotides 3 and 8, or it may reflect a real distinction between telomerase recognition and elongation. The initial recognition of telomeric primers may not involve the CAACCCCAA sequence of the RNA. This is consistent with our earlier observations that G-rich oligonucleotides with differing primary sequences corresponding to the telomeric sequence of a number of species, as well as synthetic telomere-like sequences, all efficiently prime repeat addition by telomerase[5,45]. Together, these data indicate that a primer can be delivered to the active site in two ways; telomeric G-rich sequence oligonucleotides are specifically recognized, possibly by their unusual secondary structural features[46], whereas some oligonucleotides complementary to the 159 RNA (like 3 and 8) can be positioned in the active site by base hybridization.

The elongation translocation mechanism. When oligonucleotide 8 was preincubated with telomerase and $d(TTGGGG)_4$ was added at time zero, the oligonucleotide 8-primed pattern was seen in the products, indicating that the elongation reaction is processive. This, together with the evidence that hundreds of repeats of TTGGGG are synthesized on the input primer, and that there are one and a half repeats of the template sequence, indicate that an elongation-translocation mechanism operates to synthesize many tandem repeats. Previous work showed that the sequence at the 3′ end of a telomeric primer is recognized by telomerase in the elongation reaction. A primer ending in TTGGGG 3′ is distinguished from those ending in TTGGG 3′, GGGGTT 3′ or TTGG 3′[5,45] and each primer is correctly filled out to complete the last TTGGGG sequence before further repeats are added. These data could be explained by the mechanism outlined in Fig. 6. After primer recognition, the most 3′ nucleotides of the primer are hybridized to the 3′ portion of the CAACCCCAA sequence and the primer is filled out to complete the last full hexanucleotide repeat. Translocation then repositions the primer so that its most 3′ nucleotides are again hybridized ready for elongation.

Such an elongation-translocation mechanism could contribute to the strong six-base periodicity of the *in vitro* addition reaction. Earlier work showed that varying the relative concentrations of dTTP and dGTP in the reaction could change the intensity of the bands in the *in vitro* synthesized banding pattern[4]. This dependance on nucleotide precursor concentrations is also seen for the *Oxytricha* and *Euplotes* enzymes (ref. 23 and D. Shippen-Lentz and E. Blackburn, submitted). Pausing upon the addition of dTTP, as well as primer translocation, may contribute to the six base periodicity in the *in vitro* reaction products. Depending on the nucleotide concentration used, either two or three strong stops are seen in the elongation pattern using $(TTGGGG)_4$ as

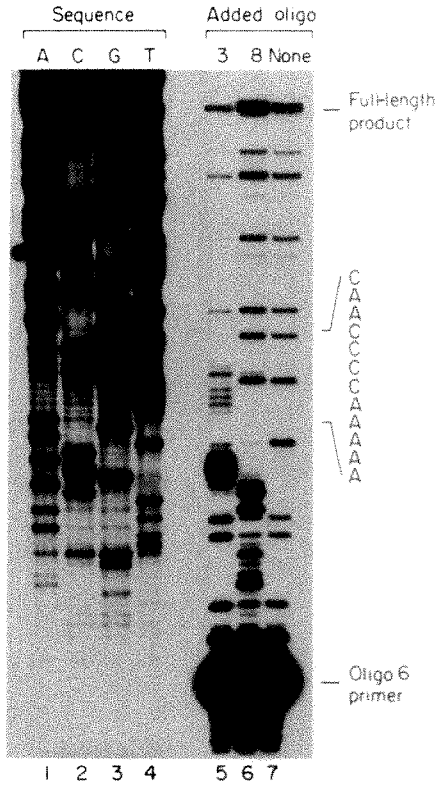

Fig. 5 Primer extension analysis of telomerase RNA cut with RNase H. Lanes 1–4, the sequencing ladder marker using oligonucleotide 6 as a primer. Lanes 5–7, the extension products from [^{32}P] oligonucleotide 6 on RNA extracted from telomerase fractions after treatment with RNase H and the oligonucleotides indicated above the lanes. The bands which appear in all of the lanes including lane 7, where no oligo was added, were probably due to the secondary structure of the 159 RNA. The full-length primer extension product is seen in all of the lanes because the cutting by RNase H in this experiment was not complete. The region corresponding to the CAACCCCAA sequence is indicated.

Methods. 400 μl of telomerase purified over a sizing column and heparin agarose, were incubated with 10 μl of the indicated oligonucleotide and 10 μl of RNase H (2U μl^{-1}) at room temperature for 30 min. 40 μl of a 10% SDS +100 mM EDTA solution and 10 μg of proteinase K were added. The mix was incubated at room temperature for 20 min and then the RNA was phenol extracted and ethanol precipitated after the addition of 5 μg of carrier tRNA. The pellet was resuspended in 6 μl of 125 mM KCl and 5 mM Tris *p*H 8.3. To 3 μl of RNA, 1 μl of [^{32}P] oligo 6 containing 0.05 μg was added and each mix was incubated at 65 °C for 5 min. The annealing reactions were then transferred to 42 °C for 1 hour. To each reaction 6 μl of elongation mix was added. The elongation mix contained 2 μl 5x reverse transcriptase buffer, 1 μl each dNTP at 2.5 mM, 1 μl avian myeloblastosis virus (AMV) reverse transcriptase (Life Sciences), 2 μl DEP-water. The elongation was carried out at 52 °C for 30 min. Sequencing loading dye (4 μl) was then added and 4 μl of each sample was loaded onto a 6% polyacrylamide sequencing gel. The sequencing markers were produced using oligonucleotide 6 as a primer following the procedure for supercoiled DNA sequencing using the Sequenase kit (USB).

the primer. The two strong stops correspond to the two T residues in the repeat[4] whereas the three stops correspond to the addition of the nucleotides TTG (data not shown). This pausing pattern is consistent with the model presented in Fig. 6 for elongation and translocation.

Implications of the internal RNA template. The specification of TTGGGG repeat addition by an internal template is analogous to the utilization of the internal binding site as a template in the reactions catalysed by the *Tetrahymena* intron ribozyme. This ribozyme has been shown to catalyse self splicing, *trans*-splicing, RNA endonuclease and RNA polymerase reactions[47–52]. In all of these reactions a sequence internal to the

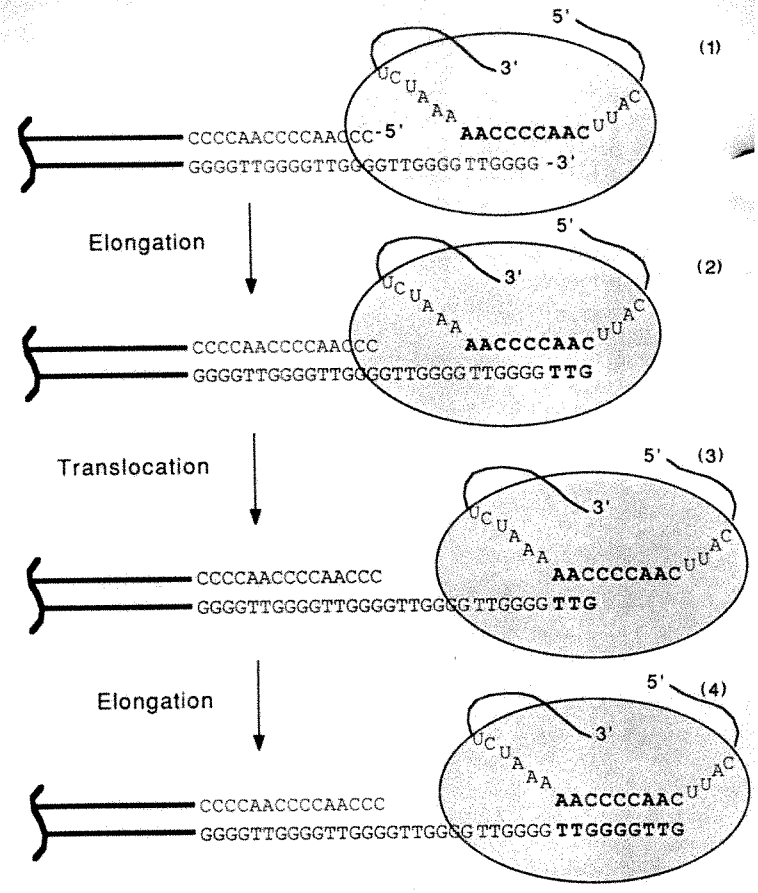

Fig. 6 Model for elongation of telomeres by telomerase. The *Tetrahymena* telomere is shown containing a 13-base overhanging TTGGGG strand[54]. (1) After recognition of the TTGGGG strand by telomerase, the 3′ most nucleotides are hybridized to the CAACCCCAA sequence in the RNA. (2) The sequence TTG is then added one nucleotide at a time[4]. (3) Translocation then repositions the 3′ end of the TTGGGG strand such that the 3′ most TTG nucleotides are hybridized to the RNA component of telomerase. (4) Elongation occurs again, copying the template sequence to complete the TTGGGGTTG sequence. This mechanism explains how oligonucleotides with 3′ ends terminating at any nucleotide within the sequence TTGGGG are correctly elongated to yield perfect tandem repeats of $(TTGGGG)_n$ (ref. 5).

ribozyme interacts with a substrate through Watson–Crick base pairing. Mutations in this internal binding site alter the substrate specificity of the ribozyme[47]. By analogy, it is predicted that changing the sequence of the internal template of telomerase would result in synthesis of telomeric repeats of that altered sequence. Whether the analogy between the telomerase and the intron ribozyme of *Tetrahymena* extends to include catalysis by RNA alone is a question which we can now begin to address.

DNA replication and RNA transcription represent conventional nucleic acid synthesis reactions directed by an external template. Terminal deoxynucleotidyl transferase, poly(A) polymerase and tRNA nucleotidyl transferase represent completely template-independent mechanisms of nucleic acid synthesis. In contrast to both of these types of polymerases, the *Tetrahymena* intron ribozyme and telomerase represent a new class of polymerase which is characterized by containing a template sequence that is an integral component of the polymerase itself. Although many RNPs, as well as the *Tetrahymena* ribozyme, use base pairing of their RNA components with other RNAs to determine reaction specificity[24–28,53], the telomerase enzyme is unique among eukaryotic RNPs in that it uses an RNA template for DNA synthesis.

The synthesis of DNA using an RNA template may be a very ancient process. Telomerase enzymes with RNA components may be relics that have descended from an ancestral type of DNA polymerase whose action was based on an internal RNA template. In this model, the primitive DNA polymerase was replaced in evolution by the current protein-based DNA polymerases and reverse transcriptases which use exogenous templates, whereas telomerase retained the endogenous template and was used by eukaryotes for telomere maintenance.

We thank Bruce Futcher, Bruce Stillman and Kim Arndt for useful discussions and critical reading of the manuscript, and the NIH and Cold Spring Harbor Laboratory for support.

Is N44C a fossil X-ray ionized nebula?

Manfred W. Pakull & Christian Motch

Observatoire de Besançon, Unité Associée 040 389 du CNRS, Université de Franche-Comté, 25044 Besançon Cedex, France

Long-slit spectroscopic CCD observations of the H II region N44C (refs 1–3) in the Large Magellanic Cloud and its central hot, massive star[2,3] show that the stellar temperature is far too low to account for the high excitation of the nebula. In particular the strong nebular He II 4686-Å recombination radiation, which is absent in normal H II regions, cannot be understood in terms of ionization by the stellar ultraviolet flux. Here we propose an alternative interpretation in terms of a (fossil) X-ray photo-ionized nebula resembling the recently discovered He III region around the luminous X-ray binary LMC X-1 (ref. 4). In this picture the presently extinct X-ray source that has been responsible for the high ionization in N44C could well be identical with the transient LMC X-5 (refs 5, 6). From photon-counting arguments and recombination timescales of the interstellar plasma we find that less than 100 years ago the X-ray luminosity should have been comparable with that of the most luminous X-ray binaries (a few $\times 10^{38}$ erg s^{-1}). This hypothesis can be tested by future observations.

Among the most conspicuous differences that distinguish emission line spectra of H II regions from those of the generally more highly photo-ionized planetary nebulae is the absence, in the former, of the He II 4,686-Å recombination line, because even the hottest known massive stars (O stars) radiate only negligible amounts of photons more energetic than 4 Rydbergs (54.4 eV), which are of sufficient energy to ionize helium completely[7,8] (see below). A notable exception is the nebula N44C (NGC1936) in the Large Magellanic Cloud (LMC), which was reported[1] to exhibit an unusually high-excitation planetary-nebula-type spectrum that includes strong He II 4,686-Å recombination radiation ($I_{4,686}/I_{H\beta} = 0.07$). Subsequently[2], this region was studied by narrow-band photographic imaging of Hα and [O III] 5,007-Å emission surrounding a central star, which was proposed as the cause of the ionization.

These investigations have not been followed up until recently, when the nebular He II 4,686-Å emission was rediscovered[3] and an effective stellar temperature of 70,000 K was derived from the nebular recombination-line flux and the optical brightness ($V = 14.6$; K. Reinsch, personal communication) of the central star (star 2), using the Zanstra method. Luminous stars with such high temperatures have so far not been detected (the earliest spectral types, O3, correspond to $T_{\rm eff} = 45{,}000$–$53{,}000$ K)[9,10], but they are nevertheless predicted to exist during late (helium-burning) phases in the evolution of very massive stars[11–14]. Because of strong mass loss in a stellar wind, however, the surfaces of stars initially more massive than ~40 $M_\odot$ are expected to become strongly depleted in hydrogen and should appear as hot Wolf–Rayet (WR) stars[11–13]. Whereas the issue of WR-star temperatures is a matter of current debate (see ref. 15 and references therein), we note that some WR stars indeed emit a luminous He^+ Lyman continuum capable of photo-ionizing large He III regions. Examples of such systems are the galactic nebula G2.4+1.4 around the WO1 star LSS4368 (ref. 32) and part of the nebula N76A in the Small Magellanic Cloud, which is ionized by the WN star AB7 (M.W.P. *et al.*, manuscript in preparation). Because of heavy contamination by the nebular emission lines of N44C, the previously reported[3] spectrum of star 2 does not provide good indications of photospheric temperature and hydrogen abundance; the lack of broad emission-line features, however, already excludes a WR-type nature. Here we report results that do not support the suggestion of a very high surface temperature, and we suggest an alternative explanation for the high degree of ionization in N44C in terms of a fossil X-ray ionized nebula.

During four consecutive nights in January 1987 we carried out long-slit spectroscopic observations of N44C and its central star using the B&C spectrograph on the ESO 3.6-m telescope with a 520×320-pixel (30 μm size) RCA CCD detector and a spectral full-width-at-half-maximum (FWHM) resolution of 5.5 Å (1.6 pixel). Several different slit orientations were chosen to cover as much of the emission-line region as possible. The intensities of several diagnostic nebular lines were extracted as a function of position along the slit, and background stellar and nebular continuum emission at nearby wavelengths were subtracted (see ref. 4 for method). In these intensity histograms stellar absorption/emission lines appear as corresponding features with a width determined by the seeing profile during the observations (1.5–2.5 arcsec FWHM). Figure 1 illustrates the strong concentration of the H I and He I nebular intensity and the increase in helium and oxygen ionization towards the central star 2. The mean extent of the He III region, as measured from the He II 4,686-Å recombination line, amounts to 18 arcsec, corresponding to 4.5 pc at the distance of the LMC, but this emission can be traced even to 35 arcsec (9 pc) in a radial filament southwards of the centre. Unresolved dips are clearly present in all H-Balmer-line and He I 4,471-Å intensity histograms (corresponding to different slit orientations) at the position of star 2 (Fig. 1*a* and *b*). The latter feature is ~5–10 times narrower than the broad 4,471-Å/Hβ minimum around star 2, reflecting the reduced He I emissivity (proportional to He^+ density) in the He III region. We are confident, therefore, that the O star exhibits photospheric He I absorption with an estimated equivalent width (EW) of 0.2–0.4 Å.

From the CCD images we have also extracted the optical spectrum of star 2 by careful subtraction of the nebular contribution. Intensities and line ratios change so rapidly across N44C (and from pixel to pixel along the slit) that the elimination of nebular emission is far from perfect, causing spurious emission and/or absorption lines of nebular origin (Fig. 2). Nevertheless, the photospheric Balmer series in absorption confirms the presence of hydrogen in the atmosphere of star 2. Moreover, background subtracted spectra, aimed at an optimal cancellation of nebular Balmer lines, show that the Hγ absorption EW (2.2 Å) is typical of early O-type stars[9,10] and therefore imply normal hydrogen abundance. This result argues against star 2 representing an advanced hot stage of massive stellar evolution, because hydrogen would then be already strongly depleted on the surface[11–13] unless a very metal-poor composition and small mass-loss rate are assumed[14]. From spectral classification and temperature calibration of O stars[10,16], the observed He I 4,471-Å/He II 4,540-Å EW ratio (0.2–0.5) implies a spectral type O4 to O6 and an effective temperature in the range of 40,000–50,000 K. That star 2 is probably a moderately early main-sequence O star with little indication of mass loss is also supported by the lack of the N V 4,604–4,620-Å, N IV 4,058-Å and N III 4,634–4,641-Å features that are seen in early Of stars[16]. The absence of stellar He II 4,686-Å emission indicates that the star is not a giant or supergiant.

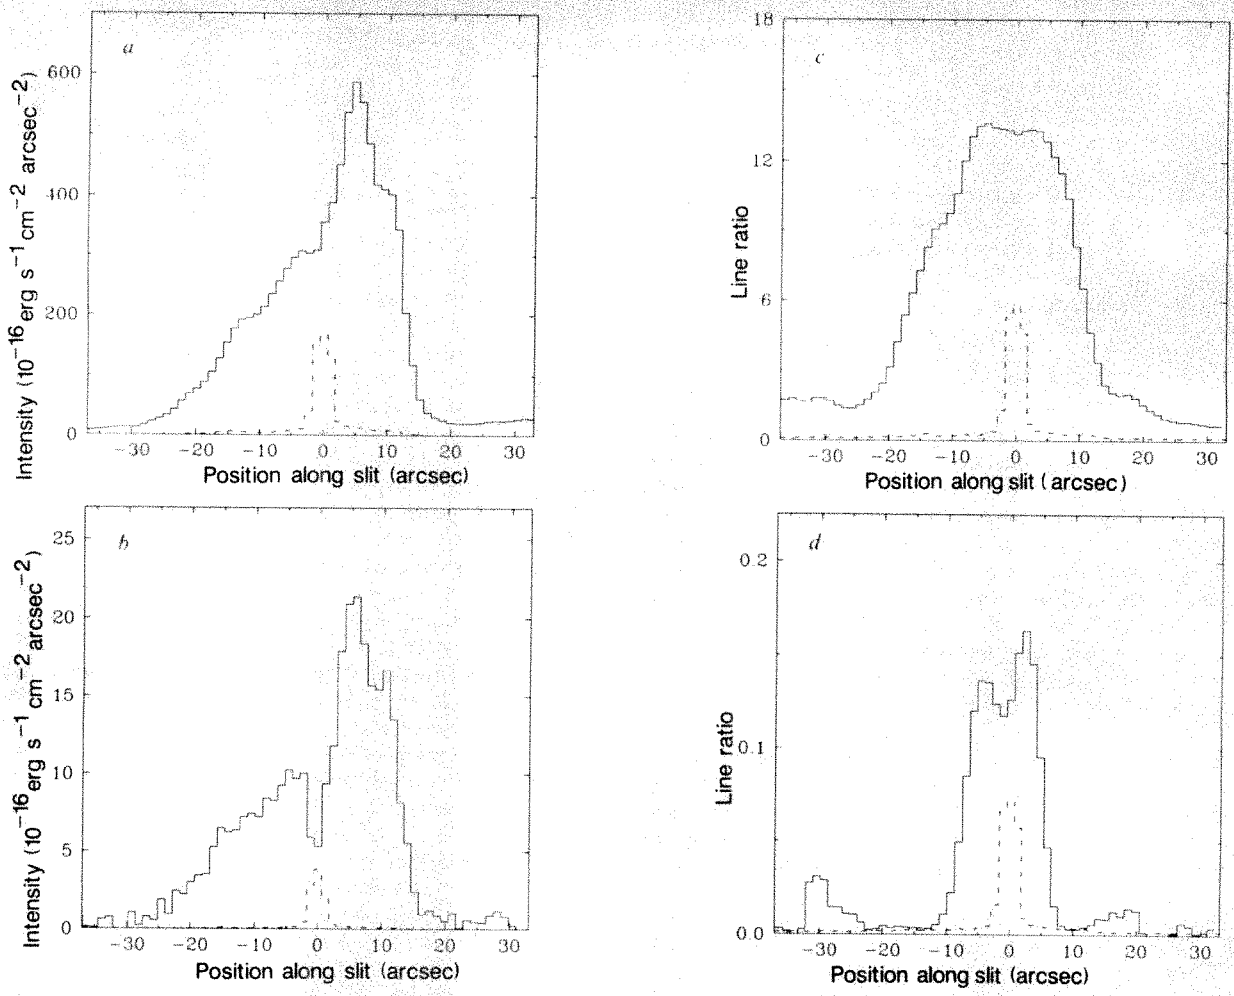

Fig. 1 Histograms of Hβ (*a*) and He I 4,471-Å (*b*) emission, and [O III] 4,959-5,007-Å/[O II] 3,727-Å (*c*) and He II 4,686-Å/Hβ (*d*) line ratios, in N44C as a function of position along the slit (position angle 313.°3; SE: left; NW: right). Stellar and nebular continuum flux at nearby wavelengths has been subtracted. The spatially unresolved dip in *b* indicates photospheric He I absorption in star 2; compare Fig. 2. The ionization structure in *c* and *d* is highly symmetric and is centred on star 2. The stellar continuum radiation scaled down by an arbitrary factor is shown for comparison in the dot-dashed curves. 1 arcsec corresponds to 0.25 pc in the LMC. The extent of the 4,686-Å emission (He III region) is 4.5 pc.

Recent calculations of nonlocal-thermodynamic-equilibrium-model atmospheres[17] of O stars indicate that the He^+ Lyman continuum can be strongly enhanced relative to plane-parallel models without stellar wind[7], when spherical extension and mass loss are taken into account. We have computed the expected 4,686-Å recombination flux, $F_{4,686}$, from such a model for the O4f star ζ Pup, to which star 2 is comparable except for its much weaker stellar wind. Using the well-known Zanstra method to link $F_{4,686}$ to the stellar brightness in the visual, we find that this model underestimates the 4,686-Å flux, measured as 1×

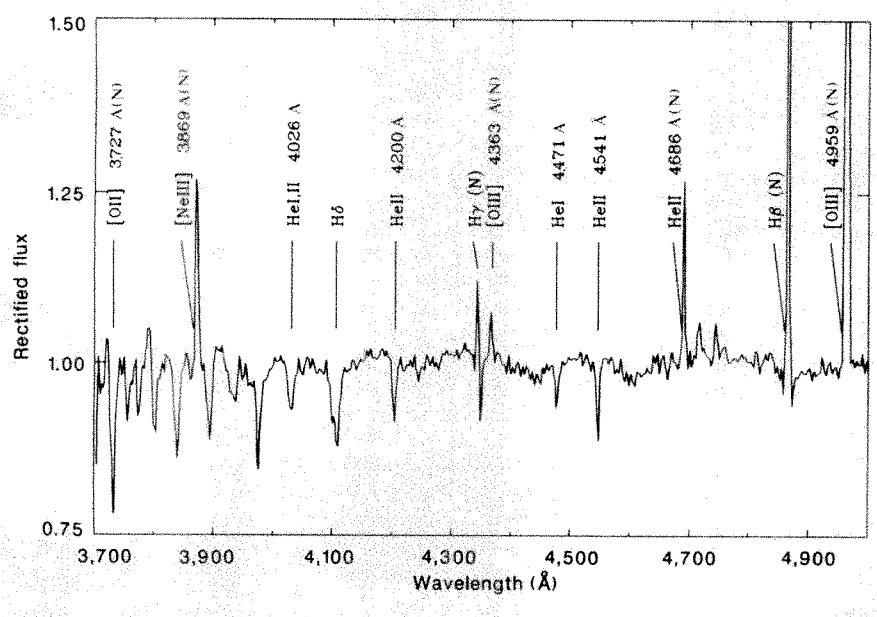

Fig. 2 Rectified optical spectrum of star 2. Spurious emission and absorption features (marked N) are due to imperfect subtraction of the nebular background. Note the presence of photospheric H I, He I and He II absorption lines, indicative of an O4–O6 V spectral type.

10^{-12} erg cm^{-2} s^{-1} (note that the value reported in ref. 3 is in error (G. Stasinska, personal communication)), by a factor of 130. Our observations therefore do not support the suggestion that star 2 is an extremely hot star capable of producing the N44C ionization structure.

An alternative interpretation[3], in terms of ionization by a strong stellar wind or supernova blast wave colliding with the interstellar medium, is also inconsistent with the observations. In this mechanism, high shock velocities in excess of 100 km s^{-1}, and accordingly high electron temperatures ($T_e(O^{2+})$ > 24,000 K), in the O III region are required to produce substantial fractions of He^{2+} ions[18], whereas the observed temperature[3] (12,000 K) clearly indicates that N44C is photo-ionized. We also note that the radial velocity of the 4,686-Å emission, 302 ±5 km s^{-1}, corresponds within 5 km s^{-1} to those of lower ionized species in the N44 complex, which effectively rules out a chance projection of a galactic planetary nebula onto the face of the LMC.

Guided by the strong resemblance of the optical emission-line spectrum to that of the He III region N159F surrounding the luminous X-ray binary LMC X-1 (ref. 4), we explored the conjecture that N44C represents an X-ray photo-ionized nebula (XIN). However, in the 0.15–4.5-keV Einstein satellite survey of the LMC (ref. 19), no X-ray emission from the vicinity of N44C was detected, and re-analysis of a previously unpublished Image Proportional Counter (IPC) observation of N44 (8,000 s integration time on 2 July 1980; F. Seward, personal communication) places an upper limit of 2×10^{35} erg s^{-1} on non-resolved X-ray emission from star 2. This value is 2,000 times smaller than the XIN hypothesis would predict (see below), excluding the possibility that the X-ray source was sufficiently active at that time. On the other hand, there is independent support for earlier X-ray activity in 1974–1976 from OSO-7 and Ariel V observations[5,6], which reveal a soft (2-keV) variable source, LMC X-5, at a celestial position consistent with that of N44C, although the relatively large errors preclude an unequivocal identification[19,20].

Adopting the fossil XIN interpretation of N44C, we can estimate the former luminosity of the currently inactive X-ray source. Drawing on photon-counting arguments[4] for the XIN around LMC X-1 and assuming the same soft X-ray and extreme ultraviolet spectral distribution for both sources, the observed flux $F_{4,686}$ corresponds to a recombination line luminosity, $L_{4,686}$ of 3×10^{35} erg s^{-1}, and therefore implies a 2–10-keV X-ray luminosity, L_x of $\sim(2\text{–}4)\times10^{38}$ erg s^{-1}. As some $He^{2+}\rightarrow He^{+}$ recombination must have occurred since X-ray activity ceased, this value represents a lower limit, implying that the source must have ranked amongst the most luminous X-ray binaries known.

A further important indicator of high nebular ionization is [Ne V] 3,426-Å emission, which line is produced at an ionization potential of 97.1 eV. This line is present in the XIN N159F (ref. 4) with a maximum intensity relative to Hβ, $I_{3,426}/I_\beta$, of 0.3, but is not detected in N44C with an upper limit of 0.05. How can this observation be reconciled with the fossil XIN hypothesis? To answer this question we note that recombination of Ne^{4+} is determined mainly by electron capture; charge-transfer reactions with H^0 are negligible because the ultraviolet radiation of star 2 maintains strong hydrogen ionization in the nebula. The recombination timescale is therefore $\tau_{Ne^{4+}} = (\alpha(Ne^{4+}, T)\, n_e)^{-1}$ where $\alpha(Ne^{4+}, T)$ ($=9\times10^{-12}$ cm^3 s^{-1} for $T = 10{,}000$ K (refs 21, 22)) is the Ne^{4+} recombination coefficient and n_e is the electron density. Therefore, [Ne V] 3,426-Å emission decays on a timescale of 16 $(n_e/200\ \text{cm}^{-3})^{-1}$ years after the extinction of the X-ray source (an electron density of 200 cm^{-3} has been assumed to be representative for N44C (ref. 3)). As recombination of He^{2+} takes place on a longer timescale ($\tau_{He^{2+}} = [\alpha(Ne^{4+}, T)/\alpha(He^{2+}, T)]\ \tau_{Ne^{4+}} = 6.5\ \tau_{Ne^{4+}}$), the combination of strong 4,686-Å and the absence of 3,426-Å radiation in N44C allows us to directly estimate the time, t_{off}, that has elapsed since the switch-off the X-ray source. Taking into account light travel-time effects, we find $20\ \text{yr} < t_{off}(n_e/200\ \text{cm}^{-3}) < 100$ yr. $\tau_{He^{2+}}$ also represents the timescale for the formation of the He III region[23], and therefore provides a lower limit, t_{on}, for the duration of strong X-ray activity in the past ($t_{on} > 10^2\ (n_e/200\ \text{cm}^{-3})^{-1}$ yr).

The concept of fossil nebulae being in an ionization state that is inconsistent with the presently observed ultraviolet sources they contain has been discussed previously in the context of planetary nebulae[24], H II regions, active galaxies (ref. 25 and references therein) and the interstellar medium around young supernova remnants[26,27]. However, the evolutionary timescales associated with significant decreases of the ionizing flux are in most cases much longer than the recombination and cooling timescales in the nebulae. The estimated lifetime of highly luminous massive X-ray binaries ($\sim10^4$–10^5 yr (ref. 28)) seems also to be too large to render fossil XINs observable. On the other hand, several 'permanent' sources (as opposed to the short-lived transients) are known to switch off for extended (>several years) time intervals[29,30], demonstrating that in these systems, X-ray active phases can alternate with periods of quiescence on timescales much shorter than those determined by stellar evolution. (Although this phenomenon has not been observed previously in close X-ray binaries with O-star primaries.) This as yet poorly understood behaviour implies the existence of a non-negligible number of fossil XINs which are observable if the density of the interstellar medium is sufficiently high.

A key test of the XIN hypothesis for N44C is the prediction that orbital motion of the advocated close compact binary companion causes star 2 to exhibit periodic radial-velocity and possibly ellipsoidal light variations. From our observations we derive an upper limit of 60 km s^{-1} to any such velocity variations. This value is of the same order as the radial-velocity amplitudes displayed by the O-star companions of several luminous X-ray pulsars[31] to which the proposed, presently inactive X-ray binary in N44C might be compared.

We thank Grazina Stasinska, Mohammed Heydari-Malayeri and Gerard Testor for discussions, Fred Seward for providing the Einstein IPC observation of N44C, Klaus Reinsch for CCD photometry of star 2, and the ESO staff for building and maintaining the long-slit spectroscopic facility.

Orbital evolution of circumplanetary dust by resonant charge variations

Joseph A. Burns* & Les Schaffer†

Department of Theoretical and Applied Mechanics, Cornell University, Ithaca, New York 14853, USA

Vast ethereal rings composed of micrometre-sized particles have been detected about the three giant planets so far visited by Voyager. Jupiter's diffuse halo, main ring[1] and gossamer ring[2] are visible because of the dust they contain. Small particles are also important constituents of Saturn's tenuous outlying rings: the contorted slender F ring[3], the G ring[4–6] and the extensive E ring[6,7]. At Uranus, dust was discerned by imaging[8] amidst, as well as inwards of, the nine previously known narrow rings; plasma measurements[9,10] suggest that micrometre grains are also present in an orbit of 4.4 times the planet's radius, where Voyager 2 pierced the planet's equatorial plane. Here we identify an orbital evolution mechanism for gravitationally dominated dust that may temporarily overwhelm other processes, and we derive evolution rates that agree with numerical integrations; we also indicate briefly how this process could affect the location of the faint rings evident today.

The orbits of micrometre-sized grains in planetary rings are governed mainly by gravity, but electromagnetic forces provide significant perturbations[11,12]. Such effects accumulate at discrete locations in the rings, Lorentz resonances[13], where specific components of the perturbations match orbital periods and cause orbital eccentricity e and inclination i to be large. These positions may determine the boundaries of Jupiter's ring[1,11,13]. But Lorentz resonances and electromagnetic processes in general have not previously been thought to change secularly the orbital size (semi-major axis a), although gyro-phase drift[14] and diffusive transport[15] may be effective for the tiniest grains (radius $s \lesssim 0.1\ \mu m$)[6, 12, 16, 17]. The orbital evolution of dust has been ascribed instead to plasma (Coulomb) drag, with the Poynting-Robertson effect being a lesser contributor[15,16,18].

Grains become electrically charged because any surface in space develops a potential through photo-ionization by solar radiation and through the currents carried by the local plasma to their surfaces. About the giant planets, photo-ionization can be ignored if the magnetospheric plasma is dense (number density $\eta \geq 10^2\ cm^{-3}$) and/or energetic. Thus, assuming perfect absorption of an isotropic and maxwellian plasma and no secondary emission, and ignoring the discrete nature of the charging process, the history of a particle's instantaneous charge Q is followed by summing the flows of positive and negative ions to the grain[19,20]:

$$\frac{dQ}{dt} = \pi s^2 \eta q w \left[\left(1 + \frac{\alpha^2}{2w^2} + \frac{2q|\Phi|}{m_i w^2} \right) \mathrm{erf}\left(\frac{w}{\alpha} \right) + \frac{\alpha}{w\sqrt{\pi}} e^{-(w/\alpha)^2} \right] - 2\sqrt{\frac{2\pi kT}{m_e}} s^2 \eta q e^{q\Phi/kT} \quad (1)$$

where q and m_e are the electron charge and mass, w is the speed of the grain relative to the mean plasma (assumed co-rotating with the planet), T is the plasma temperature, $\alpha = \sqrt{2kT/m_i}$ is the thermal speed of the ions, and k is the Boltzmann constant. The grain's potential $\Phi = Q/s$ reaches equilibrium when $dQ/dt = 0$. The equilibrium potential $\bar{\Phi}(T, w) = \bar{Q}/s$ is shown in Fig. 1 for plasma conditions that might apply to a jovian ring grain. The dependence of Φ on w principally reflects changes in the ion flux to the grain, because the electron flux is essentially independent of w when $\sqrt{2kT/m_e} \gg w$. A stationary grain develops a negative charge to ward off the swift electrons. For $w/\alpha \lesssim 2$, the ion current is reduced (because Coulomb attraction is less effective at focusing ions) so that $\bar{\Phi}$ decreases further, and eventually, at large w/α, the ion current is due primarily to ram charging onto the grain, so that $\bar{\Phi}$ increases linearly with w/α.

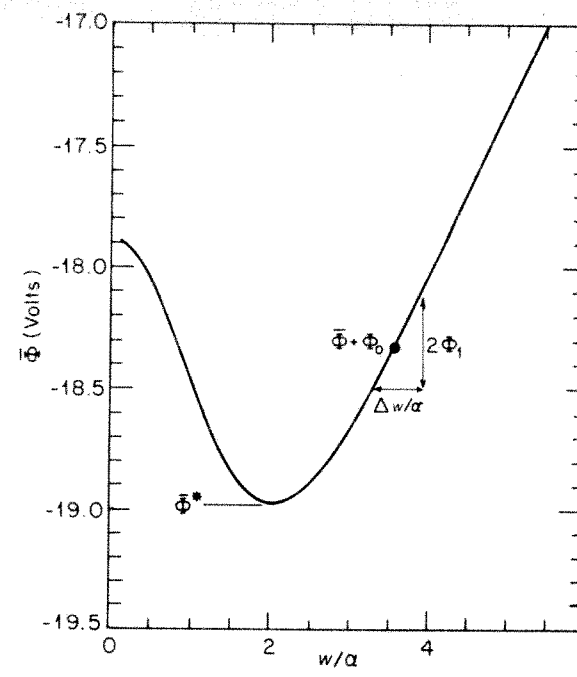

Fig. 1 A grain's equilibrium potential as a function of the ratio of w, the grain's speed through the plasma, to the ion thermal speed α for a plasma of O^+ at a temperature of 5 eV. Φ^* is the minimum potential that can be attained. Φ_1 is roughly the variation in the potential that occurs as w/α changes with high η.

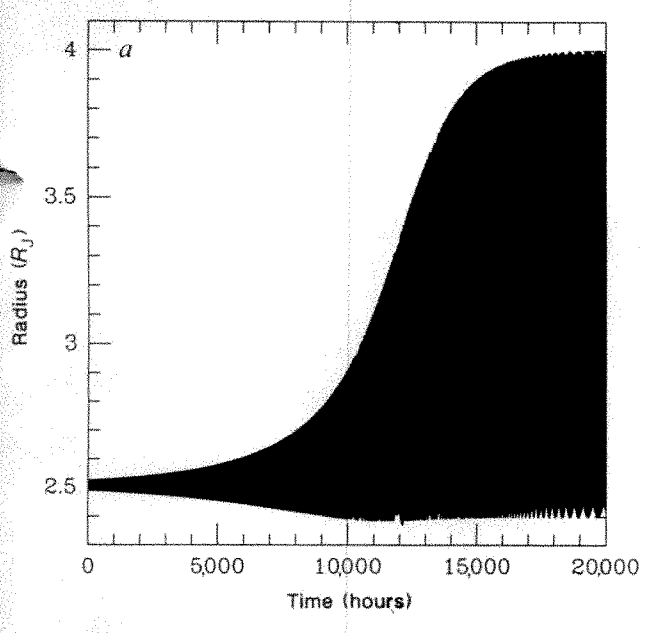
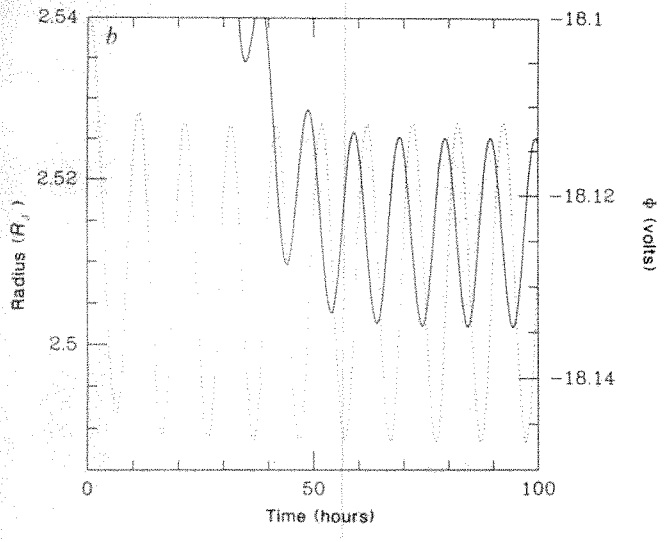
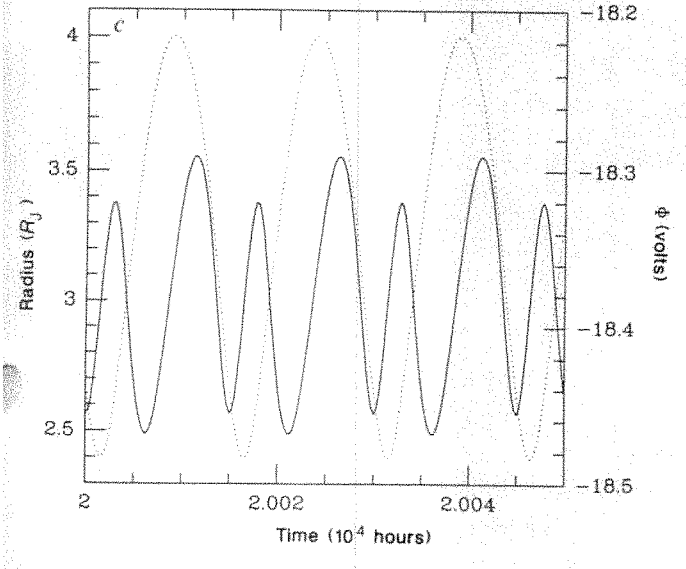
Q will vary systematically during the grain's orbit because the state of the plasma (η, T and even composition) varies with position and because a grain's velocity relative to the ambient co-rotating plasma varies along an elliptic orbit. Expanding equation (1) about $\bar{Q}$ (ref. 21) gives an inhomogeneous linear first-order differential equation for $\Delta Q = Q - \bar{Q}$ showing that small harmonic changes in w, η or T cause harmonic variations in ΔQ, which are phase-delayed because it takes some time to acquire the charge appropriate to local conditions. Allowing for large orbital excursions, the grain's charge can be expressed in general (compare refs 17 and 21) as



$$Q = \bar{Q} + Q_0 + Q_1 \cos(\theta - \theta_1) + Q_2 \cos 2(\theta - \theta_2) + \ldots \quad (2)$$



where time has been replaced by θ, the orbit's true anomaly or its angular position from pericentre, and where (Q_i, θ_i) are the strengths and phase lags of the various Fourier terms, which will be functions of the mean orbital position.



Present evidence indicates that particle sizes and potentials in tenuous planetary rings are such that motions are gravitationally dominated[6,11]. Here we concentrate on the orbital evolution caused by the charge variations produced, in turn, by velocity changes along an elliptical orbit. The case of electromagnetically dominated grains, where particles gyrate about and drift across magnetic field lines, has been analysed previously[14] and applied to a jovian grain's evolution[17].

Figure 1 indicates the charge variation along an orbit if the charging time is much less than an orbital period; $\bar{Q} + Q_0$ is then the mean charge for a particular orbit and Q_1 is roughly the maximum excursion about this value; Q_2 and higher-order

* Also at the Department of Astronomy, Cornell University, Ithaca, New York 14853, USA.
† Also at the Astronomy Unit, Queen Mary College, London E1 4NS, UK.

terms are present only when large changes occur in w/a (so that linearization in velocity variation is inappropriate) or when the orbit is such that the minimum potential $\bar{\Phi}^*$ (Fig. 1) is achieved. The Q_1 term indicates that a part of the charge varies with the orbital period; hence a delayed resonant perturbation acts on the particle, causing orbital evolution by a process that we call resonant charge variation.

We consider grains moving through the equatorial plane of an axially symmetric magnetic field:

$$\mathbf{B} = B_0(R/r)^3[1+\beta(R/r)^3+\ldots]\hat{\boldsymbol{\phi}}$$

where B_0 is the dipolar magnetic field at the planet's surface ($r = R$), $\beta(\ll 1)$ is the relative octopole strength and $\hat{\boldsymbol{\phi}}$ is the unit normal to the equatorial plane in the direction of the planet's spin $\boldsymbol{\Omega}$. Near the planet, the plasma is carried by the magnetic field, producing, in the inertial reference frame, a 'co-rotational' electric field $\boldsymbol{\mathcal{E}} = \Omega R b\hat{\mathbf{r}}/c$, where c is the speed of light and $\hat{\mathbf{r}}$ is the radial unit vector.

The orbital evolution of semi-major axis a and orbital eccentricity e is determined solely by the rates of change of the orbit's specific mechanical energy, $E = -GM/2a$, and angular momentum, $\mathbf{H} = \sqrt{GMa(1-e^2)}\hat{\boldsymbol{\phi}}$ (ref. 22); G is Newton's gravitational constant and M is the planet's mass. Thus, $a^{-1}\,\mathrm{d}a/\mathrm{d}t = \dot{E}/E$ and $\mathrm{d}e^2/\mathrm{d}t = (e^2-1)(2\dot{H}/H + \dot{E}/E)$. To integrate $\dot{a}/a$ over an orbit in the inertial frame, only the work done against $\boldsymbol{\mathcal{E}}$ needs to be considered because magnetic forces do no work ($\mathbf{v}\cdot(\mathbf{v}\times\mathbf{B}) \equiv 0$). Thus the semi-major axis changes at the average rate

$$\frac{1}{a}\frac{\Delta a}{\Delta t} = \frac{2a}{mGMP_0}\oint Q\boldsymbol{\mathcal{E}}\cdot\mathrm{d}\mathbf{r} \qquad (3)$$

where m is the grain's mass and the path integral is taken over a complete orbital period P_0. Using the magnetic-field expression above, we find

$$\frac{1}{a}\frac{\Delta a}{\Delta t} = \frac{B_0\Omega(R/a)^3 e}{nmc(1-e^2)}\left\{Q_1\sin\theta_1 + \frac{\beta(R/a)^2}{(1-e^2)^2}\times [Q_1(1+e^2/4)\sin\theta_1 + Q_2\sin 2\theta_2] + \ldots\right\} \qquad (4)$$

where $n = 2\pi/P_0 = (GM/a^3)^{1/2}$ is the orbital mean motion.

Similarly,

$$\Delta\mathbf{H} = \frac{B_0R^3}{mcH}\oint Q\dot{r}\,\mathrm{d}\theta\hat{\boldsymbol{\phi}} \qquad (5)$$

The co-rotational electric field does not enter because, being radial, it produces no torque. From this, the rate of change of e can be calculated; it is written most compactly as

$$\frac{\Delta e^2}{\Delta a/a} = (1-e^2) - (1-e^2)^{1/2}\left(\frac{n}{\Omega}\right) \qquad (6)$$

which can also be derived from the problem's Jacobi integral[21].

We can compare results from these analytical expressions with numerical simulations of a charged grain's evolution. We use a Runge–Kutta scheme[11,21] that, given a grain's position and velocity, computes accelerations resulting from Lorentz

◀ **Fig. 2** *a*, The orbital history of a 1-μm grain of density 1 g cm^{-3} placed in a 5-eV O^+ plasma ($\eta = 1$ cm^{-3}). The grain was launched on an initially circular equatorial orbit at 2.54 R_J, R_J being the radius of Jupiter. The parameters are chosen to produce rapid evolution. *b*, The grain's orbital radius r (dotted) and its electric potential Φ (solid) are shown with finer time resolution during the early evolutionary portion of Fig. 2*a*. The orbital period is roughly 10 hours. The phase lag θ_1 is evident. *c*, The same quantities as in *b* but plotted at a later time, when the charge variation is primarily doubly periodic and the orbit has stabilized. Because of the greater distance to Jupiter and the larger Lorentz force, the period has lengthened to almost 15 hours.

forces plus non-point-mass gravity and, through Newton's equations, the consequent orbital evolution; simultaneously, the grain's charge state is followed by using equation (1). Figure 2 shows the numerically determined orbital history of a jovian dust grain, using the appropriate values for Jupiter, $B_0 = -4.092$ G and $\beta = 0.028$ (compare ref. 11). The orbit quickly becomes eccentric because the initial path is not in centripetal equilibrium once the change develops, which occurs rapidly. As deduced from Fig. 1 and equation (2), charge varies at first primarily with the orbital period, like w, and exhibits a phase lag θ_1.

After ~9,000 hours, the grain evolves rapidly outward while its eccentricity grows. This drift can be understood from equations (3) or (4): because of the phase lag, the grain's mean charge is slightly more negative during its inbound motion than on its outbound path (see Fig. 3). The electric field thus does positive work during each radial oscillation and the orbit size expands. When e has reached a value of ~0.2, the evolution slows dramatically, for two reasons. First, as Fig. 2c suggests and a Fourier transform attests, Q then varies primarily in the second harmonic, which, for the same charge variation, is 10^{-2}–10^{-3} times as effective as Q_1, according to equation (4). Q_2 has developed because, with such a large e, w/α ranges from about 0.2 to nearly 4 (see Fig. 1); in addition, θ becomes a multi-periodic function of time, inducing Q_2. Second, despite the large excursion in w/α, charge variations (especially Q_1) are fairly small because the changes in w/α occur too swiftly for equation (1) to respond. The numerically computed rates, based on measured Q_i and θ_i, compare very favourably with our analytical expressions. We note that the very low η, chosen here to cause a large θ and a rapid evolution, is incompatible with our neglect of photo-ionization; under these circumstances, resonant pulsations in Q caused by passage through the shadow are important perturbations (M. Horanyi, personal communication).

In many of our numerical experiments the orbit size changes faster than would be expected from either plasma drag[6,15,16] or Poynting-Robertson (P-R) drag[23]. For example, during the steep-sloped mid-portion of Fig. 2a, $\dot{a}$ is about 250 cm s^{-1}, whereas the plasma drag and P-R evolution rates are two to three orders of magnitude less[6,17]; in denser plasmas, Coulomb drag could, however, dominate orbital evolution because its strength would increase at the larger density whereas the evolution caused by resonant charge variation would decrease. Nevertheless, the orbit's stabilization, which is apparent in Fig. 2a and which, as we have argued, is implicit in the charging scheme when velocity variations drive equation (1), means that dust will not inevitably leave the system.

The orbital evolution (equations (4) and (6)) will depend upon the nature of the charge variation ($Q_1, Q_2, \ldots, \theta_1, \theta_2, \ldots$), which in turn will be fixed by the orbit, because the latter imposes the time history for w, T and η in the charging relation (equation (1)). Other orbits or different plasma environments can produce

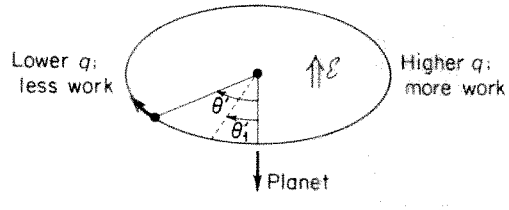


Fig. 3 The motion of a charged, orbiting grain as seen in a reference frame rotating at the mean orbital rate. The particle moves clockwise along this curve from pericentre (nearest the planet) to apocentre and back to pericentre. Because of the phase lag θ'_1, the mean charge on the right-hand side of the path is more negative than on the left-hand side so that more work is done moving toward the planet than away from it. A similar argument shows that the second harmonic is much less efficient in moving grains (compare equation (4)). For small eccentricity the plotted angle θ' approximately equals the true anomaly θ.

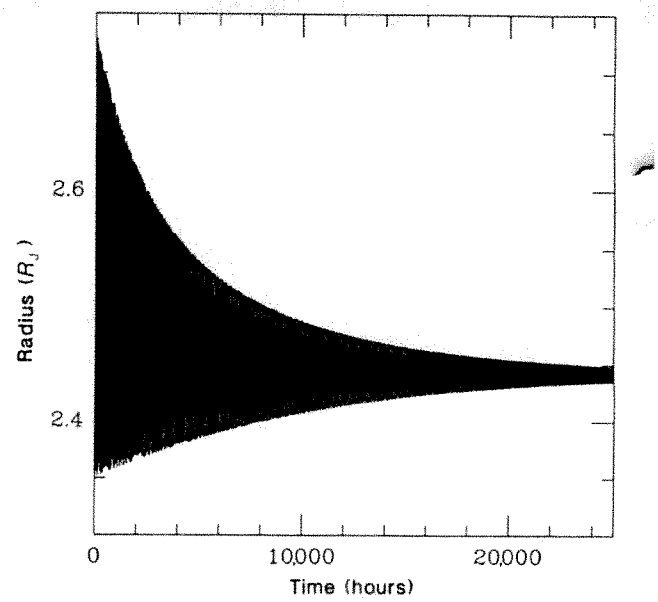

Fig. 4 The orbital history of a 0.34-μm grain of density 1 g cm^{-3} placed in a 0.2-eV O^+ plasma with density $\eta = 10$ cm^{-3}. The particle is introduced with some initial radial velocity to provide enough eccentricity to initiate noticeable evolution.

dramatically distinct histories. Figure 4 shows a grain placed in the same position as for Fig. 2 but in a plasma such that the particle's potential is to the right of $\bar{\Phi}^*$ on Fig. 1, and changes more quickly. A smaller grain size is chosen to make the perturbation forces comparable in the two examples. The grain's evolution is opposite, and the particle moves slowly toward the synchronous position while the orbit circularizes.

What might orbital evolution by resonant charge variation imply for the genesis of the faint rings? Because dust from a single source can be disseminated widely to populate a region both inside and outside the source (compare Fig. 2), it is possible for Enceladus to supply the whole E ring of Saturn, which straddles the satellite's orbit and extends out as far as Rhea's orbit. Similarly, the faint material surrounding Saturn's F ring[6,24] may be the evolved debris from collisions occurring in the ring itself. Given appropriate plasma conditions in the jovian magnetosphere, grains from distributed parents in the gossamer ring could move toward synchronous orbit to produce the enhancement observed there (Fig. 4; compare refs 2 and 17); this would require either that w/α be more than several (which is difficult to achieve near synchronous orbit) or that T increase toward synchronous orbit. For Uranus, the dust detected at $4.4R_U$ may have drifted inward from the outlying classical satellites rather than, as previously maintained[10], necessarily being derived from the small moon 1985U1, the only known object between synchronous orbit and the point of detection.

Resonant charge variations can produce rapid orbital evolution of dust, but the precise rate, and even the direction, of evolution depends sensitively on plasma parameters and dust sizes in inner planetary magnetospheres. Because these quantities are not as yet well determined, it is very difficult to predict the transport of dust within faint planetary rings.

We appreciate T. G. Northrop's prodding questions which led us to this research. We acknowledge comments and computational help from R. A. Kolvoord and M. Horanyi. We thank K. Mospan and B. Boettcher for technical assistance. This research was supported by NASA.

The winter solstice phenomenon at Newgrange, Ireland: accident or design?

T. P. Ray

School of Cosmic Physics, Dublin Institute for Advanced Studies, Dublin 2, Ireland

On Midwinter's Day, around four and a half minutes after sunrise, the sun shines down the 'roof-box' of the Neolithic passage graves at Newgrange, Ireland, and illuminates the floor of its main chamber 18 m away. When the monument was constructed, however, first light would have occurred at sunrise in the form of a very narrow beam bisecting the chamber. Here I suggest that the width and height of the gap in the floor of the roof-box may have been deliberate, tracing the path of the Sun at the solstice. Newgrange predates the astronomical structures of Stonehenge by 1,000 years and as such may be the oldest astronomically orientated structure in the world.

Located some 50 km from Dublin, Newgrange is the largest in a group of Neolithic passage graves in the Boyne Valley, County Meath. Although discovered in 1699, the tomb was not properly excavated until the 1960s[1]. It consists of a passage and chamber off which are three smaller alcoves (Fig. 1), giving the structure an overall cruciform appearance. Surrounding it is a large circular mound, over 80 m in diameter, of loose stones, and encircling this again is an incomplete ring of standing stones. The mound and ring are, however, not concentric and probably not contemporaneous.

As early as 1909, Lockyer[2] remarked that the passage grave was approximately aligned to the rising Sun at midwinter. He did not, however, pay much attention to the site. During recent excavations of Newgrange, O'Kelly[1] unearthed a curious decorated structure located above the entrance to the tomb. This structure, which was later to be called the 'roof-box'[1], covered a vertical gap between the first and second roof slabs of the passage. Conscious of a local tradition that the chamber was illuminated by the Sun at a certain time of year, O'Kelly[1] investigated whether the roof-box had some solar function, and found that the midwinter Sun shone through the roof-box and gap to illuminate the central chamber of the tomb (Fig. 2) 18 m away. This event would have occurred even if access to the tomb was blocked by the entrance stone[1].

Patrick[3] later concluded that the orientation of the roof-box towards the winter solstice was deliberate. Heggie[4] has pointed out, however, that on the basis of Patrick's calculations, the Sun would illuminate the main chamber if its declination lay at any position between −22°58′ and −25°53′, and hence the probability of a solsticial alignment in the corresponding range of azimuths is about 1 in 13. Heggie[4] concluded that this fact was 'not really significant enough to excite much interest'. But Heggie's calculation is in error for two reasons. First, as will be discussed below, Patrick's upper azimuth limit is about 1° too high and hence the declination range should be reduced accordingly. Second, and more importantly, the three-dimensional aspect of this problem has been ignored. As can be seen from Fig. 2, the solsticial light from the roof-box meets the floor at a glancing angle within the main chamber. If the gap between the first two roof-slabs was, say, 20 cm lower, or equivalently the passage was a few metres longer, sunlight would not enter the chamber. In fact, one would then observe the Boyne Valley, rather than the local horizon, through the gap. Correspondingly, if the gap was higher, the solsticial light would have been projected onto the back wall. Although such an alignment is of course admissible for statistical purposes, it would not have as dramatic an effect as that of a glancing beam on the floor. Thus the chance of Newgrange being accidentally aligned with a solsticial sunrise/sunset point is smaller, at least by a factor of two, than the figure quoted by Heggie[4]. Nevertheless the evidence still remains weak and it would not rival that found for sites such as Stonehenge[4] and Kintraw[5]. To test the solar hypothesis further, we re-surveyed the roof-box, as seen from the main chamber, and the local horizon in the direction of sunrise on Midwinter's Day.

The passage itself is sinuous (Fig. 1), restricting the range of azimuths from which a ray of light can enter the main chamber. We found this range to be 133°49′-137°29′ at the chamber

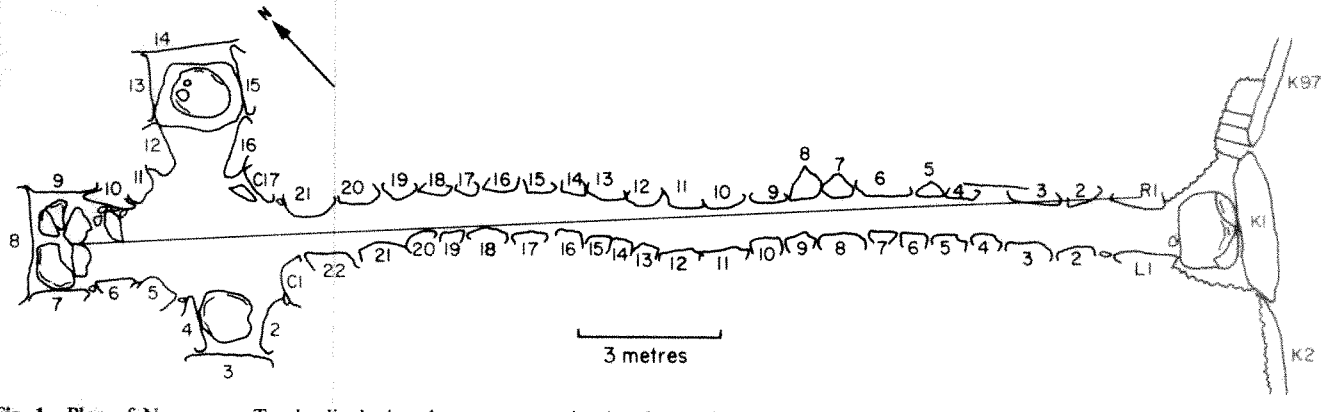

Fig. 1 Plan of Newgrange Tomb, displaying the passage, main chamber and its three alcoves. The marked line shows the minimum azimuth or 'first-light' axis of the passage. This axis coincides with the direction of Midwinter sunrise 5,150 years ago, when the tomb was built. Adapted with permission of C. O'Kelly.

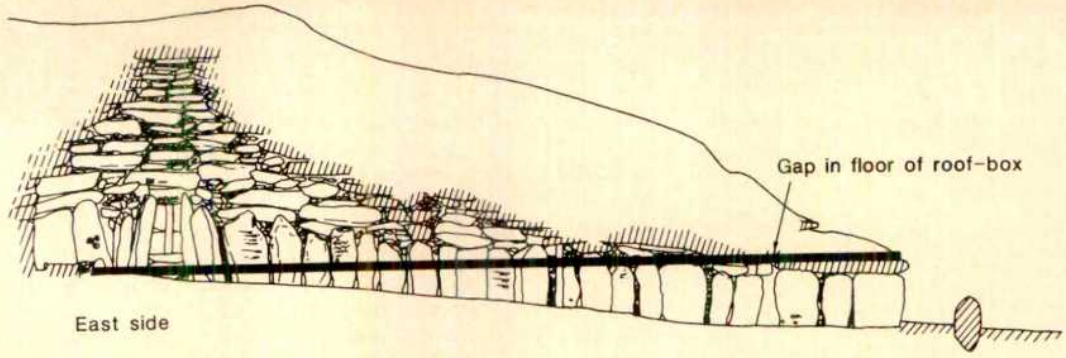

Fig. 2 Sectional elevation of the east side of Newgrange. The path of the first rays of the Sun around 3,150 BC is indicated.

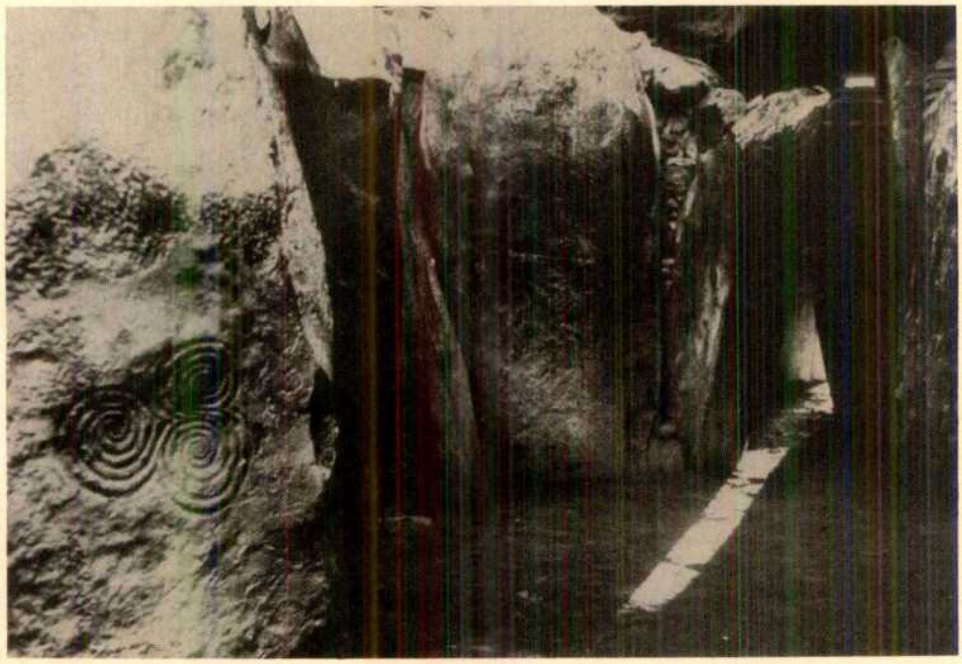

Fig. 3 Sunlight in the main chamber at the time of the winter solstice. The three-leafed spiral figure can be seen in the backmost alcove. Photo courtesy of Conn Brogan, Office of Public Works, Dublin.

entrance, with a typical error of about ±3′. The upper limit is ~1° greater than that quoted by Patrick[3]. We measured the light beam to be just under 34 cm wide near the entrance although it narrows towards the back recess, largely because stone L20 leans inwards. Close to the entrance to the chamber, however, L20 restricts the width of the light beam by 8 cm at most, so that if L20 were uprighted the minimum azimuth would be less than the quoted value by only 20′. The chamber floor is slightly lower than the gap in the roof-box (Fig. 2) and hence at low altitudes, the light of the Sun is spread across the floor. The minimum altitude at which sunlight can enter the chamber is given by the height of the local horizon, 55′ ± 2′, whereas the maximum altitude, confirmed by actual timing measurements of when the Sun disappeared (F. Prendergast, private communication) from the main chamber, is 2°11′ ± 2′. Using height measurements of the gap behind the roof-box and the chamber floor, we found that light at minimum elevation would reach at least 1 m into the back recess (Fig. 1). However, sunlight is now seen to extend only as far as the edge of this alcove, because the minimum azimuth axis, or 'first light' axis, of the passage does not point towards midwinter sunrise. In fact, light from the right-hand limb of the Sun first enters the main chamber four and a half minutes after sunrise (F. Prendergast, personal communication), and at that time the Sun is almost completely above the horizon.

The question then arises as to what would have been the solar alignment when the monument was built. Carbon dating of two charcoal samples from between the roof-slabs yielded radiocarbon ages of 4,450 ± 40 and 4,460 ± 45 BP[1]. To convert this to a calendar date, we have used the dendrochronological record provided by samples of Irish Oak[6]. This indicates that the probable construction period for the site is 3,150 ± 100 BC. For these dates the obliquity of the ecliptic would have been[7] 24°2′ ± 1′ and the midwinter Sun would rise at an azimuth of 133°54′ ± 4′. Here we have assumed, for calculating refraction[8], a pressure of 1,010 mbar, a temperature of 0 °C and the height of the local horizon to be 55′ ± 2′. Variations in temperature and pressure make very little difference to the result. We see that the Sun would have risen just within the limits of the roof-box as seen from the main chamber. In other words, the 'first-light' axis of the passage corresponds, within 5′ or so, to midwinter sunrise 5,150 years ago. If, at that time, one assumes that stone L20 was in an upright position, the accuracy would still be better than 25′. It follows that when Newgrange was built, the first beam of sunlight on the floor was less than 10 cm wide, approximately 2 m long, and bisected the chamber (Fig. 1). Rather curiously, this beam would have entered the back recess and indirectly illuminated a three-leafed spiral figure on its wall (see Fig. 3), as mentioned in legend[3,4,9].

As the Sun's altitude and azimuth increased, the beam would have become gradually broader. The height of the gap behind the roof-box varies between 18 and 22 cm, being 20 cm on average. As seen from the main chamber 18 m away, this gap subtends an angle of roughly 38′, so that the risen Sun is framed

in the vertical direction. Finally, the lower edge of the Sun would have left the roof-box, as seen from the main chamber, at an azimuth of 137°42′ ± 5′. Again this is very close to the maximum azimuth of the passage, implying a symmetry with respect to the Sun's passage at the winter solstice. Thus not only the height but also the width of the gap may be significant.

Newgrange predates the astronomically orientated structures (phase III) of Stonehenge by about 1,000 years. The evidence presented here supports the theory that the orientation of Newgrange was deliberate, which would make it therefore the oldest megalithic structure known for certain to have an astronomical function[4,5]. The alignment at Newgrange was within a fraction (that is, within $\frac{1}{2}°$) of the Sun's disk although it is doubtful whether the accuracy extends to the level of a few arcminutes. Newgrange should be seen in the light of large-scale studies such as those of Ruggles[10], which show definitive evidence that megalithic man was interested in marking the southern limits in declination of the Sun and Moon, albeit approximately. Such low accuracies suggest that ancient man's interest in these bodies may have been ritualistic rather than for the purpose of calendar construction.

A superconducting copper oxide compound with electrons as the charge carriers

Y. Tokura*, H. Takagi† & S. Uchida†

* Department of Physics and † Engineering Research Institute, University of Tokyo, Bunkyo-ku, Tokyo 113, Japan

Since the discovery of high-temperature superconductivity in copper oxide compounds[1], there has been much effort to understand what is required for a compound to have a high transition temperature (T_c). Up to now, all of the families of high-T_c copper oxide superconductors have contained two-dimensional sheets of Cu–O pyramids or octahedra, and the carriers of the superconducting current have been electron vacancies, or 'holes'. By contrast, we report here the discovery of a family of superconducting copper oxides in which the carriers are electrons. The new superconductors are Ce^{4+}-doped compounds, with the formula $Ln_{2-x}Ce_xCuO_{4-y}$, where Ln stands for the lanthanides Pr, Nd or Sm. The compounds have the Nd_2CuO_4 (T′-phase) structure[2], which is composed of sheets of Cu–O squares (see Fig. 1*a*). This structure has no apical oxygen atoms, in contrast to the T-phase structure with Cu–O octahedra (Fig. 1*b*), as observed in $La_{2-x}Sr_xCuO_4$ (refs 1, 2), and the T*-phase structure with Cu–O pyramids (Fig. 1*c*), as in $Nd_{2-x-z}Ce_xSr_zCuO_4$ (ref. 3 and Y. T. *et al.*, manuscript in preparation).

The superconducting materials were synthesized from a mixture of rare-earth metal oxides (CeO_2, Pr_6O_{11}, Nd_2O_3, Sm_2O_3) and CuO. The mixed powder was calcined in air at 950 °C for 10 hours, pressed into pellets and sintered in air at 1,150 °C for 12 hours. The samples were quenched in air to room temperature, and were found to be single-phase. To produce superconductivity, the Ce-doped samples were annealed for 10 hours under reducing conditions—at 1,000 °C in a stream of an Ar/O_2 gas mixture with $p_{O_2} < 10^{-3}$ atm—and quenched to room temperature in the same atmosphere. Best results were obtained with $p_{O_2} \approx 8 \times 10^{-5}$ atm.

Figure 1 shows the temperature dependence of resistivity for $Nd_{2-x}Ce_xCuO_{4-y}$. Although the undoped compound Nd_2CuO_4 is a typical semiconductor, doping with Ce^{4+} ions increases the conductivity (Y. T. *et al.*, manuscript in preparation). A remarkable decrease in resistivity was also observed in the undoped sample on quenching from 1,150 °C in air down to room temperature, which produces an oxygen deficiency ($y \approx 0.04$). These observations indicate that Ce^{4+}-doping and/or oxygen deficiencies introduce mobile electrons into the parent compound. The T′-phase Nd-based copper oxide cannot be doped with holes (Y. T. *et al.*, manuscript in preparation), whereas the T*-phase compound $Nd_{2-x-z}Ce_xSr_zCuO_4$ (Fig. 1*c*) can be doped with holes but not with electrons, which is also the case for the T-phase structure (Fig. 1*b*).

A fairly low resistivity ($\lesssim 10^{-2}\ \Omega$ cm) was observed for $Nd_{2-x}Ce_xCuO_{4-y}$ for $x = 0.15$, the sample showing semimetallic but not superconducting behaviour. (In Fig. 2, however, this sample shows a resistivity drop at around 9 K, which indi-

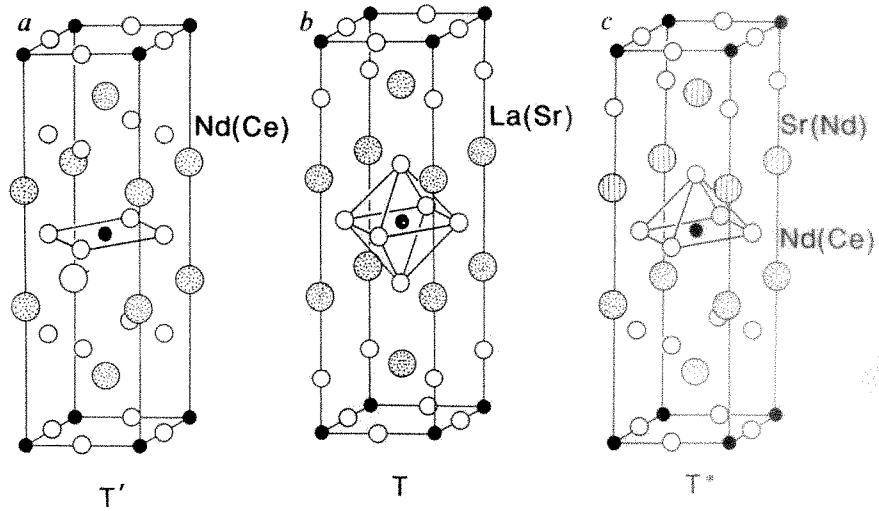

Fig. 1 Crystal structures of *a*, $Nd_{2-x}Ce_xCuO_4$ (T′-phase), *b*, $La_{2-x}Sr_xCuO_4$ (T-phase) and *c*, $Nd_{2-x-z}Ce_xSr_zCuO_4$ (T*-phase).

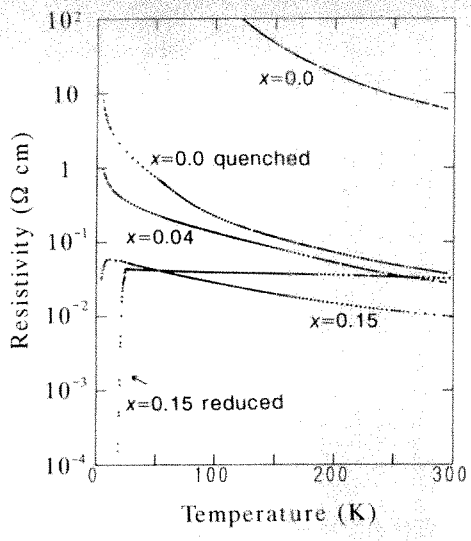

Fig. 2 Resistivity of $Nd_{2-x}Ce_xCuO_{4-y}$ as a function of temperature. In the $x = 0.15$ sample, after reduction, there is an onset of superconductivity at $T_c \approx 24$ K.

cates superconductivity in a small portion of the sample.) Bulk superconductivity in the $x = 0.15$ sample was achieved by the annealing procedure described above. Both resistivity and magnetization measurements indicated an onset of superconductivity at ~24 K. The concentration (q) of electrons introduced per [Cu-O] unit, or the effective copper valence ($2 - q$), was estimated by an iodometric titration technique[4] in which Ce^{4+} is reduced to Ce^{3+}. The $x = 0.15$ sample used to obtain Fig. 2 has $q = 0.20$ before the reducing procedure, and $q = 0.28$ after this procedure (that is, when it is superconducting). This corresponds to an increase in oxygen vacancies ($y \approx 0.07$). Therefore, an increase in electron density beyond a certain value ($q \approx 0.20$) seems to initiate superconductivity in which electrons are the charge carriers.

That the carriers are electrons was also confirmed by measurements of the Hall coefficient. The sample $Nd_{1.85}Ce_{0.15}CuO_{3.93}$, with $T_c = 24$ K, shows a negative Hall coefficient: $R_H = -6.5 \times 10^{-4}$ cm^3 C^{-1} at 300 K and -2.3×10^{-3} cm^3 C^{-1} at 80 K. This observation contrasts sharply with the other copper oxide superconductors so far known, in which positive Hall coefficients are always observed, indicating hole-type carriers.

The X-ray diffraction pattern for $Nd_{1.85}Ce_{0.15}CuO_{3.93}$ is shown in Fig. 3*a*, and, for comparison, those of the hole-superconducting T-phase $La_{1.85}Sr_{0.15}CuO_4$ (Fig. 3*b*) and T*-phase $Nd_{1.4}Ce_{0.2}Sr_{0.4}CuO_4$ (Fig. 3*c*) (see also Fig. 1). The diffraction pattern of $Nd_{1.85}Ce_{0.15}CuO_{3.93}$ is essentially identical to that of the undoped T′-phase compound Nd_2CuO_4, and all diffraction peaks discernible in Fig. 3*a* can be indexed assuming the lattice constants of the typical tetragonal T′-phase structure[2], $a = 3.95$ Å and $c = 12.07$ Å. The CuO_4 square in the T′-phase is considerably expanded and the c axis shrunk, relative to the T- and T*-phase structures, for which $a = 3.78$ Å, $c = 13.2$ Å, and $a = 3.85$ Å, $c = 12.5$ Å, respectively.

Electron-superconductivity is not restricted to the Nd-based compounds, but is also evident in the T′-phase of Pr- and Sm-based copper oxide compounds Ce-doped and reduced by the same procedure; again the electron concentration must be increased beyond $q = 0.20$, and superconductivity occurs at around 20 K. In Fig. 4 we show measurements of the Meissner effect in three different samples, $Ln_{1.85}Ce_{0.15}CuO_{4-y}$ (with Ln representing Pr, Nd and Sm), carried out using a SQUID magnetometer in an applied field of 10 Oe under field-cooled conditions. A substantial Meissner signal was observed in all of the compounds. In particular, the large signal for $Nd_{1.85}Ce_{0.15}CuO_{3.93}$—more than 25% of the ideal value—

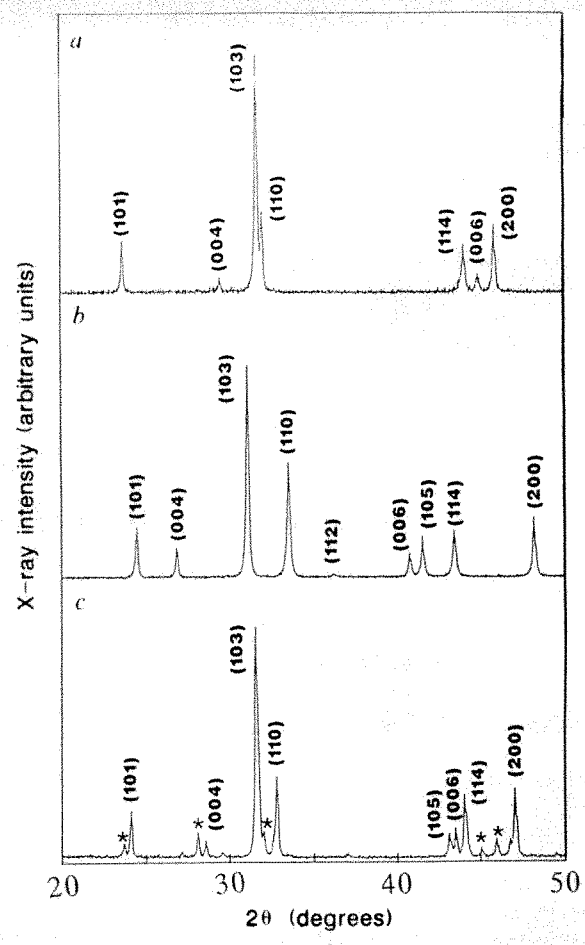

Fig. 3 Powder X-ray diffraction patterns of *a*, $Nd_{1.85}Ce_{0.15}CuO_{4-y}$, (T′-phase), *b*, $La_{1.85}Sr_{0.15}CuO_4$ (T-phase) and *c*, $Nd_{1.4}Ce_{0.2}Sr_{0.4}CuO_{4-y}$ (T*-phase). Asterisks indicate peaks from a secondary phase.

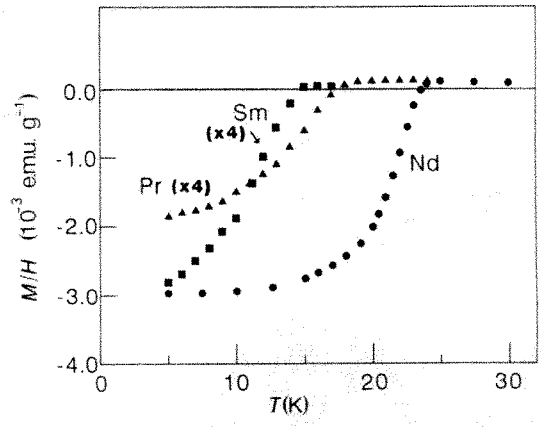

Fig. 4 Meissner signals in T′-phase $Ln_{2-x}Ce_xCuO_{4-y}$ (where Ln represents Pr, Nd or Sm). We plot the ratio of magnetization M to applied field H, for $H = 10$ Oe.

confirms the bulk nature of superconductivity. The observed T_c (24 K) is comparable with those in the corresponding hole-superconducting single-layer copper oxides: $T_c = 28$ K in the T*-phase (with Cu-O pyramids) and $T_c = 40$ K in the T-phase (with Cu-O octahedra).

The compound $Pr_{1.85}Ce_{0.15}CuO_{4-y}$ (Fig. 4) is the first example of a Pr-based copper oxide superconductor. Hole-doped Pr-based copper oxides, such as the T*-phase compound $Pr_{2-x-y}Ce_xSr_zCuO_{4-y}$ (Y. T. *et al.*, manuscript in preparation) and the 1-2-3 compound $PrBa_2Cu_3O_7$ (ref. 5), show neither metallic nor superconducting behaviour. This has been

attributed to the partial trapping of doped holes by Pr ions, or equivalently to the mixed-valent nature of Pr^{n+} ions ($3 < n < 4$). The appearance of superconductivity in $Pr_{2-x}Ce_xCuO_{4-y}$ further implies that the carriers are electrons in this T'-phase compound, because Pr^{3+} cannot be further reduced.

In conclusion, we have demonstrated for the first time that electron-doping in copper oxide compounds having the T'-phase structure, comprising CuO_2 sheets with no apical oxygen, gives rise to superconductivity. This observation may contain important implications for theories of high-T_c superconductivity.

We thank H. Matsubara and H. Watabe for their assistance in experiments. This work was supported by a grant-in-aid for special distinguished research from the Ministry of Education, Science and Culture of Japan.

Recently, a new copper oxide superconductor with an onset temperature of 28 K was found in the Nd–Ce–Sr–Cu–O system[1]. The superconducting phase was identified by X-ray diffraction and electron microscopy[2], and the metal-atom positions are identical with those in the K_2NiF_4 or Nd_2CuO_4 structure[3], except for the order of the cations Nd(Ce) and Sr. Here we report the refinement of the crystal structure using neutron powder diffraction. We find that it comprises alternating slabs of the K_2NiF_4 and Nd_2CuO_4 structures, and that all the copper atoms are crystallographically identical, with oxygen in fivefold (square-pyramidal) coordination. In having only one kind of copper site, this new compound is structurally simpler than the other CuO_5-bearing superconductors such as $YBa_2Cu_3O_7$, and may therefore be particularly helpful in the effort to understand the origins of high-temperature superconductivity.

A sample with the composition $(Nd_{0.66}Sr_{0.205}Ce_{0.135})_2CuO_{4-\delta}$ was prepared by mixing Nd_2O_3, $SrCO_3$, CeO_2 and CuO in the appropriate ratio. The mixture was pressed into a pellet, reacted in air at 1,150 °C for 15 h, and then cooled to 900 °C. The reacted mixture was pulverized, pressed into a pellet and reheated under the same conditions. Finally, it was annealed at 550 °C for 12 h under a high pressure of O_2 (80 kg cm^{-2}), which, as has been observed before (ref. 2 and Y. Tokura *et al.*, preprint), increases both the superconducting volume fraction and T_c.

Our sample showed an onset of superconductivity, from magnetization measurements, at 22 K. The Meissner signal reached ~12% of the ideal value ($-1/4\pi$) at 8 K.

Initial structural parameters for use in a Rietveld analysis of the neutron data[4] were obtained by preliminary refinement of X-ray powder diffraction data. The X-ray data were measured at room temperature using a Rigaku diffractometer with rotating-anode source and graphite monochromator. Intensity data were collected with Cu Kα radiation at 0.02° intervals. The diffraction pattern indicated that the sample was nearly free from impurities. Rather low R factors were obtained: $R_{wp} = 12.9\%$, $R_p = 9.8\%$, $R_I = 8.6\%$, $R_F = 5.9\%$ and $R_e = 7.8\%$. The X-ray data were sufficient to determine the arrangement of the metal ions; a structure refinement on neutron powder diffraction data was carried out to obtain reliable structure parameters for oxygen.

Table 1 Structure parameters of $(Nd_{0.66}Sr_{0.205}Ce_{0.135})_2CuO_{4-\delta}$

Atom	Site	x	y	z	g	$10^3\beta_{11}$	$10^3\beta_{22}$	$10^3\beta_{33}$	B (Å^2)
M	2c	0	$\frac{1}{2}$	0.3895 (3)	1	—	—	—	0.47 (7)
M′	2c	0	$\frac{1}{2}$	0.1038 (3)	1	—	—	—	0.64 (7)
Cu	2c	$\frac{1}{2}$	0	0.2510 (3)	1	7 (1)	7 (1)	10 (2)	0.48
O(1)	4f	0	0	0.2374 (3)	1	11 (2)	17 (2)	24 (3)	1.05
O(2)	2c	$\frac{1}{2}$	0	0.4288 (5)	0.93 (2)	83 (5)	83 (5)	12 (4)	3.55
O(3)	2a	0	0	0	1	6 (2)	6 (2)	24 (4)	0.76

Estimated standard deviations in parentheses refer to the last digit. The temperature factor is defined as $\exp(-h^2\beta_{11} - k^2\beta_{22} - l^2\beta_{33})$. The occupation factors, g, of Nd, Ce and Sr are fixed at 0.49, 0.1 and 0.41 for site M, and at 0.83, 0.17 and 0.0 for site M′. Isotropic thermal parameters, B, were refined for sites M and M′; equivalent isotropic thermal parameters, B_{eq}, are given for sites Cu, O(1), O(2) and O(3).

Table 2 Interatomic distances, r, in $(Nd_{0.66}Sr_{0.205}Ce_{0.135})_2CuO_{4-\delta}$

Bonds	r (Å)	N*
M–O(1)	2.706 (2)	4
M–O(2)	2.7707 (6)	4
M–O(2†)	2.268 (4)	1
M′–O(1)	2.550 (2)	4
M′–O(3)	2.3231 (9)	4
Cu–O(1)	1.9355 (2)	4
Cu–O(2)	2.221 (3)	1

* Number of equivalent bonds.
† Coordinate triplet: y, $1-x$, $1-z$.

The neutron diffraction data were obtained on a high resolution time-of-flight neutron powder diffractometer, HRP, at the KENS pulsed spallation neutron source at the National Laboratory for High Energy Physics. The specimen was contained in a cylindrical vanadium cell. The scattering angle, 2θ, was fixed at 170°, and intensity data were collected at room temperature for 20 h, using a gate width of 4 μs. Intensity data corresponding to interplanar spacings, d, between 0.51 and 3.37 Å (7,012 points) were used for Rietveld refinements. Preferred orientation was corrected on the assumption that the cleavage plane is (001), using a gaussian preferred-orientation function.

The observed data are consistent with just one of the three models proposed by Takayama-Muromachi *et al.*[2]. Final structure parameters are listed in Table 1, and selected metal–oxygen distances in Table 2. The refined lattice parameters are $a = 3.8563\ (3)$ Å and $c = 12.4842\ (9)$ Å. R factors were $R_{wp} = 5.9\%$, $R_p = 4.5\%$, $R_I = 3.5\%$, $R_F = 2.7\%$ and $R_e = 4.8\%$. Figure 1 shows the final profile fit and difference patterns. The good agreement between observed and calculated patterns strongly supports the proposed structural model.

Because the occupation factor, g, and thermal parameters for site O(2) are considerably correlated, these parameters cannot be determined very accurately. However, taking $g = 1$ for site O(2) gave larger R factors and a larger thermal parameter ($B_{eq} = 4.26$), suggesting that this site is slightly oxygen-deficient. The oxygen stoichiometry $4-\delta$, calculated from the measured g, is 3.93. The increase in superconducting volume fraction and in T_c that accompanies oxygen annealing presumably results from an increase in occupation of this site.

The equivalent thermal parameter of site O(2) was fairly large: $B_{eq} = 3.55$ Å^2. The anisotropic thermal parameters U_{11} and U_{33}

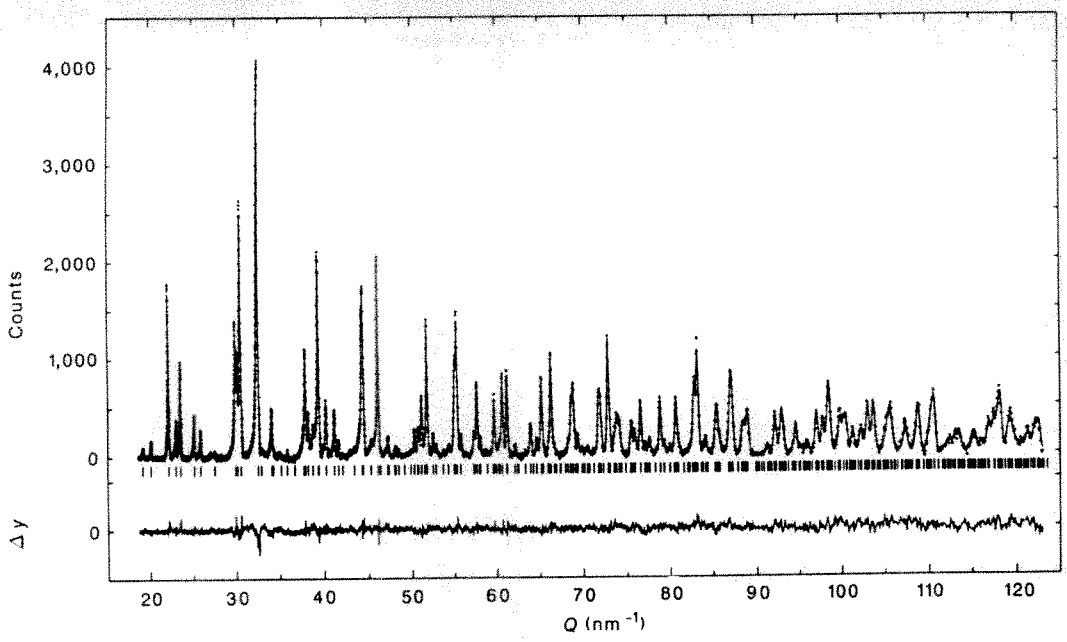

Fig. 1 Rietveld refinement of a time-of-flight neutron diffraction pattern for $(Nd_{0.66}Sr_{0.205}Ce_{0.135})_2CuO_{4-\delta}$. Scattering vector $Q = 2\pi/d$, where d is the interlayer spacing. The solid lines are calculated intensities, crosses indicate experimental data, and Δy is the difference between the two. The short vertical lines mark the positions of 501 peaks.

are, respectively, 0.063 Å^2 and 0.0092 Å^2, indicating that the thermal ellipsoid of O(2) expands perpendicular to the c axis. This marked anisotropy of thermal vibration is understandable in view of the relatively short Cu-O(2) and M-O(2) bonds parallel to the [001] direction. In addition, the large value of U_{11} for this site must be partly due to the random distribution of Nd, Ce and Sr atoms at site M.

The coordination numbers of M, M′ and Cu are, respectively, 9, 8 and 5. Sr^{2+} ions, which are larger than Nd^{3+} or Ce^{3+} (or Ce^{4+}) ions, selectively occupy the 9-coordinate site at $(0, \frac{1}{2}, \sim 0.39)$. The average M-O distance (2.69 Å) is much larger than that of M′-O (2.44 Å). The CuO_5 pyramid contains four short Cu-O(1) bonds (1.9355 Å) and one long Cu-O(2) bond (2.221 Å), but the Cu-O(2) bond is shorter than those in other superconductors with such CuO_5 pyramids, such as $YBa_2Cu_3O_7$ and $Tl_2CaBa_2Cu_2O_8$. The valence of Cu, calculated using the Brown-Altermatt formula[5], is 2.23. The bases of the pyramids form a two-dimensional CuO_2 plane perpendicular to the [001] direction. The M-O(2) bond parallel to the [001] direction is only 2.268 Å, which is comparable with the Cu-O(2) distance.

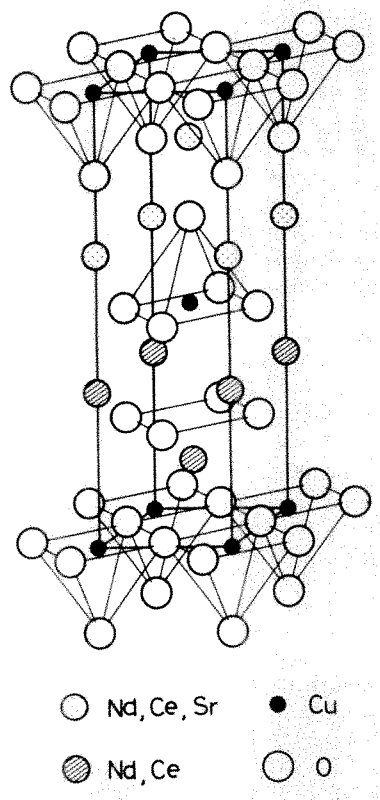

Fig. 2 Crystal structure of $(Nd_{1-x}Sr_{x-y}Ce_y)_2CuO_{4-\delta}$.

The crystal structure of $(Nd_{1-x}Sr_{x-y}Ce_y)_2CuO_{4-\delta}$ is shown in Fig. 2. The unit cell consists of two parts: the upper part in Fig. 2 corresponds to the K_2NiF_4 structure, in which the M (Nd, Ce, Sr) ion is coordinated to nine oxygen atoms, and the lower part exhibits the Nd_2CuO_4 structure, incorporating M′(Nd, Ce) ions in eightfold coordination. All of the copper atoms are in a single crystallographic site, with square-pyramidal coordination. High-T_c superconductors are classified into two structural groups, those that contain copper in distorted octahedral coordination (for example, $(La_{1-x}M_x)_2CuO_4$ (where M is Ca, Sr or Ba) and $(Bi, Tl)_2(Sr, Ba)_2CuO_6$) and those that contain copper in pyramidal coordination (for example, $LnBa_2Cu_3O_7$ (where Ln is Y or various lanthanide elements), $(Bi, Tl)_mCa_n(Sr, Ba)_2Cu_{n+1}O_{m+2(n+2)}$ and $Pb_2Sr_2ACu_3O_{8+\delta}$ (where A represents Ln or Ln+(Sr or Ca))[6]). Clearly, $(Nd_{1-x}Sr_{x-y}Ce_y)_2CuO_{4-\delta}$ has the simplest structure of the 'pyramidal' superconductors.

Here we have assumed that Ce^{3+} ions occupy both the M and M′ sites. We are now examining the local and electronic structures of Ce by extended X-ray absorption fine structure (EXAFS) and X-ray photoelectron spectroscopy (XPS), with the aim of determining the distribution of Ce between these two sites. We are also investigating the apparent sensitivity of superconductivity to the Nd/Sr/Ce ratio.

We thank Professor Y. Tokura, Dr H. Takagi and Dr H. Fujiki for help and discussions. This work was supported by a Grant-in-Aid for Scientific Research on Priority Areas ('Mechanism of Superconductivity').

The phase diagram of boron nitride (BN) is similar to that of carbon, incorporating phases at high temperatures and pressures whose structures and physical properties resemble diamond[1–9]. Cubic zinc-blende-structured BN is especially important because it is extremely hard—second only to diamond. Here we report the first measurement of the 300-K equation of state of this material to ultrahigh pressures (115 GPa), and obtain a zero-pressure bulk modulus of 369 ± 14 GPa. A theoretical equation of state derived from first-principles pseudopotential calculations yields a 300-K isotherm that agrees with our experimental results to better than 2.5% in volume and 2.0% in bulk modulus. The high-pressure Hugoniot (shock-wave equation of state) calculated from our equation of state for BN is in good agreement with existing shock-wave data. Our study illustrates the reliability of current experimental techniques (such as the ruby-fluorescence calibration) and theoretical methods (pseudopotentials) for characterizing the behaviour of superhard, incompressible materials under high pressure.

At ambient conditions, BN exists in a hexagonal structure which is analogous to that of graphite. At pressures above 4.5 GPa and temperatures above 1,500 K, BN exhibits two polymorphs, corresponding to the diamond (cubic zinc-blende-structured) and lonsdalite (hexagonal wurtzite-structured) forms of carbon. Both the structure and the physical properties of zinc-blende-structured BN, the thermodynamically stable phase at high pressure, resemble those of diamond. Because of its extreme hardness, its chemical inertness, its high melting temperature (>3,000 K) and its high thermal conductivity (~200 $W m^{-1} K^{-1}$), cubic BN is commercially important[10]. But despite these unusual physical properties, there has been no direct experimental measurement of its equation of state. This lack of data is surprising because the value of the bulk modulus, for example, is of considerable importance in understanding the relationship between a crystal's structure, hardness and stability—information that can help in the design of new superhard materials with technological potential. In addition, the equation of state offers a powerful way of comparing the reliability and predictive power of current theoretical and experimental techniques for characterizing the physical properties of condensed matter. We have determined the equation of state of cubic BN to pressures in excess of 100 GPa by both experimental and theoretical means.

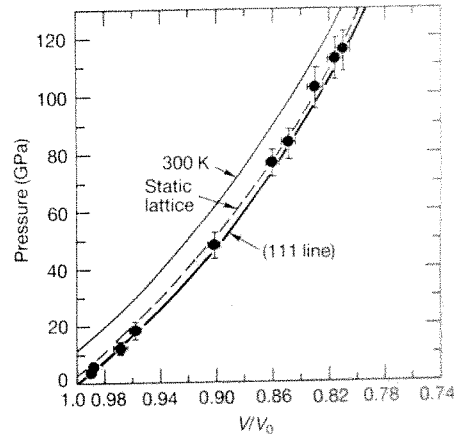

Fig. 1 Experimental pressure–volume data for cubic BN at 300 K (circles with error bars) are compared with theoretical isotherms for the static lattice (dashed curve) and for BN at 300 K (thin solid line). The thick solid line is the Birch–Murnaghan (third-order Eulerian finite strain) isotherm that is obtained from a least-squares fit to our static compression measurements. The reference volume used here is the volume measured at ambient conditions, V_0 = 7.113 $cm^3 mol^{-1}$, so the theoretical and experimental results are compared here in terms of absolute volume.

Table 1 High-pressure X-ray diffraction data for cubic BN

* a and b designate different samples.
† The lattice parameter is from the (111) diffraction line only. All other diffraction lines of cubic BN have intensities of less than 10% of the intensity of this line and therefore are not strong enough to be observed at high pressure.

The sample of cubic BN used in this study was supplied by R. C. DeVries of General Electric Corporation and comprised single crystals 30–50 μm in size. The lattice parameter, determined by X-ray diffraction at zero pressure, is 3.615 ± 0.002 Å. For the high-pressure experiments, gasketted samples of cubic BN were compressed in a Mao–Bell-type diamond cell between diamonds with 200-μm culets[11]. The sample region was typically 100 μm in diameter and 10 μm thick at high pressures. A 4:1 mixture of methanol:ethanol was used as a pseudohydrostatic pressure medium, and between two and five small pieces of powdered ruby were included with the BN sample for pressure measurement using the ruby-fluorescence technique[12,13]. A Mo K_α X-ray beam was collimated to a diameter of 80 μm and directed through the high-pressure samples along the axis of force of the diamond cell. X-ray diffraction patterns were recorded at pressures of between 0 and 115 GPa with typical run times of 100–150 hours.

The experimentally measured lattice parameters and volumes of cubic BN under pressure are listed in Table 1, and the isothermal equation of state is plotted in Fig. 1. To determine the zero-pressure values of the isothermal bulk modulus (K_0) and its pressure derivative (K_0'), we have analysed the data using a Birch–Murnaghan (third-order Eulerian finite-strain) equation of state[14]. Despite the large value of K_0 (369 ± 14 GPa), we have determined it and K_0' with considerable precision because of the high pressures that were reached[15].

The static structural properties of cubic BN were calculated using a first-principles total-energy approach[16] within a localized-orbital formalism[17]. The localized basis provides a more convenient representation than a plane-wave basis, which had been used in a previous calculation[18], because the valence states of BN are highly localized by the large depth of the angular-dependent components of the boron and nitrogen pseudopotentials. The formalism that we used is described in detail elsewhere[16,17], and as far as possible we chose the same approximations here as were used before[18–22]. To facilitate the evaluation

of matrix elements, the angular-dependent components up to $l=2$ were expanded in terms of gaussian functions using a Monte Carlo simulated-annealing method[23]. Up to 12 gaussians were used in the expansion of the sharp p-potentials, which resulted in fitting errors smaller than 0.01 Rydbergs. The wave-functions are expanded in a basis of Bloch sums of gaussian orbitals $f(r)$ centred on the atomic sites, which have the form:

$$f(r)=e^{-\alpha r^2}r^l Y_{l,m}(\Theta,\Phi)$$

Four and five even-tempered values of α are used for B and N respectively, and values of $l=0$ and 1 are included, so that there are 36 basis functions per molecule. The gaussian decays α for B and N were chosen by fully minimizing the total energy with respect to the smallest and largest αs in the even-tempered series. They are 0.23 and 5.80 for N, and 0.17 and 5.3 for B. Inclusion of states with d-symmetries shifted the energies for the equilibrium volume almost uniformly by ~0.1 eV per atom pair. This small change is typical of first-row elements, whose energy separation between the atomic d-states and the Fermi level is very large. The crystal potential is iterated to full self-consistency. To perform the summations in the Brillouin zone, the same ten k-point samplings as used in the earlier calculations were chosen[18].

The results of our calculations on cubic BN are shown in Fig. 2 and summarized in Table 2. The static-lattice energy was obtained at each of 12 volumes between 50 and 90 a.u.^{3} (1 atomic unit (a.u.) = 0.529 Å). To compare the results with 300-K data, we used the Debye model to derive the zero-point energy and the internal-energy difference between 0 K and 300 K. Our approach in making these vibrational corrections to the lattice energy is purely empirical: we use the experimental values of $\theta_D=1{,}800$ K for the Debye temperature and $\gamma_0=1.87$ for the Grüneisen parameter[10,24] referenced to the volume measured at ambient conditions, $V_0=79.78$ a.u.^{3}. Also, we assume that γ/V is constant (see, for example, ref. 25). Because of the large θ_D of BN the difference between lattice energies and static-lattice energies is almost entirely due to the zero-point energy, and the effect of compression is to increase the vibrational correction (through the effect on γ) so that the equilibrium volumes at 0 K and 300 K are larger than the volume for the static lattice.

The equilibrium properties derived from the calculations depend in detail on the form of the equation of state that is used to fit the energy–volume points. In Fig. 2 we have assumed that the energy is a third-order polynomial in the Eulerian finite-strain, as we did in our analysis of the experimental measurements[14], because this is identical to fitting pressure–volume data with the Birch–Murnaghan equation of state. Thus, we are treating our theoretical and experimental results identically, iteratively solving to obtain V_0 for the best-fitting equation of energy as a function of strain. We obtain values of 3.625 Å and 3.648 Å for the lattice parameters of the static and 300-K lattice, respectively, which agree with experiment to better than 1% (Table 2).

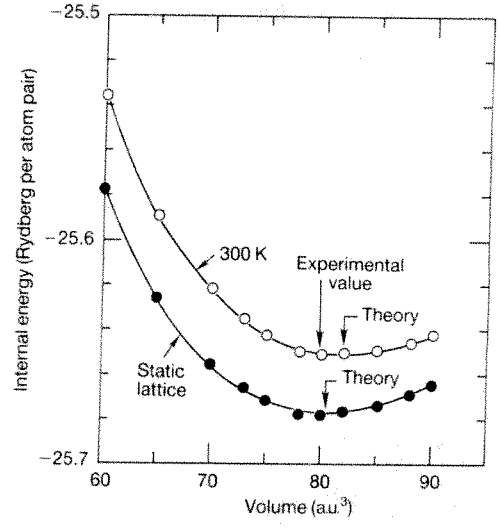

Fig. 2 Theoretical results for the internal energy (Rydberg per molecule) as a function of volume (in atomic units) of cubic BN. The static lattice energies (solid circles) are calculated using the LCAO pseudopotential approach. Corrections for zero-point energy and for the thermal energy between 0 K and 300 K were obtained from the Debye model, and the open circles represent the total energy at 300 K. The two curves show Eulerian finite-strain fits to the static-lattice and 300-K points, with the difference in energy between 0 K and 300 K being within the width of the 300 K curve. Arrows labelled Theory indicate the theoretical equilibrium volumes for the static lattice and at 300 K. These are derived from the fitted curves and are compared with the experimentally determined value for the volume at 300 K.

Our results compare favourably with the previous calculations using a plane-wave basis[18]. If a Murnaghan equation of state is used to fit the calculated points, as had been done in the earlier work, the differences between the equilibrium properties calculated for the static lattice for localized and plane-wave bases are small relative to the uncertainties (Table 2). These differences are comparable to the variation caused by changing the form of the equation of state used. In addition, absolute uncertainties are dependent on the convergence achieved and on the formulation used for the exchange and correlation energy (for example, the Hedin–Lundqvist expression[26]). Nevertheless, the high level of convergence achieved here is reflected in the cohesive energy (Table 2), which is slightly greater than was

Table 2 Comparison of the properties of cubic BN from experiment and theory

	Lattice parameter (Å)	K_0 (GPa)	K_0'	Cohesive energy E_{co} (eV per atom pair)	
Experiment (300 K)

† The experimental value for the cohesive energy of hexagonal BN is 13.0 eV (ref. 32). The cohesive energy for the zinc-blende phase should differ from this by ~0.1 eV (ref. 33). The somewhat larger value obtained theoretically is typical of calculations using the local-density approximation.

‡ Plane-wave basis as in ref. 18.

obtained in the plane-wave calculation. Apparently, using a finite number of plane waves in the latter calculations leads to a reduced estimate of the cohesive energy.

In Table 2 and Fig. 1, we compare the experimental and theoretical equations of state for cubic BN. The theoretical isotherms are obtained by adding the zero-point and thermal pressure derived from the Debye model to the negative volume-derivative of the static-lattice energy curve shown in Fig. 2. It is clear that although the calculated volume is slightly (but systematically) large, by 2.0–2.5% relative to the measured values, the theoretical equation of state is in excellent agreement with our experimental isotherm. In fact, the derived parameters K_0 and K_0' are identical, given the uncertainties and approximations involved (Table 2). We conclude, therefore, that the high-pressure compression of cubic boron nitride is well characterized by these theoretical and experimental results, confirming the predictions of our earlier study[18].

To check the reliability of our equation of state for cubic boron nitride, we compare our results with independent shock-wave (Hugoniot) measurements[5,27]. The advantage to the latter is that whereas static experiments depend on the ruby-fluorescence technique for calibrating pressures, the Hugoniot data represent direct measurements of volumes and pressures, free from any pressure calibration. However, the primary difficulties involved in interpreting shock-wave data are: (1) the need to apply thermal corrections and to account for initial sample porosity; (2) the possible influence of strength effects; and (3) possible kinetic hindrances in the case of shock-induced phase transitions.

The existing Hugoniot data for BN are obtained from polycrystalline samples that are initially in the low-pressure (hexagonal) polymorph, with variable porosity ranging between 5 and 10%. We calculate Hugoniots assuming that the hexagonal BN transforms entirely to the cubic phase (that is, that there is no kinetic hindrance) and that strength effects can be neglected. If either assumption is wrong, the actual Hugoniot states would be at pressures (or shock-wave velocities, U_s) greater than our calculated values for a given volume or particle velocity (u_p). The calculations are carried out using the Mie-Grüneisen and Eulerian finite-strain formalisms, with both initial porosity and the energy of transformation being taken into account[25,28].

Using the parameters listed under Fig. 3, we predict the high-pressure Hugoniot for BN in terms of U_s as a function of u_p. Although we cannot prove that cubic BN, rather than another phase or a mixture of phases, is formed at high shock pressures, the good agreement between the calculated and observed Hugoniots does support this inference. There is no evidence for strength effects or for partial transformation at $u_p > 2\ \mathrm{km\ s^{-1}}$, except in the pyrolitic samples of ref. 5. Even the curvature of the U_s–u_p trend is reproduced by our calculations (Fig 3). According to our model this curvature is due mainly to the initial sample porosity, although the experimental curvature may exceed that predicted above $u_p = 4.2\ \mathrm{km\ s^{-1}}$. We concur with Gust and Young[5] that the samples may be molten at these high shock pressures. For example, we estimate Hugoniot temperatures of 5,000–5,500 K at 100 GPa for the porous samples shown in Fig. 3; these values of temperature are probably low because they are obtained assuming that the specific heat is equal to the Dulong–Petit value[5]. Hence, shock-induced melting is a plausible explanation for the observed U_s being somewhat lower than our predicted values at Hugoniot pressures above 85 GPa ($u_p > 4.2\ \mathrm{km\ s^{-1}}$). As a result, we conclude that the shock-wave data are in good agreement with the equation of state that we have derived by static-compression measurements and by linear-combination-of-atomic-orbitals pseudopotential calculations. This provides implicit additional support for the validity of the ruby-fluorescence calibration used in static-compression experiments.

Previous empirical estimates of the bulk modulus of cubic BN range up to 465 ± 50 GPa. This value, based on the interpolation of empirical correlations for elastic constants, is clearly too high[29]. In contrast, a scaling argument in which the bulk modulus for diamond- and zinc-blende-structured compounds is inversely proportional to a power of the bond length leads to an estimate of 367 GPa for cubic BN (ref. 30). This is in close agreement with both our experimental and theoretical values of K_0, and it gives a prediction of K_0' that is close to our observed value of 4 (ref. 31). Furthermore, the scaling argument successfully reproduces the bulk moduli of a number of diamond- and zinc-blende-structured solids, including carbon (435 GPa), silicon (98 GPa) and germanium (76 GPa). The success of this scaling is consistent with the idea that shorter bond distances and smaller heteropolarities are associated with larger bulk moduli, and hence larger bond strengths and greater hardness, in tetrahedrally bonded solids.

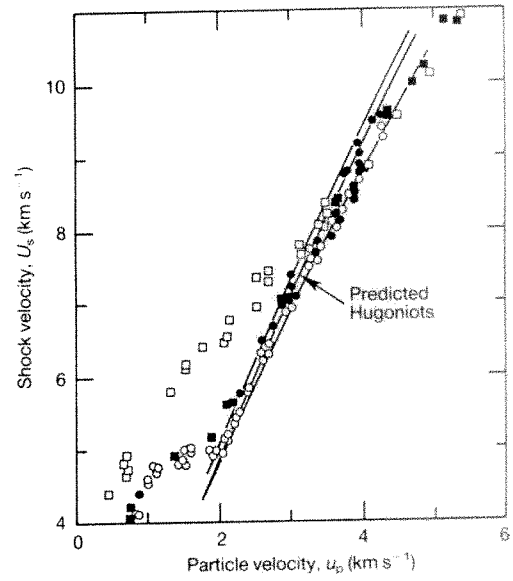

Fig. 3 Comparison of shock-wave data on BN with Hugoniots predicted from the present equation of state for cubic boron nitride. Open and closed squares represent the pyrolitic and hot-pressed samples of ref. 5, whereas the open and closed circles represent samples of ref. 28 with initial densities of 2.08 Mg m^{-3} and 2.11–2.15 Mg m^{-3}, respectively. The middle curve corresponds to the Hugoniot derived from the following parameters (notation as in ref. 28): $\rho_{00} = 2.10$ (±0.05) Mg m^{-3} (refs 5, 35), $\rho_{01} = 2.258$ (±0.001) Mg m^{-3} (ref. 35), $\rho_{02} = 3.489$ (±0.001) Mg m^{-3} (ref. 35), $K_{s02} = 371$ (±14) GPa, $dK_{s02}/dP = 4.0$ (±0.2), $\gamma_{02} = 1.87$ (±0.322) (refs 10, 24), $d\ln\gamma/d\ln V = 1$ and $E_{tr} = 5$ (±3) kJ mol^{-1} (ref. 10). The outer curves reflect the estimated uncertainties in the Hugoniot parameters.

We thank Dr R. C. DeVries for supplying us with the BN (borazon) starting material used in this study, and for helpful technical information and discussions. R.M.W. acknowledges the Conselho Nacional de Desenvolvimento Cientifico e Tecnologico (CNPq) of Brazil for financial support in the early stage of this work. This work was supported by the NSF and Department of Energy.

Evidence from Lewisian limestones for isotopically heavy carbon in two-thousand-million-year-old sea water

A. J. Baker*† & A. E. Fallick†

* Grant Institute of Geology, West Mains Road, Edinburgh EH9 3JW, UK
† Scottish Universities Reactor Research Centre, East Kilbride, Glasgow G75 0QU, UK

A number of 2,000-million-year-old marbles have extraordinarily heavy carbon isotope signatures ($\delta^{13}C \approx +12‰$ PDB)[1,2], suggesting that there was a worldwide excursion in the carbon isotope composition of sea water at this time. To test this hypothesis we have measured the carbon isotope signatures of 2,000-million-year-old amphibolite facies marbles from the Scottish Lewisian. The occurrence of a major isotope excursion is confirmed by the heavy carbon isotope signatures of these rocks ($\delta^{13}C$ up to +13‰ PDB), which we attribute to an origin contemporaneous with sedimentation. This excursion coincides with a major change in the redox state of the oceans which is likely to have induced considerable changes in the carbon cycle. We suggest that the excursion was due to increased rates of organic carbon deposition resulting from an increase in organic productivity.

Supracrustal rocks from the Loch Maree Group of the Lewisian were deposited after the main 2.7-Gyr granulite facies metamorphic event. These rocks include marbles, graphite schists, iron formations and quartzofeldspathic gneisses which underwent amphibolite facies metamorphism at 1.8 Gyr. The depositional age is unlikely to exceed 2.1 Gyr on the basis of the low initial $^{87}Sr/^{86}Sr$ ratio at the age of metamorphism[3], and of Sm–Nd crustal-residence ages[4]. The marbles include coarsely crystalline and microbrecciated varieties. Both quartz-present assemblages and quartz-absent, dolomite-bearing (such as tremolite–dolomite–calcite[5]) assemblages occur. Carbon and oxygen isotope compositions of calcites extracted from these marbles are shown in Fig. 1 and Table 1. A range of $\delta^{13}C$ and $\delta^{18}O$ values is found which may be attributed to interaction of marbles, initially containing heavy carbon and oxygen, with varying amounts of metamorphic fluid. Many samples containing heavy carbon also preserve oxygen isotope compositions similar to pre-metamorphic values. This is good evidence for a pre-metamorphic origin of the heavy carbon isotope signature, as any process involving a carbonate during metamorphism is likely to decrease its $\delta^{18}O$ value. Exchange with other silicates,

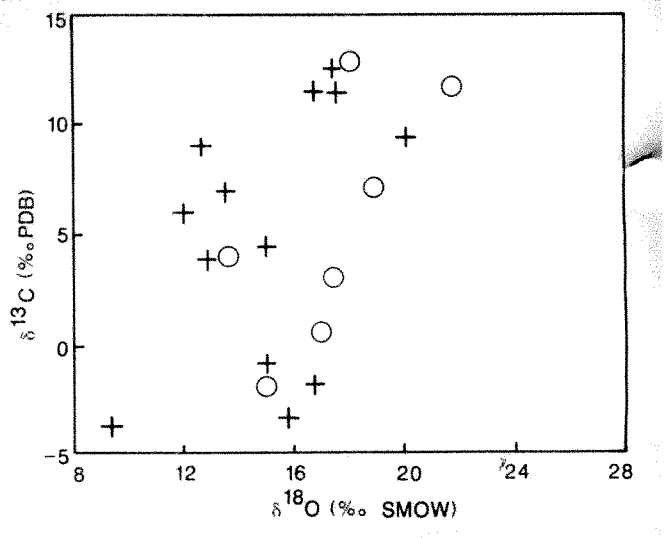

Fig. 1 $\delta^{13}C$ (relative to PDB) versus $\delta^{18}O$ (relative to standard mean ocean water (SMOW)) for analysed calcites. Circles represent Loch Maree data, and crosses are Gairloch data.

exchange with an infiltrating fluid and devolatization reactions are all likely to cause decreases in $\delta^{18}O$. Hence high-$\delta^{18}O$ calcites must have been little affected by metamorphic processes and should therefore preserve pre-metamorphic $\delta^{13}C$ (see, for example, ref. 6). In general, it is hard to conceive of metamorphic processes likely to increase $\delta^{13}C$ of a marble by more than a few parts per thousand. Metamorphism normally results in decreases in calcite $\delta^{18}O$ and $\delta^{13}C$ (ref. 6). We conclude that marbles from the Lewisian had $\delta^{13}C$ values of ~12‰ over a large area and that this signature is attributable to some synsedimentary process.

During the Phanerozoic, carbon isotope variations in marine limestones did not generally deviate by more than about 4‰ from the present $\delta^{13}C$ value of 0‰ (ref. 7). There is evidence, however, that during certain periods within the Precambrian many limestones had $\delta^{13}C$ values in excess of +5‰ (refs 8–12). A summary of carbon isotope variations in Precambrian marine limestones is shown in Fig. 2. Further data, not plotted in Fig. 2, exist for the period 1.0–0.5 Gyr which supports the occurrence of a series of positive excursions in seawater $\delta^{13}C$ at this time[12]. Of particular note are the extraordinarily ^{13}C-enriched marbles from the Lomagundi Province of Zimbabwe. Here dolomitic marbles associated with graphite-rich metasediments have isotope compositions of up to $\delta^{13}C = +12‰$. These marbles were deposited between 1.95 and 2.65 Gyr ago[1]. Recently, ^{13}C-enriched marbles with $\delta^{13}C$ of up to +12‰ have been found in Lofoten-Vesterålen, Norway. These were deposited between 1.8 and 2.1 Gyr ago in association with graphite schists and iron formations[13]. The marbles have experienced amphibolite facies metamorphism, but the heavy carbon isotope signatures have been attributed to pre-metamorphic processes on the basis of arguments identical to those above (ref. 2 and A.J.B. and A.E.F., manuscript in preparation). Heavy carbon isotope signatures have also been recorded in 2.0-Gyr-old marbles from Finland (ref. 8 and J. Karhu, personal communication) and in marbles of similar age from Soviet Karelia[14]. Interpretation is hampered by the poor resolution of the geochronological data (see Fig. 2), but it appears that ^{13}C-enriched limestones were particularly common about 2.0 Gyr ago. It is not clear whether this represents a single positive excursion in $\delta^{13}C$ or a series of excursions analagous to those described for the period 1.0–0.5 Gyr (ref. 12). The latter excursions are associated with changes in the $\delta^{34}S$ of marine sulphate. This may be explained in terms of maintenance of the redox cycle of the hydrosphere by the carbon and sulphur cycles[15]. A sulphur isotope excursion has not been

observed for the 2.0-Gyr $\delta^{13}C$ anomaly[11,16]. At this time, however, the oxygen cycle may have been controlled by coupling between the carbon and iron cycles rather than between the carbon and sulphur cycles[15]. Secular variations in the carbon isotope ratios of marine carbonates between 1.0 and 2.0 Gyr are as yet poorly constrained; this may be a period during which sea water had 'normal' carbon isotope signatures close to 0‰.

The 2.0-Gyr excursion could be attributed to a number of processes. It could represent a worldwide excursion in seawater carbon isotope composition, excursions in sea water restricted to localized basins or the operation of some process restricted to particular intervals within the geological record. Today, ^{13}C-enriched carbonates may be deposited from CO_2 derived from zones of anaerobic diagenesis[17] or from hot spring waters[18]. The former process is unlikely to explain the isotope systematics of carbonate-rich sediments and the latter is unlikely to explain the deposition of carbonate over large areas, restricted to particular intervals of geological time. Moderately ^{13}C-enriched carbonates are found in some evaporitic environments[19]. Evaporites are not, however, restricted to particular intervals within the Precambrian[20]. Sedimentary sulphates do occur as accessory minerals in some Lewisian and Lomagundi sediments, but extensive evaporite deposits are absent.

The carbon isotope compositions of marine limestones are generally controlled by the proportion of seawater carbon that passes into limestones and the proportion that passes into organic carbon (see, for example, refs 12, 21). Increases in the amount of organic carbon deposited can lead to positive $\delta^{13}C$ excursions, as during Phanerozoic anoxic events (ref. 22, for example). High-$\delta^{13}C$ limestones from Lomugundi, the Lewisian and Lofoten-Vesterålen are associated with organic-carbon-rich metasediments. We suggest therefore that the positive anomaly is associated with an increase in organic-carbon deposition in sediments either on a worldwide basis or within many marginal basins. Return to the deposition of carbonates with more normal isotope compositions could have been achieved by the operation of a number of buffering processes, perhaps including an increase in the rate of organic-carbon recycling within the oceans.

It appears that high-$\delta^{13}C$ carbonates deposited ~2 Gyr ago were deposited approximately synchronously with the transition from a reducing to an oxidizing hydrosphere[20]. The end of uraninite-conglomerate deposition and changes in the oxide minerals found in fluvial deposits and palaeosols suggest that a large increase in quantities of atmospheric oxygen occurred between 2.5 and 2.0 Gyr ago[20]. The maximum rate of deposition of iron formations occurred in this period, but declined sharply thereafter, reflecting the transition to a more oxidizing environment[20]. It has been suggested that similar increases in atmospheric oxygen accompanied the deposition of ^{13}C-enriched limestones between 1.0 and 0.5 Gyr (ref. 12). Increases in atmospheric and oceanic oxygen at about 2.0 Gyr are likely to have been accompanied by major changes in the carbon cycle. We suggest that increased oxygen contents of the oceans were produced and were accompanied by an increase in organic productivity. The increased oxygen content of the atmosphere may have been the direct result of an increase in the population of photosynthesizing bacteria[23]. Increasing oceanic oxygen contents may also have enabled the further exploitation of certain oceanic environments and enlargement of the biomass. This increased organic productivity, in the absence of compensating increases in the rate or organic-carbon recycling, would have increased rate of organic-carbon deposition and resulted in the deposition of high-$\delta^{13}C$ limestones.

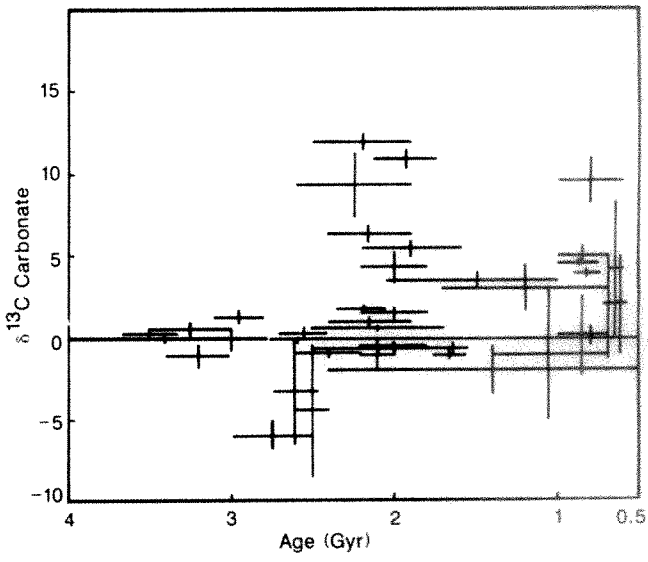

Fig. 2 $\delta^{13}C$ of Precambrian sedimentary carbonates plotted against age of deposition. Data from refs 1, 2, 8, 9, 10, 11 and this study.

Relationships between pre-rift structure and rift architecture in Lakes Tanganyika and Malawi, East Africa

J. Versfelt* & B. R. Rosendahl

Project PROBE, Department of Geology, 310 Old Chem, Duke University, Durham, North Carolina 27706, USA

Continental rift systems are rips in plates caused by focusing of extensional stresses along some zone. In the same way that tensile cracks in the side of a brick building generally follow the mortar between bricks, rifts initially follow the weakest pathways in the pre-rift materials. There has even been a suggestion that the occurrence of rifts is controlled by pre-rift structure[1-3], although many workers do not subscribe to such direct causality. The relationships between pre-rift structure and rifting tend to become progressively more obscure as the scale of examination decreases, mainly because unravelling these relationships requires more precise information about the architecture of rifts, the nature of the pre-rift fabric and about the principal axes of stress than is generally available. Recent work by Project PROBE on the Tanganyika[4-15] and Malawi Rift Zones[12,16-22] permits crucial aspects of these inter-relationships to be examined in a more rigorous fashion than was previously possible. In this region, the rift system follows Proterozoic mobile belts and bifurcates around the Tanganyika craton, which apparently has acted as a resistant core (Fig. 1). Here we show that the fundamental architecture of the Tanganyika and Malawi Rift Zones (that is, the positioning of half-grabens, the way they link together, and the types and trends of linking structures) is strongly influenced by the nature of the pre-rift fabric and the orientation of the stress field.

Fault-pattern maps of the Lakes Tanganyika and Malawi Rift Zones are shown in Fig. 2, and generalized structure maps in Fig. 3. Both rift zones are composed of basins that are asymmetric in cross-section. The deep sides of the basins are bounded by border-fault systems (BFSs), along which subsidence tends to be cumulatively greater than elsewhere in the basin. In plan view the BFSs are mapped as slightly to markedly arcuate. Subsidence varies along BFSs, creating an asymmetry in the strike direction that complements the dip asymmetry. These asymmetric basins, or 'half-grabens'[8,11,23], link together in various ways.

The general theme of linking is that adjacent half-grabens are offset from each other in the strike dimension and face in opposite directions, often resulting in a roughly sinusoidal alternation of dip polarities along strike[4-8]. The best examples of this occur between the Livingstone-Usisya and Usisya-Metangula half-grabens of Malawi. The BFSs of the Usisya and Metangula half-grabens are only slightly offset from each other and the BFSs of the Livingstone and Usisya units virtually merge end-to-end (Fig. 3). One variation on this general theme is for half-grabens to face each other imperfectly, like a pair of vertically skewed parentheses (this is exemplified by the North and East Kigoma half-grabens of Tanganyika, Usisya and the

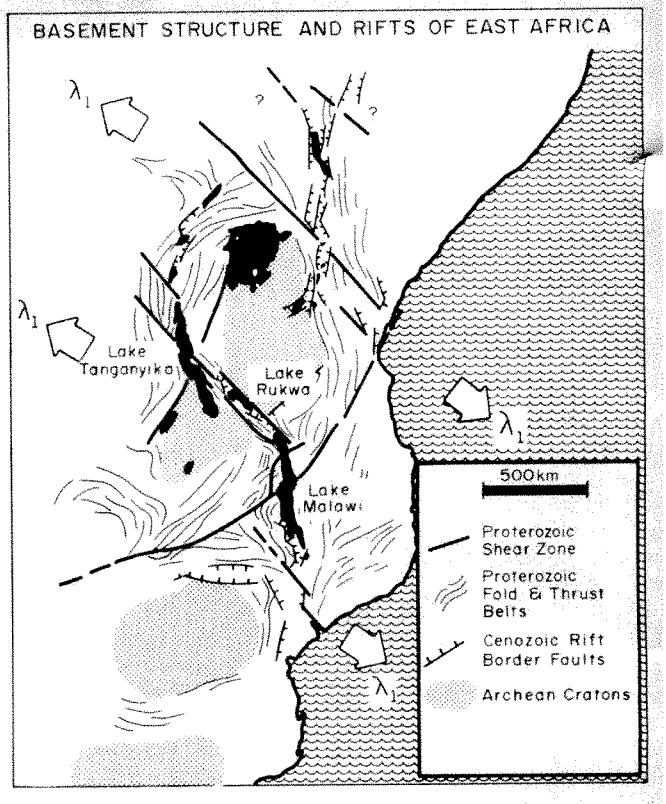

Fig. 1 Tectonic framework of East Africa.

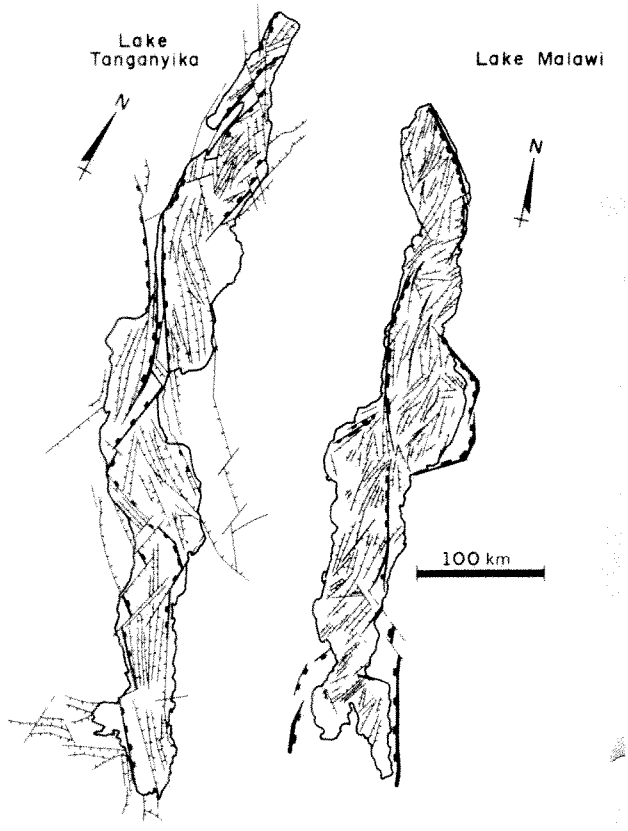

Fig. 2 Detailed fault-pattern maps of the Tanganyika and Malawi Rift Zones, derived from analyses of multifold seismic data. Faults shown are those which offset acoustic basement. Heavy hachured faults refer to master border-fault complexes.

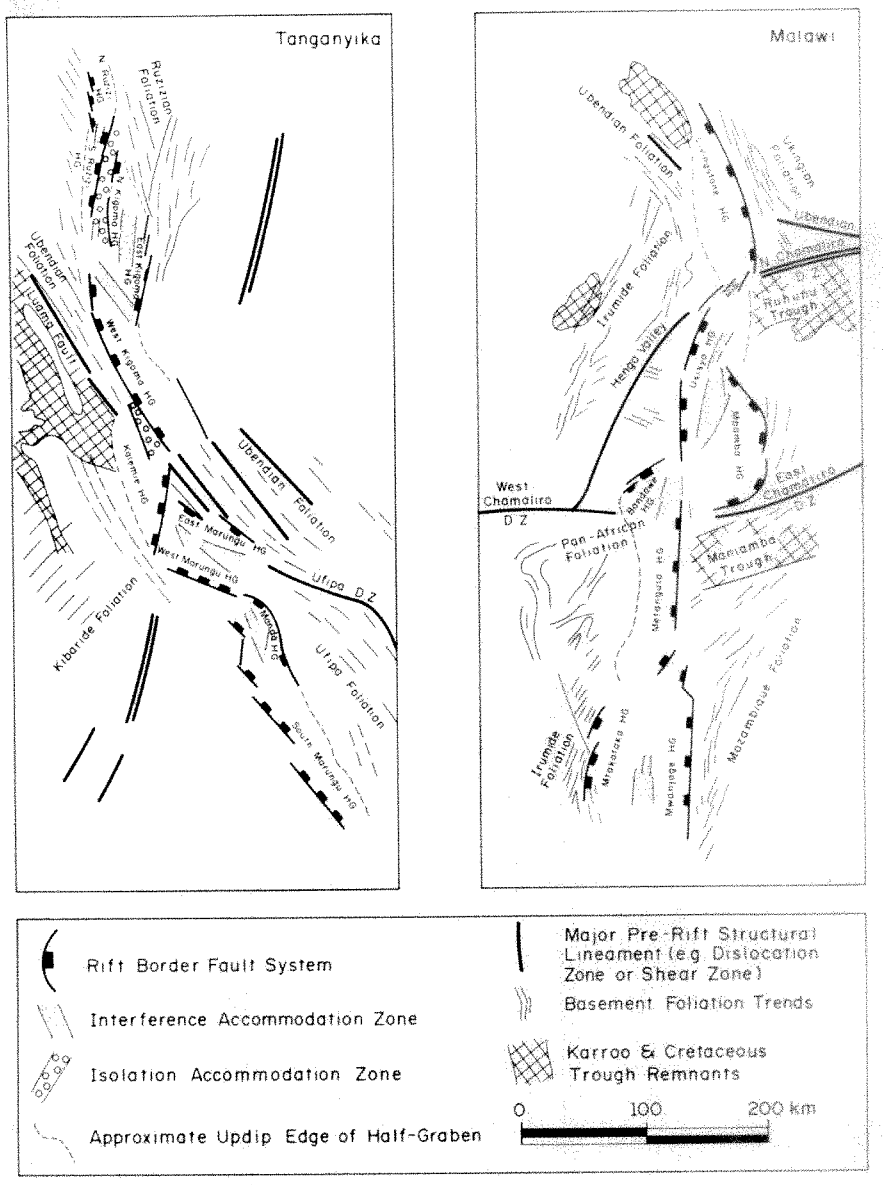

Fig. 3 Generalized structure maps of the Tanganyika and Malawi Rift Zones superimposed on pre-rift structure. The Tanganyika fabric is that described by McConnell and shown in the UNESCO maps of Africa[1-3,41,42], supplemented with more recent mapping and satellite image analyses[12]. The Malawi fabric is derived from Bloomfield[43] and an analysis by Versfelt[12].

Mbamba half-graben of Malawi). The resulting linking structure is called an interference accommodation zone (INAZ)[11]. Tanganyika has about five such zones, and Malawi has four (Fig. 3). INAZs are usually basement highs along which deformation is concentrated. The exact origin of INAZs is uncertain but their structural relief and tendency to act as strain guides suggest that they express a space limitation, or competition for space, associated with the facing geometries[8,11]. Another linking arrangement is for half-grabens to face in opposite directions, like a pair of reversed parentheses, with a backbone of relatively unsubsided terrain separating the half-grabens[4-8]. This linking structure is termed an isolation accommodation zone (ISAZ)[11]. Two ISAZs are mapped in Tanganyika, but there are none in Malawi.

The pre-rift structure of East Africa can be divided into the following categories: cratons and mobile belts, earlier rift troughs, transcontinental dislocation zones and basement foliations[12]. Cratons are thick, stable, Archaean nuclei composed of greenstone belts sandwiched between ensialic plutons. Mobile belts are gently arcuate, highly folded Proterozoic rocks that wrap around cratons[24]. Earlier rift troughs refer to remanents of Permo-Triassic- to Cretaceous-age rift basins. The Ruhuhu and Maniamba Karroo troughs in Malawi trend nearly perpendicular to the lake axis, whereas the Cretaceous trough at the north end of the lake runs essentially parallel to the lake. In Tanganyika, a Permo-Triassic basin trends sub-parallel to the southern half of the lake and intersects the lake near the central dog-leg (Fig. 3). Transcontinental dislocation zones (TDZs) refer to major sutures in the pre-rift crust that have been activated during various African orogenies and rifting episodes. They generally lie within mobile belts. The most important TDZs in Malawi are the West, East and North Chamaliro zones and the Henga Valley zone, all of which constitute local segments of the Schliesen–Mwimbeshi–Chamaliro TDZ (Figs 1 and 3)[25,26]. This TDZ may have represented a dextral shear zone during the Pan-African orogeny[25], and a sinistral strike-slip fault zone during Karroo times[26]. The most important TDZ in Tanganyika is the northwest-trending Rukwa dislocation zone (Fig. 1), which connects with the Ufipa zone and Luama Fault (Fig. 3). This zone may have originated during the Ubendian orogeny as a sinistral shear zone[1,27] and have been reactivated during Permo-Triassic rifting[27-29]. Basement foliation refers to the overall fabric of the pre-rift rocks and includes local faults and fractures, axial planar fabrics, trends of igneous bodies, contrasts in metamorphic grades, schistocity and compositional layer boundaries. Generally, this foliation is the local fabric of the mobile belts in which Tanganyika and Malawi are situated.

Estimates of the regional direction of extension in the Tanganyika–Rukwa–Malawi system range from northwest–southeast through southwest–northeast, but the evidence for

northwest–southeast opening is overwhelming. This extension direction is supported by numerous earthquake studies (refs 30–35 and R. M. Hamilton, unpublished report) and mapping and satellite image analyses (J. Chorowicz, preprint)[12,26–29,38–43]. Such an opening direction is essentially parallel to the Rukwa, Aswa and Zambesi lineaments, all of which presumably would serve as transform faults[11,27–29] with continued northwest–southeast opening.

The inter-relationships between rift architecture and pre-rift structure in Tanganyika and Malawi are shown in Fig. 3. The key relationships are summarized in Fig. 4. The most significant relationship is that alternations in half-graben polarity tend to occur where the transcontinental dislocation zones intersect the rift zones. In Malawi the switch in dip asymmetry between the Livingstone and Usisya half-grabens occurs where the Henga Valley–North Chamaliro TDZs cross the rift zone. The polarity switch between the Usisya and Metangula half-grabens occurs where the West Chamaliro–East Chamaliro zone crosses the rift. In Tanganyika the polarity reversal between the West Kigoma and Kalemie half-grabens occurs where the Rukwa–Ufipa–Luama TDZ intersects the rift[9,10,15]. All three of these intersections and polarity changes are associated with major kinks in the rift zones.

Not all alternations in half-graben polarity are associated with known TDZs, although all known TDZs are associated with alternations. For example, the reversal between the North and South Ruzizi half-grabens in northern Tanganyika (Fig. 3) does not correlate with any known pre-rift dislocation zone. Whether TDZs cause adjacent half-grabens to alternate polarities or whether they simply offer a convenient place for such switch-overs to occur is not certain. We favour the mechanical convenience hypothesis, but readily acknowledge that TDZs could fundamentally alter rift dynamics under certain conditions.

The orientation of a TDZ relative to the rift axis may be related to the type of linking structure observed. The Henga Valley–North Chamaliro dislocation zone in northern Malawi is oriented nearly perpendicular to the inferred extension direction, whereas the Rukwa–Ufipa–Luama TDZ in Tanganyika is essentially parallel. In the latter case, the border fault systems of the adjacent half-grabens splay off the TDZ[9,10,15] and become more orthogonal to the direction of extension with increasing distance from the TDZ (Fig. 4). In the northern Malawi example, the BFSs also peel off the TDZ, but become more parallel to the extension direction with increasing distance from the TDZ. In the central Malawi case, the Usisya and Metangula BFSs essentially die out as they approach the TDZ at right angles. Here, the extension direction is oblique to both the BFS and the TDZ. These differences may explain the different linking structures observed between the Tanganyika case (ISAZ), the northern Malawi example (very small, narrow INAZ) and the central Malawi situation (broad, diffuse INAZ). Admittedly, the morphology of the latter may also be partly due to the facing geometry of the Bandawe–Mbamba half-graben.

The role of earlier episodes of rifting on the development of the Tanganyika and Malawi Rifts is difficult to isolate from that of the TDZs because there is a close spatial association between these features. Evaluation of existing data suggests, however, that the rift architectures shown in Fig. 3 would not be significantly different if the earlier rift troughs were not present.

As stated earlier, both the Tanganyika and Malawi Rift Zones generally follow the basic 'grain' of the mobile belts. More surprising is the close association of INAZs with pre-rift fabric (Figs 2 and 3). This relationship is not sensitive to INAZ fault orientations relative to extension direction. Apparently, the fabric of the Proterozoic mobile belts exerts a very strong influence on the orientation of the structures that define INAZs. Careful inspection of Fig. 3 shows that INAZs occur commonly at the intersections between pre-rift fabrics of different trends. The INAZs that divide the North, East and West Kigoma half-grabens of Tanganyika are an example. In effect, INAZs divide different basement lithologies and follow the orientation of one of them. This may offer a clue to the origin of INAZs and perhaps also to the factors determining the geometries of facing half-graben.

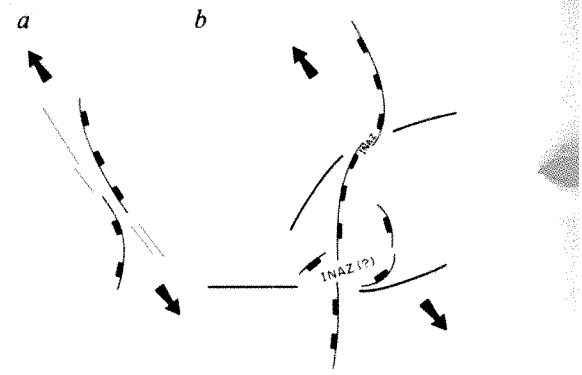

Fig. 4 Selected linking architectures in the Tanganyika (*a*) and Malawi (*b*) Rift Zones superimposed on pre-rift structure. Arrows denote inferred direction of extension for the East African Rift. *a*, Kavala Island model of ISAZ-linked half-graben alternation; the pre-rift shear zones and/or fabric are oriented sub-parallel to the primary extension direction. *b*, Malawi model of INAZ-linked half-graben alternation; the pre-rift shear zones and/or fabric are oriented sub-perpendicular to the primary extension direction.

There also seems to be a general parallelism between the trends of border-fault systems, internal faults and the pre-rift grain, with a few exceptions. One exception occurs where BFSs splay off TDZs and cross pre-rift fabric, as is the case for the West Kigoma and Kalemie BFSs. Another exception is the north–south linear portion of the Usisya–Metangula BFS pair, which seems to cut across the earlier grain. A third exception occurs in the Livingstone half-graben of northern Malawi, where the infrastructure tends northeast–southwest, at about 60° to the trend of the BFS and to the Ubendian and Ukingian foliations (Figs 2 and 3). In spite of the broad correlation between the trends of BFSs and pre-rift fabric, BFSs do not seem to follow major lithological contracts for appreciable distances[18]. This role seems to be reserved for INAZs.

The architectural concepts described for the Tanganyika and Malawi Rift Zones seem to have wide applicability[4,11], suggesting that the relationships described herein probably apply elsewhere. We speculate that the polarity reversals that occur in such rifted environments as the Gulf of Suez, Rio Grande Rift and Mid-Continent Rift of North America[4] are related to the positioning of transcontinental dislocation zones; we hope that this hypothesis will be tested in the future.

Facultative viviparity in a thrips

Bernard J. Crespi*

Museum of Zoology and Department of Biology,
University of Michigan, Ann Arbor,
Michigan 48109-1079, USA

The absence of species that show facultative variation in reproductive mode within populations[1–4] has thus far severely hindered study of the selective pressures associated with oviparity and viviparity. Here I report that females of the mycophagous thrips *Elaphrothrips tuberculatus* (Insecta: Thysanoptera) are facultatively viviparous and produce male offspring by viviparity and female offspring by oviparity. Individual females can switch between the two reproductive modes. Females produce fewer offspring when viviparous than when oviparous, but the survivorship of viviparous offspring is sufficiently high that the average number of pupal offspring produced by females in each mode is similar. Facultatively viviparous thrips provide the first experimental systems for analysing the behavioural, ecological and physiological causes of variation in reproductive mode.

Elaphrothrips tuberculatus is a winged thrips about 5 mm long that lives on clusters of hanging dead oak leaves and feeds on fungal spores[5,6]. In southern Michigan, it overwinters as adults of both sexes in leaf litter, emerges in mid-April to mid-May, and undergoes two generations per year. Observations of breeding adults show that some females deposit eggs one at a time, over a 1–3-week period, onto an egg mass which they defend against potential egg predators[7]. By contrast, other females do not lay eggs, although they are gravid during any given breeding period. Dissection of gravid females demonstrates that oviparous females contain four ovarioles with each ovariole comprising enlarging, undeveloped oocytes arranged linearly. Viviparous females contain two clusters of embryos in increasingly advanced stages of development distally, such that fully gravid females contain one or several fully developed first-instar larvae. Two lines of evidence indicate that this variation among breeding females represents a reproductive dimorphism rather than stages of egg retention: first, the ovaries of more than 738 dissected females were of one or the other type, and second, gravid females isolated in Petri dishes deposit either a mass of undeveloped eggs that they guard ($N = 20$) or several first-instar larvae (with no trace of chorion visible) ($N = 53$). Larvae or eggs are often deposited within 24 h of isolation.

If reproductive mode is under facultative female control, then individual females may be capable of switching between oviparity and viviparity. *E. tuberculatus* females normally reproduce once during the one-month spring generation, but the summer generation lasts for about two months, which allows sufficient time for multiple bouts of reproduction[6]. Allowing females to breed individually in summer on dead oak leaves in nylon bags so as to record their reproductive mode (by noting the presence of egg masses and the presence and sex of offspring[6,8]) showed that about one-third of females switched reproductive mode in 1986 (21 both modes, 15 viviparous, 20 oviparous) and 1987 (20 both modes, 19 viviparous, 12 oviparous). *E. tuberculatus* is apparently the only animal species known in which individual females are capable of switching between oviparity and viviparity.

Because reproductive mode is under facultative female control in this species, variation in mode may be associated with variation in measurable aspects of females and their environments. The body sizes (lengths of the fore-femora) of viviparous and oviparous females did not differ during the spring generation, but during the summer generation viviparous females were substantially larger than oviparous females[9]. To determine whether or not aspects of seasonality affect female reproductive mode, I allowed individual females from both the spring and summer generation to breed on both spring- and summer-generation dead oak leaves (summer leaves have died within the past few months, whereas spring leaves died in the preceding year). The only treatment in which females were viviparous (5 of 14) was summer females on summer leaves; no females were viviparous in the spring females/spring leaves treatment (0 of 15), the spring females/summer leaves treatment (0 of 13), or the summer females/spring leaves treatment (0 of 14) ($G = 15.4$, $P < 0.005$). These data suggest that a proximate cause of viviparous reproduction involves interaction between a female's generation and the generation of the leaves that she inhabits.

All thrips are believed to have a haplodiploid genetic system, such that haploid males develop parthenogenetically, and diploid females develop from fertilized eggs[10,11]. Sexing of first-instar larvae[6,8] showed that, in *E. tuberculatus*, all of 1,051 newly hatched larvae from eggs laid by 42 females were female, and all of 202 larvae produced by 32 viviparous females were male. These data indicate that mode of reproduction is invariably associated with offspring sex. But sperm were seen clearly in the spermathecae of 134 (87%) of 154 dissected viviparous females.

Because females produce single-sex broods, individual breeding females can be considered as units of investment in one sex or the other[6]. Thus, if females are equal in resources available for breeding, then frequency-dependent selection on sex allocation[12] should favour a population-wide proportion viviparity (that is, a sex-allocation ratio) of 50%. In *E. tuberculatus*, deviations from 50% viviparity (Table 1) may be caused by a sex difference in the degree of competition among siblings between spring and summer[6] and partial bivoltinism with variation between generations in the reproductive value of the two sexes[13]. Moreover, if the large size of viviparous females relative to oviparous females in summer represents a difference in resources available for investment, then the summer sex-allocation ratio is more male biassed than it would appear to be from the proportion of females in each reproductive mode.

The association between offspring sex and reproductive mode in *E. tuberculatus* allows testing of a central hypothesis concerning the evolution of viviparity: that viviparous females should produce fewer offspring than oviparous females, but that these

* Present address: School of Biological Science, PO Box 1, University of New South Wales, Kensington, New South Wales 2033, Australia.

Table 1 Fecundity of oviparous and viviparous females and the relative survivorship of their offspring

Season	Pupal sex ratio	Mode	Percentage females in mode	Average fecundity	Relative survivorship
Spring	0.19	Viviparity	0.25	21.5	1.4
		Oviparity	0.75	43.7	1.0
Summer	0.58	Viviparity	0.55	13.5	2.1
		Oviparity	0.45	26.1	1.0

Within each sex, the number of pupae present at the end of a generation should be equal to the number of females in the appropriate reproductive mode during that breeding period, multiplied by their average fecundity, multiplied by the survivorship of their offspring from egg laying or larviposition to the pupal stage. Pupal sex ratio was calculated by collecting pupae during the spring and summer generations, allowing them to become adult, and sexing the adults (see refs 6, 9). The spring pupal sex ratio is the average for 1984 (0.19 male, $N = 9,709$), 1985 (0.16 male, $N = 6,617$), and 1986 (0.21 male, $N = 3,158$), and the summer pupal sex ratio is the average for 1985 (0.69 male, $N = 483$) and 1986 (0.46 male, $N = 1,399$) (ref. 6). The percentage of females in each mode was determined by dissecting females and inspecting their ovaries (see refs 6, 9); the percentage for spring is the average for 1986 (0.26 viviparous, $N = 449$) and 1987 (0.24 viviparous, $N = 902$), and the percentage for summer is data from 1986 ($N = 645$). Oviparous female fecundity was measured in spring by counting the number of eggs in complete clutches and taking the average for 1985 (39.5 ± 8.7, $N = 127$), 1986 (46.6 ± 9.4, $N = 121$), and 1987 (44.9 ± 9.9, $N = 145$) (refs 6, 7). In summer, oviparous female fecundity was measured by counting the number of eggs in completed and abandoned egg masses (26.1 ± 11.4, $N = 222$, data from 1986) (refs 6, 7). In spring, viviparous female fecundity was estimated by counting the number of first-instar larvae produced by individual viviparous females on 2–3 dead oak leaves in the field, dissecting the females near the end of the breeding period, counting the number of embryos in their abdomens, and adding these two numbers; these data (21.5 ± 5.4 offspring, $N = 20$ females) were taken in 1987 (ref. 6). In summer, viviparous female fecundity was measured by putting females individually on 2–3 dead oak leaves in nylon bags suspended in the field early in summer, allowing them to breed for about 2 months, and either: (1) counting the number of adult males that were produced by the females that were viviparous (15.0 ± 6.7, $N = 15$, data from 1986), or (2) removing and counting the larvae produced every two weeks for eight weeks (12.2 ± 6.9, $N = 18$, data from 1987) (ref. 6). The value used is the average for 1986 and 1987 (13.5 ± 6.8, $N = 33$). The relative survivorship, from the egg stage to the pupal stage, of offspring produced by oviparity is set arbitrarily to 1.0, and the relative survivorship of offspring produced by viviparity is obtained by multiplying through.

offspring should have higher survivorship[14]. In both generations, the average fecundity of viviparous females was about half that of oviparous females, but the survivorship of the offspring of viviparous females to the pupal stage was 1.4 times higher than that of the offspring of oviparous females in spring and 2.1 times higher in summer (Table 1). The contribution of offspring sex, rather than mode of development, to differences in survivorship is unknown. This hypothesis could be tested more directly using a thrips species, such as *Sporothrips amplus*, in which one sex (males) is produced by both oviparity and viviparity (unpublished data).

In vertebrates, correlates of viviparity include the presence of maternal care in related oviparous species[3,4] (which is considered as an alternative adaptation to harsh conditions for eggs[15]) and the presence of physical defences such as venom or predatory habits (which are presumed to reduce mortality in females encumbered by embryos[4,16]). In *E. tuberculatus*, maternal care is clearly an alternative to viviparity, and females use a potent defensive secretion, juglone, to repel predators such as salticid spiders (Blum *et al.*, unpublished data). Thrips apparently show a complete range of variation in reproductive mode, including fully oviparous, egg-retaining, facultatively viviparous, and fully viviparous species[17–19]. Comparative analysis of the correlates of reproductive mode among thrips, coupled with experimental analysis of facultatively viviparous species, should elucidate the selective pressures associated with the two modes of reproduction. Moreover, the presence of facultative viviparity in this taxon suggests that viviparity sometimes originates as a facultative alternative in an otherwise oviparous population, rather than by population-wide directional selection for egg retention.

I thank R. D. Alexander, D. G. Blackburn, R. Crozier, W. D. Hamilton, R. Nussbaum, J. Seget and L. Vawter for helpful comments, and R. Nussbaum for permission to work at the E. S. George Reserve.

A mutation that changes cell movement and cell fate in the zebrafish embryo

Charles B. Kimmel, Donald A. Kane, Charline Walker, Rachel M. Warga & Mary B. Rothman

Institute of Neuroscience, University of Oregon, Eugene, Oregon 97403, USA

The study of developmental patterning has been facilitated by the availability of mutations that produce changes in cell fate, in animals such as *Caenorhabditis elegans*[1,2] and *Drosophila melanogaster*[3,4]. We now describe a zygotic lethal mutation in the zebrafish, *Brachydanio rerio*, that also changes how particular embryonic cells develop. Severe pattern deficiencies are observed that are restricted to a single body region, the trunk. The mutation may directly affect mesoderm, as somites do not form in the trunk. Head and tail structures, including tail somites, are relatively undisturbed. The earliest detected expression of the mutation is during gastrulation, when movements of mesodermal cells occur incorrectly. We injected prospective trunk mesodermal cells with lineage tracer dye and observed that in mutants these cells may enter a new body region, the tail, and there may express a new fate appropriate for the changed position.

The mutation, *spt-1(b104r1)*, nicknamed 'spadetail', was initially discovered among the parthenogenetic progeny of a

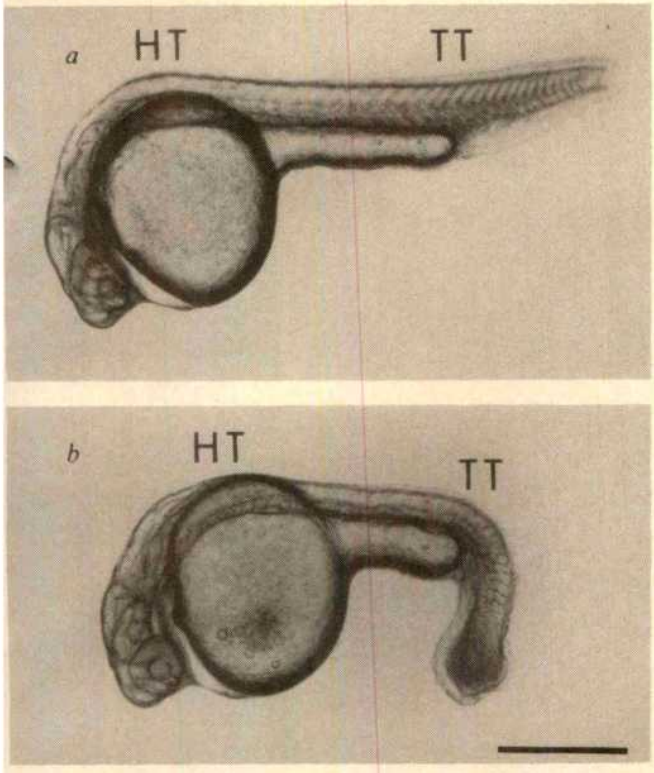

Fig. 1 Live wild-type (*a*) and homozygous *spt-1*(*b104*) mutant (*b*) zebrafish embryos at 24 h (all times are in hours postfertilization at 28.5 °C). Genetic nomenclature for zebrafish is adapted from that for *C. elegans*[17]; *spt-1* indicates the locus of the mutation, and *b104* is the allele. HT: region of transition between the head and trunk, at the level where the anterior-most somites are normally observed. These somites are missing in the mutant, and trunk paraxial (segmental plate) mesoderm is deficient. TT: region of transition of the trunk and tail, at the anus, that in the mutant marks the position of a severe kink of the body and the restoration of somites. The enlarged tail bud of the mutant contains cells that eventually degenerate. (The designation *spt* refers to this prominent phenotype, termed by us the '*sp*ade*t*ail'). Scale bar, 400 μm.

single heterozygous female. The origin of the mutation is unknown. Mutants were identified by the changes in appearance of the embryo shown in Fig. 1. The phenotype is zygotic recessive, and mutants survive for less than one week of development. The mutation segregates as a single locus, and is fully penetrant; about one-quarter (410/1,660) of embryos obtained from crosses between heterozygotes were mutant, and about one-half (222/437) of haploid embryos obtained[5] from heterozygous females were mutant. As a step towards characterizing the locus genetically, we have recently identified a putative allelic γ-ray-induced mutation, *b141*, by its failure to complement the original one, *b104*. We have not yet studied the phenotype of *b141* homozygotes however, and describe here the *b104* mutation only. We concentrate on the earlier changes, which are likely to be more useful for our eventual understanding of *spt-1*+ function.

Development seems normal before gastrulation, and during its onset. By six h (hours after fertilization at 28.5 °C) both wild-type embryos and *spt-1* mutants have begun epiboly[6], and have formed a germ ring and embryonic shield[7]. The presence of these structures suggest that early morphogenetic cell movements occur in mutants, in particular the involution of mesoderm (ref. 8; R.M.W. and C.B.K., manuscript in preparation). After 7–8 h cells accumulate abnormally at the dorsal side of the gastrula to produce a transient swelling, whose anterior–posterior level corresponds approximately to the region of transition between the prospective head and trunk (HT; Fig. 2*a*, *b*). As epiboly is completed at 10 h, cells accumulate at a

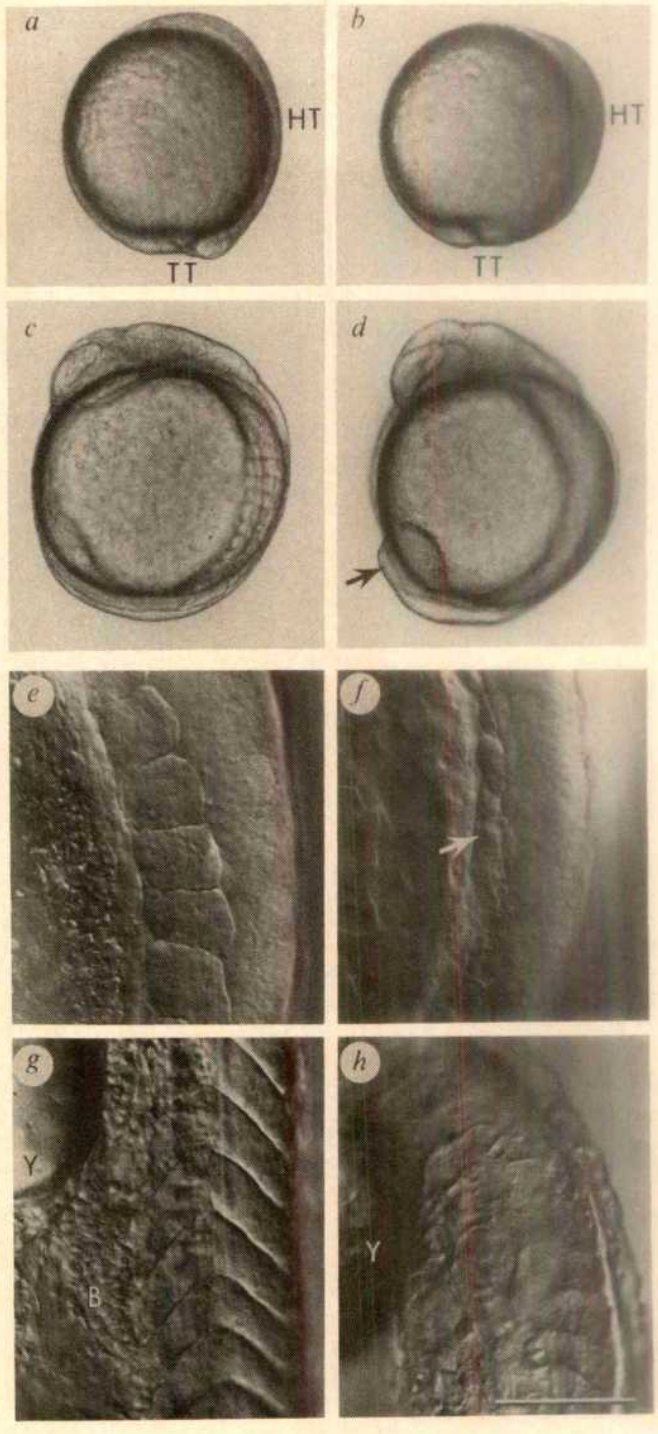

Fig. 2 Morphogenesis in living wild-type (left panels) and *spt-1* mutant embryos (right panels). Left side views with anterior to the top. *a*, *b*, Wild-types and mutants at completion of epiboly (closure of the yolk plug) at 10 h. The HT swelling was first observed in this mutant (*b*) at 7 h and the TT swelling has just appeared. *c*, *d*, Wild-type and mutant early tail bud embryos at 13.5 h. Trunk somites are visible in the wild-type (*c*), but are not present in the mutant (*d*), which by this stage has developed a very prominent tail bud (arrow). *e*, *f*, Nomarski interference contrast views of the developing trunk at 13.5 h. Somites are well-formed in the wild-type (*e*). The mutant (*f*) paraxial mesoderm (arrow) is very deficient; most of the tissue present is the spinal cord. *g*, *h*, Nomarski views of the TT region at 23 h. In the wild-type (*g*), V-shaped myotomes are present in both the trunk and tail. The anus (present but not visible at this plane of focus) is located just posterior to the yolk sac (Y), and near this location is a prominent cluster of developing blood cells (B). In the mutant (*h*), the first somites to appear are located over the posterior yolk sac. The myotomes that develop from them are poorly formed, whereas more posterior myotomes in the tail are better formed. The anus and blood cells are absent. Scale bars, 400 μm (*a*–*d*); 100 μm (*e*–*h*).

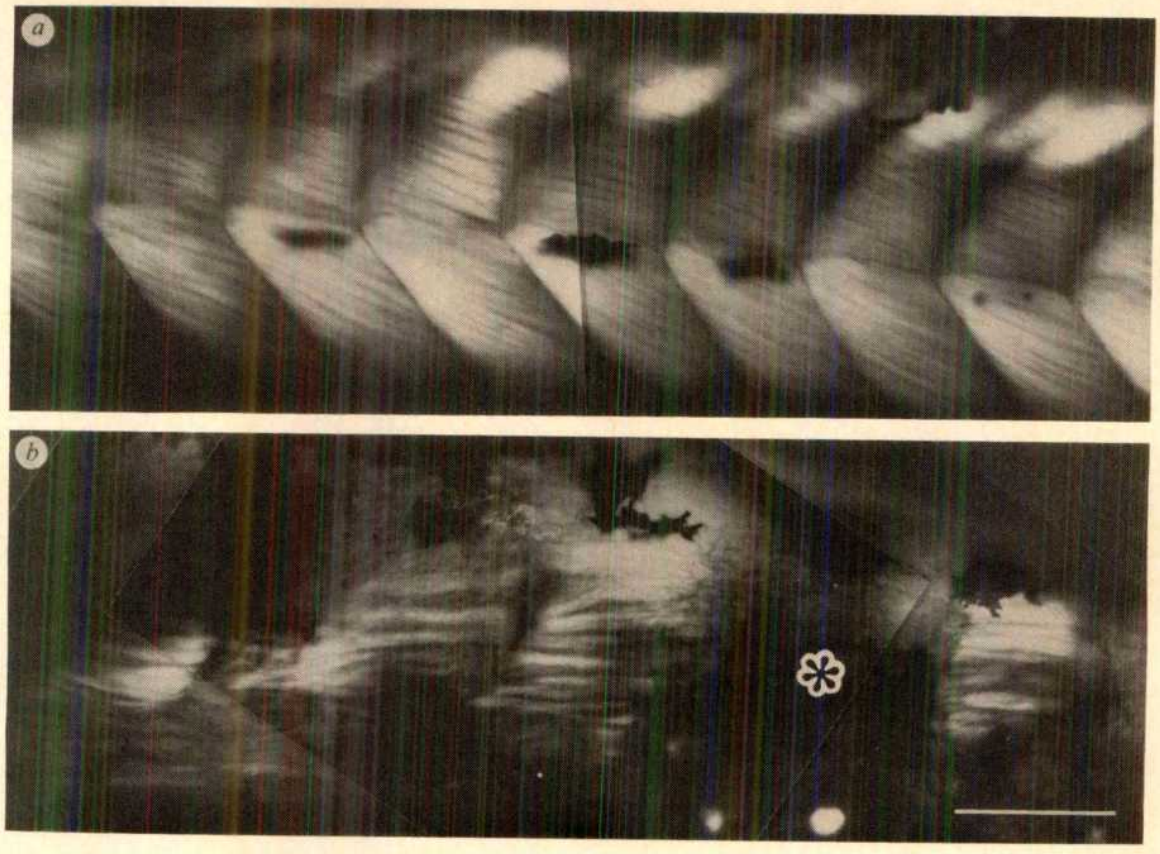

Fig. 3 Imperfect myotomes appear in the trunk in *spt-1* mutants. Left side views (dorsal to the top) of trunk segments in live embryos at 72 h. Polarized light, revealing patterning of birefringent myotomal muscle fibres. In wild-type embryos (*a*) the myotomes are regular V-shaped structures, and contain muscle fibres in orderly obliquely longitudinal orientations. The transverse myosepta (separating myotomes) and the horizontal myosepta (separating dorsal ventral parts of the myotomes) do not contain muscle, and are not birefringent. The view of a mutant (*b*) shows anterior trunk myotomes. The myotomes are of approximately normal length, and some muscle fibres are oriented longitudinally. Mutant trunk myotomes are not V-shaped, and horizontal myosepta are not detected. There are fewer muscle fibres than normal. Here, three anterior myotomes are followed by a myotome-long space with no muscle (*), and then by a single (isolated) myotome with severely disorganized fibres. Wild-type embryos normally have 15 myotomes anterior to the anus at this stage; this mutant had 6. Scale bar, 100 μm.

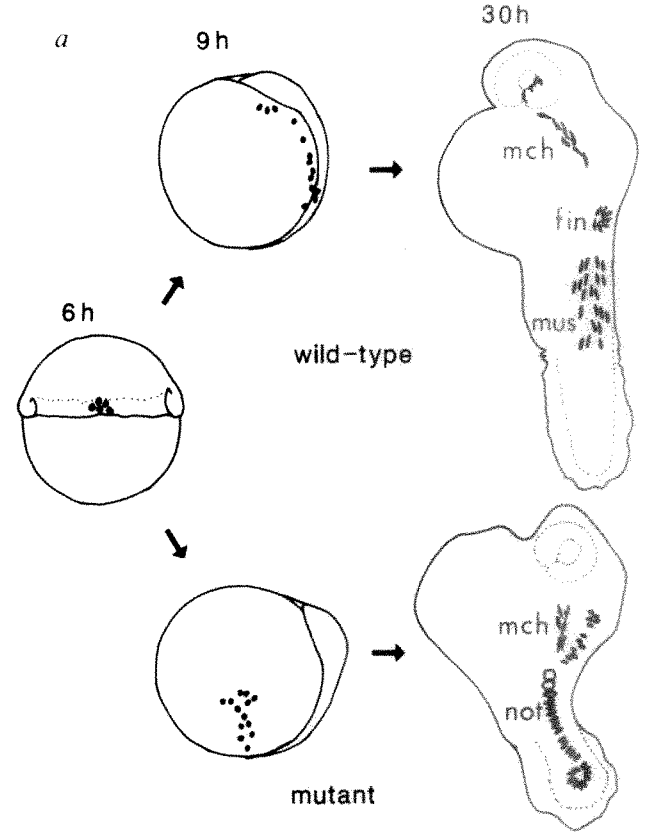

second incorrect location, ventral to the location of yolk plug closure, and approximately at the region of the juncture of the trunk and the tail (TT; Fig. 2*a*, *b*). The cells in this second swelling then seem to enter the tail bud, which remains abnormally large as the tail develops (Fig. 2*d*, arrow).

During tail bud stages, paraxial mesoderm is depleted in the trunk region of *spt-1* embryos (Fig. 2*c–f*). As trunk somites are forming in wild-type embryos (11–16 h; Fig. 2*e*), there are only scattered mesenchymal cells, and a few clusters of cells adjacent to the notochord in the mutants (Fig. 2*f*, arrow). The notochord and overlying spinal cord of the trunk at first seem to be formed normally, and then develop bends and kinks, as if they were compressed along the anterior–posterior axis, with the most severe kinks near both the HT and TT. Later some mutants fail to develop structures that normally arise near the HT, including the pronephric kidneys and pectoral fins on one or both sides. Blood cells and the anus, both normally arising near the TT, may also be missing. Structures that lie anterior to the trunk are invariably present however, and develop fairly normally, for example, the brain (including hindbrain neuromeres[9]), head sense organs, the series of branchial arches, the heart, and the pericardial hatching gland.

At the posterior in *spt-1* mutants, beginning at about the TT, paraxial mesoderm is more abundant and somite furrows are observed, roughly on schedule (15–16 h) with the formation of tail somites in their wild-type sibs (Fig. 2*g*, *h*). The earliest somites to form in mutants, those near the TT, are poorly shaped at first, but the shape of these somites is better at later times, and the posterior-most somites form rather normally at the outset. Eventually tail myotomes, derived from them, appear normal.

None of these changes are accompanied by an unusual amount of cell death. The only extensive cell death that we observe during embryogenesis in mutants is in the enlarged tail bud, beginning after the end of somitogenesis at about 30 h. First, a few necrotic cells can be identified in the tail bud with Nomarski optics[10], and by 48 h degeneration is massive. As a consequence, the abnormally swollen tail bud (Fig. 1) eventually disappears. The cell death in the mutant tail bud might be an entirely normal morphogenetic process that is magnified by its excessive number of cells. We have observed some corresponding necrosis in wild-type embryos, and similar patterns of cell death have been observed after completion of segmentation in the chicken[11] and leech[12].

We interpret the phenotype to mean that the mutation most severely affects development of the trunk of the body. The trunk does not seem to be deleted altogether as, for example, in *Drosophilia* gap mutants[13]. Some trunk structures, such as the notochord and the spinal cord, develop on a wild-type schedule. Moreover, a particularly interesting finding is that, later on, pattern regulation occurs in the trunk. Thus, before 24 h, myotomes become evident in this body region; that is, where no somites were present initially (Fig. 3). We have not determined the cellular origin of these myotomes. They are of about the correct axial length, but are not V-shaped as normal, and are sometimes separated from each other by myotome-long

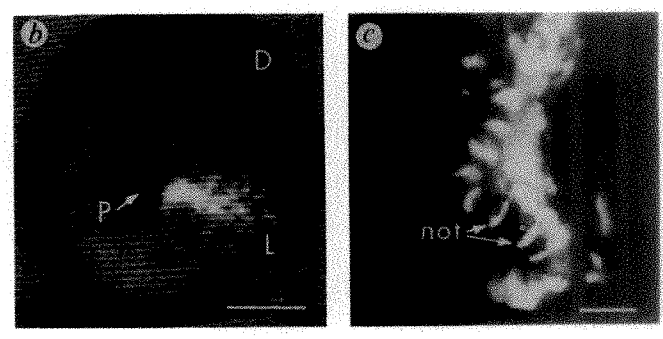

Fig. 4 *a*, Cell movements and fates of prospective trunk somitic mesoderm are changed in *spt-1* mutants. Single clones of fluorescently labelled cells that occupied the lateral germ ring at 6 h (early gastrula) were followed in wild-type (top) and mutant (bottom) embryos. The drawings were made from video time-lapse sequences of images (as in *b*), and show left-side views with anterior to the top. In the wild type the cells converge dorsally by 9 h, and by 30 h have formed mesoderm of the head and trunk, including mesenchyme (mch), pectoral fin bud (fin) and somitic muscle (mus). In the mutant, the cells moved posteriorly to populate the caudal trunk and the tail. They formed mesenchyme, notochord (not) and mutant tail bud. The clones in both the wild type and mutant also included neural and surface epithelial derivatives, which are not shown in these drawings. *b*, A posterior view of this mutant at 9 h, photographed from the face of the video-monitor. Fluorescence due to the tracer is superimposed on the bright-field image. The labelled cells have formed a stream from their starting position in the lateral equatorial region (L) towards the yolk plug posteriorly (P). In wild-type embryos, cells at the same starting location move dorsally (D). *c*, Fluorescence video micrograph of the tail (side view) of the same mutant at 30 h. Differentiating notochord cells (not) are labelled, distinguishable by their position and distinctive disk-shape. The individual cells are separated from one another by unlabelled notochord cells, among which they have intercalated earlier in development; the intercalations are a normal feature of morphogenesis[15]. In wild-type diploid embryos (as in *Xenopus laevis*[18]) the notochord of the head, trunk, and tail derives from cells located adjacent to the dorsal blastoderm margin of the early gastrula (C.B.K. and R.M.W., manuscript in preparation). In the work presented here we observed that dorsal marginal cells also gave rise to notochord in both mutant and wild-type haploid embryos (three out of five clones in mutants and three of 10 clones in wild types; at the gastrula stage these clones were all located along the dorsal one-third of the germ ring). Lateral and ventral marginal cells frequently gave rise to notochord in haploid mutants (five of 12 clones that were located along the lateral and ventral two-thirds of the germ ring in the gastrula), but not in wild types (none out of seven lateral and ventral clones). A more complete description of the mutant fate map is in preparation.

Methods. As mutants could not be identified until after the beginning of these experiments, we obtained a high proportion (50%) of mutants, by using haploid progeny[5] from *spt-1/+* heterozygotes. The mutant phenotype in haploids is similar to, and generally more severe than, that of homozygous diploids. Single clones were marked in a series of embryos at about 3 h (about the 10th cleavage division), by injecting cells near the blastoderm margin with rhodamine-dextran[19]. The position of the clones was mapped at early gastrula stage (6 h) using a Silicon-Intensified-Target (SIT) video camera to amplify fluorescence. In some cases of embryos bearing lateral clones (positioned at 90° from the embryonic shield[7]) the movements of the labelled cells were recorded during the next nine hours by time-lapse video microscopy. At 30 h we determined whether the embryos were wild-type or mutant, and scored the positions and the differentiated fates of the labelled cells[7]. Scale bars, 200 μm (*b*); 50 μm (*c*).

spaces that contain no muscle (Fig. 3*b*, *). The correct number of myotomes (30 pairs, including the trunk and tail) is also not restored in *spt-1* mutants. Counts in mutants range upwards from about 14.

Many of the defects in *spt-1* mutants may arise secondarily, cascading from an early pattern disturbance that involves the movements of specific cells during gastrulation. The HT and TT mark both the early locations of the abnormal cell accumulations and the later regions of most severe pattern defects. Paraxial mesoderm (prospective somite) is deficient between these same two regions (that is, in the trunk). These results indicated that those cells which should have migrated in the gastrula to form trunk paraxial mesoderm, moved incorrectly, leaving the trunk cell-deficient. We examined this possibility directly by using intracellularly injected tracer dye to observe the movements and eventual fates of the mutant cells. Previous work[7,14] established that the trunk somitic mesoderm normally arises by the dorsalwards convergence of cells from the lateral part of the germ ring at early gastrula stage. These cell movements seem to be similar in the haploid wild-type embryos studied here, and cell fates include trunk somitic muscle (Fig. 4*a*, top). However, in haploid *spt-1* mutants (Fig. 4*a*, bottom) cells at the same location in the early gastrula fail to converge dorsally; rather they move posteriorly, in an apparently active fashion (Fig. 4*b*), to enter the tail. The derivatives of such dislocated cells often include unusual fates for cells from this beginning location, in particular the notochord (Fig. 4*c*). Notochord of both the trunk and tail is normally derived from the dorsal side of the early gastrula, not the lateral side (see Fig. 4 legend). Thus the *spt-1* mutation can change the fate, as well as the movements of mesodermal cells. On the other hand, transfating was not invariably observed; in some mutants the dislocated cells formed tail muscle.

From the early expression of the mutant phenotype we infer that *spt-1+* must normally function during (or before) gastrulation. Our studies have not revealed the primary gene function, or which cells express the gene. The earliest observed change is in cell movement, and perhaps the mutation directly perturbs movement—affecting either the mesodermal cells themselves or their environmental navigation cues. If so, the observed changes in pattern and cell fate could follow secondarily, because final cell positions are changed. Alternatively, the mutation could act more cryptically: if cell commitments occur during gastrulation[15], the mutation could alter those commitments, and the cells move improperly as a consequence. Study of embryos that are genetically mosaic[16] for *spt-1*, as well as determining the primary function of the gene, should elucidate our

understanding of the relationships of cell movement, position and fate during embryogenesis in this vertebrate.

We thank Jay Mittenthal, Christianne Nusslein-Volhard, David Grunwald and Monte Westerfield for critical comments on earlier versions of this paper, and Reida J. Kimmel and Harrison M. Howard for technical assistance. This work was supported by the NIH and the Murdock Foundation.

Nerve growth factor regulates expression of neuropeptide genes in adult sensory neurons

Ronald M. Lindsay* & Anthony J. Harmar†

* Sandoz Institute for Medical Research, 5 Gower Place, London WC1E 6BN, UK
† MRC Brain Metabolism Unit, Royal Edinburgh Hospital, Edinburgh EH10 5HF, UK

Nerve growth factor (NGF) is a trophic molecule essential for the survival of sympathetic and sensory neurons during ontogeny[1]. The extent to which NGF is involved in the maintenance or regulation of the differentiated phenotypes of mature peripheral neurons is much less clear, however. Biochemical analysis of the actions of NGF upon peripheral neurons has been hampered by the lack of a preparation of neuronal cells that are responsive to NGF but do not require it for survival. We report here that in adult dorsal root ganglion neurons, which can be isolated, enriched and maintained in culture in the absence of neuronal growth factors[2], the expression of mRNAs encoding the precursors of two neuropeptides, substance P and calcitonin gene-related peptide is regulated by NGF. Our results provide the first direct evidence of a continuous dynamic role for NGF in regulation of peptide neurotransmitter/neuromodulator levels in mature sensory neurons.

When adult dorsal root ganglion (DRG) neurons were grown in culture in the absence of NGF, the level of mRNA encoding the substance P precursor (preprotachykinin, PPT) declined progressively over 5 days (Figs 1, 2*a*). The substance P content of parallel cultures (Fig. 2*b*) declined by 60-70% over the same period. In cultures maintained in the presence of NGF (25 ng ml^{-1}), levels of PPT mRNA did not differ significantly from controls for the first 24 h, rose 1.5-4-fold (range in six experiments) over the next 24-48 h and did not change significantly thereafter. The abundance of PPT mRNA was 4-6-fold greater in cultures exposed to NGF for 48 h, compared with those deprived of NGF. After 5 days, PPT mRNA levels were 15-60-fold higher in NGF-treated cultures than in untreated cultures, as much because of a decline in PPT mRNA in NGF-deprived cultures as a continuing increase in PPT mRNA levels in response to NGF. Over the time course of these studies, the substance P content of NGF-treated cultures rose by approximately 50%.

Most, if not all, of the subpopulation of rat DRG neurons which exhibit substance P-like immunoreactivity also contain

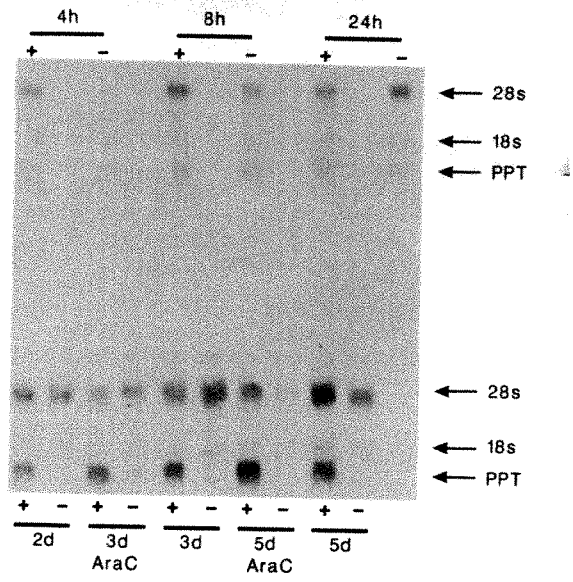

Fig. 1 Northern blot analysis of the effect of NGF upon the levels of PPT mRNA in adult rat DRG neurons. Replicate cultures of enriched adult DRG neurons (10,000 neurons per well) were established at $t = 0$. The mitotic inhibitor cytosine arabinoside (Ara C, 10^{-5} M) was present in replicates of the 3-day and 5-day cultures. At each time point, the neurons from four wells, grown in the presence or absence of NGF, were pooled, and total RNA was isolated. RNA samples were electrophoresed on formaldehyde-agarose gels and probed with a ^{32}P-labelled RNA probe complementary to human PPT mRNA. Under the washing conditions used (2 × SSPE/0.1% SDS at 65 °C), the autoradiographic signals due to the nonspecific binding of probe to 28S and 18S RNAs could be used to compare the amounts of RNA on each lane of the gel. Under more stringent conditions (0.1 × SSPE at 65 °C) the intensity of the signal due to PPT mRNA was undiminished, but the nonspecific binding of probe to RNA was abolished.
Methods. Cultures of adult rat DRG neurons were prepared as previously described[2]. Briefly, pooled DRG (40-48 per animal) from adult Sprague-Dawley rats (200-250 g) were cleaned of connective tissue and dissociated into a suspension of single cells by trituration after collagenase and trypsin treatment. After enrichment by separation of neurons from non-neuronal cells on the basis of their differential adhesion to a polyornithine substrate after overnight incubation, 10,000 neurons were plated out in each of the four wells (coated with polyornithine and laminin) of 35 mm-well tissue culture dishes (Greiner). The cells were maintained at 36.5 °C, in an atmosphere of 97% air: 3% CO_2 in F-14 culture medium (Imperial) supplemented with 10% horse serum (GIBCO-BRL), and, where indicated, cytosine arabinoside (10^{-5} M; Sigma). Highly purified 2.5 S mouse salivary gland NGF was added at 25 ng ml^{-1}. The medium was changed after 3 days where appropriate. For Northern analysis, RNA samples, each obtained from 40,000 neurons, were electrophoresed on 1.1% agarose gels containing formaldehyde, and transferred to nylon membranes (Biodyne A: Pall Ultrafine Filtration, Glen Cove, New York). A radiolabelled β-PPT cRNA probe was obtained by transcription, using [α-^{32}P]CTP and T7 RNA polymerase, of a fragment of human β-PPT cDNA (bases 174-417 of the published sequence[18] which had been subcloned into the Gem3 vector (Promega). The human cRNA probe was more than 95% homologous to the corresponding region of rat β-PPT mRNA[19].

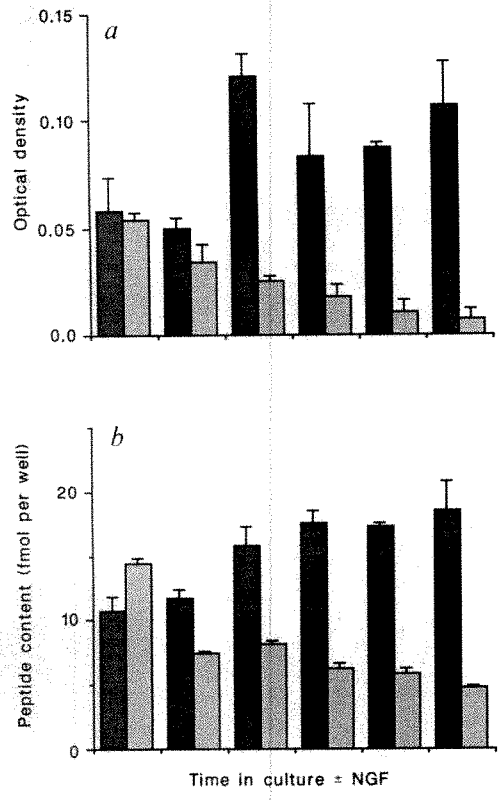

Fig. 2 Effect of NGF upon levels of (*a*) PPT mRNA and (*b*) substance P-like immunoreactivity in replicate cultures of adult rat DRG neurons maintained for the times shown in the presence (dark blocks) or absence (pale blocks) of NGF (25 ng ml^{-1}). **Methods.** *a*, Northern blots of total cellular RNA (derived from 40,000 neurons per sample) were hybridized with a PPT cRNA probe (see Fig. 1 legend) and results quantitated by densitometry using a Cambridge Instruments Quantimet 800 image analyser. *b*, The substance P-like immunoreactivity content of parallel cultures (5,000 neurons per sample) was determined by radioimmunoassay using a C-terminally directed, polyclonal substance P antiserum[20]. Values are mean ±s.e.m. ($n = 4$).

calcitonin gene-related peptide (CGRP)[3]. To establish whether the effects of NGF we described are specific for substance P or also affect the expression of other neuropeptides, we examined the levels of CGRP and its mRNA in the same or parallel cultures to those used above. As for substance P, the levels of CGRP mRNA declined (Fig. 3) in cultures deprived of NGF. CGRP mRNA levels were more than 15-fold higher in cultures treated with NGF for 5 days, than in similar cultures deprived of NGF. In parallel cultures in which CGRP content was measured by radioimmunoassay, a 4-fold increase in CGRP was detected over 4 days in culture in the presence of NGF (data not shown).

Although we have previously shown that the vast majority of adult rat DRG neurons survive in culture in the absence of NGF or other neurotrophic factors[2], we had to establish that the effects described above were not due to NGF promoting the survival of a small population of substance P-rich DRG neurons. Cultures were first deprived of NGF for 2 days (in total 3 days without NGF, including the enrichment procedure) and NGF was then added for 2 or 4 days, RNA was isolated, and PPT mRNA measured. Figure 4 shows that levels of PPT mRNA were elevated in NGF-treated cultures regardless of prior deprivation of NGF. We have shown previously that, even after NGF deprivation for 6 or more days, substance P levels in cultured adult DRG neurons can be elevated upon the addition of NGF[4]. We conclude, therefore, that the effect of NGF on PPT and CGRP mRNAs is not linked to survival but is due to a separate action of NGF on the function of adult sensory neurons.

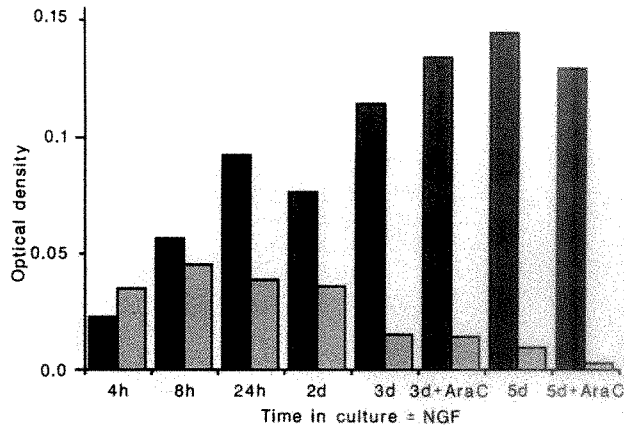

Fig. 3 Effect of NGF on the level of CGRP mRNA in duplicate cultures of adult rat DRG neurons mainained in the presence (dark blocks) or absence (pale blocks) of NGF (25 ng ml^{-1}) and, where shown, cytosine arabinoside (Ara C: 10^{-5} M). Northern blots of total cellular RNA (see Fig. 1 legend) were probed with a CGRP cRNA probe and the results quantitated by densitometry. The probe used was complementary to a 230-base pair sequence from 3′-untranslated region of human α-CGRP mRNA (ref. 21), ~76% homologous to the corresponding region of rat α-CGRP mRNA (ref. 22), and was generated using a commercial kit (Amersham).

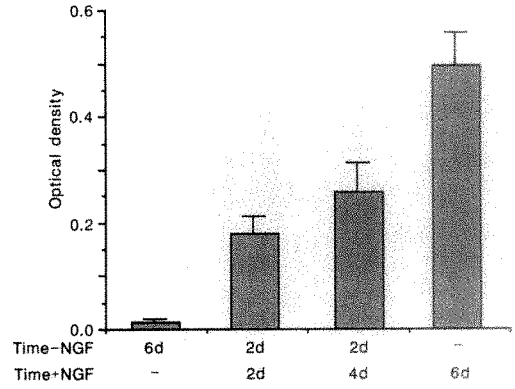

Fig. 4 Comparison of the relative levels of PPT RNA in replicate cultures of adult DRG neurons that were grown continuously in the presence of NGF, without NGF or in which the addition of NGF was delayed for 2 days after plating. Note that PPT mRNA levels were elevated (compared to controls) even after initial deprivation of NGF for 2 days. Values are mean ±s.e.m. ($n = 3$).

Although the procedures used to establish adult rat DRG neuronal cultures give an initial enrichment of >80% neurons, the proliferation of non-neuronal cells (Schwann cells and fibroblasts) cannot be suppressed without mitotic inhibitors such as cytosine arabinoside. To show that non-neuronal cells did not contribute directly or indirectly to the effects observed, several additional experiments were carried out. First, no PPT or CGRP mRNA was detectable in enriched cultures of non-neuronal cells grown in the presence or absence of NGF. Second, although cytosine arabinoside strongly inhibited the proliferation of non-neuronal cells in culture, this mitotic inhibitor did not influence the regulation of PPT and CGRP mRNA by NGF (Figs 1, 3).

There is now strong evidence that DRG neurons, once mature, do not depend on NGF for survival, as they do during development[5,6]. Instead, several lines of indirect evidence suggest that, in adult animals, NGF may be important in regulating the production of neuropeptides in sensory neurons. Various chemical, immunological and surgical interventions *in vivo* have been shown to lead to reductions in the levels of substance P

in adult DRG. For example, sciatic nerve section in the rat results in the loss of substance P from lumbar DRG, an effect attributed to NGF deprivation, as the substance P loss can be reversed by application of NGF to the cut stump of the transected nerve[7]. Given the considerable cell death in DRG after peripheral nerve section, it is possible[8] that the effects of exogenous NGF are related to protection against axotomy-induced cell death, rather than to direct stimulation of substance P biosynthesis. Further evidence that NGF may dynamically regulate the neuropeptide content of sensory neurons is provided by the observation that substance P levels are elevated in the target fields of sensory neurons after chemical (6-hydroxydopamine) or surgical destruction of NGF-dependent sympathetic neurons innervating the same structures; this elevation of substance P levels is probably due to an increased availability of target-derived NGF for the intact sensory neuron[9,10].

The observed differences in the levels of substance P or other peptides after NGF deprivation or administration *in vivo* are not evidence that NGF modulates the genes encoding the precursors of these peptides. Increased or decreased peptide levels could simply be a consequence of changes in the rates of translation, processing, release or degradation of the peptides themselves. The observed actions, the direct induction of the mRNAs, were not mediated indirectly through non-neuronal cells, nor were they linked to a survival-promoting effect of NGF. Our results suggest that a continuous supply of target-derived NGF is required as a retrograde effector to maintain the steady state levels of peptide neurotransmitters/neuromodulators found in mature sensory neurons. NGF treatment has been shown to evoke a number of rapid biochemical changes (including the phosphorylation of specific proteins[11–13] and the induction of certain genes[14–17]) in PC12 phaeochromocytoma cells. The system used here provides a means to establish the relevance of these observations to the mechanism of action of NGF in normal cells.

We thank Cheryl Lockett for performing the radioimmunoassays of substance P and CGRP.

Biosynthesis of the reverse transcriptase of hepatitis B viruses involves *de novo* translational initiation not ribosomal frameshifting

Retroviruses and many other types of genetic elements replicate by reverse transcription of RNA (for reviews, see refs 1 and 2). Although structurally and biologically very diverse, such elements carry conserved polymerase genes (*pol*) that encode proteins required for reverse transcription[3]. In most cases, the *pol* gene is preceded by an overlapping gene encoding one or more nucleocapsid proteins[4], in a different reading frame. Because both coding regions are represented in a single mRNA, the question arises of how the reverse transcriptase in the alternative reading frame is expressed. In retroviruses and retrotransposons it is expressed as a nucleocapsid-polymerase fusion protein by ribosomal frameshifting during translation of the overlapping region[5–8]. We have examined the mechanism of polymerase biosynthesis in another family of animal viruses that use reverse transcription, the hepatitis B viruses. Genetic and biochemical studies reveal that these viruses do not use ribosomal frameshifting to generate this enzyme, but instead direct translation initiation at an internal initiation (AUG) codon in the polymerase gene.

The hepatitis B viruses (HBVs) are small DNA viruses that produce persistent hepatic infections in a variety of animal hosts and replicate their DNA genomes via reverse transcription of an RNA intermediate[9]. All members of this family contain an open reading frame (ORF), "P" (for *pol*), which is homologous

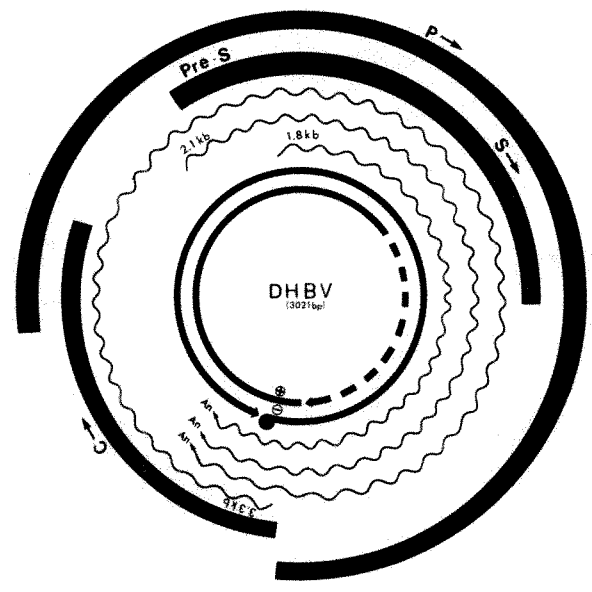

Fig. 1 Physical map of DHBV. Inner circles represent the DNA genome: the minus (−) strand (the strand synthesized through reverse transcription of viral RNA) is linked to a terminal protein[35] shown as a solid circle at its 5′ end; the plus strand is partially incomplete and shown by a dashed line at the 3′ end. The three wavy lines are the three main species of viral transcripts found in infected cells: the 2.1 kilobase (kb) mRNAs coding for the pre-surface (pre-S) antigens, the 1.8 kb mRNAs coding for the surface (S) antigens, and the 3.3 kb RNAs being the viral pregenome (the template for reverse transcriptase) and mRNAs coding for the core (C) antigens and viral polymerase (P). The three long open reading frames for *S*, *C* and *P* (*pol*) genes are drawn as filled boxes. Note that the 5′ end of the *P* gene is overlapped by the 3′ end of the *C* gene. For detail see ref. 36.

to retroviral *pol* genes. As Fig. 1 shows for the duck hepatitis B virus (DHBV)[10], the 5′ end of the P frame overlaps with the coding region (C) for the core (or nucleocapsid) protein; *pol* sequences are in the +1 frame relative to *core*. Figure 1 also shows the principal mRNAs identified in infected livers[11-14]. These include the subgenomic RNA species encoding the viral surface (S) proteins and the genome-length RNAs, one of which serves as the template for reverse transcription. As for other retroid elements, only the genome-length RNA contains the entire *pol* region. Such RNA is found in polyribosomes and is believed to be the mRNA for translation of both core and pol proteins. As no other (for example, spliced) viral RNAs have been reported in hepadnavirus infected cells, the main possibilities for polymerase biosynthesis are translational frameshifting to produce a core-pol polyprotein or translational initiation at an AUG in the *pol* gene. To date, no intact core-pol fusion proteins have been detected in productively infected cells (although truncated core-pol fusions were detected in some tumours in which viral DNA was probably rearranged[15]). However, pol-related proteins of relative molecular mass 70,000-90,000 (70-90K), without associated core determinants, have been identified in HBV virions[16,17]. It is unclear whether these polypeptides are the primary translation product of the *pol* gene or result from proteolytic cleavage of a large core-pol precursor.

To study pol biosynthesis we initially used a strategy which had been useful in the demonstration of translational frameshifting in retroviruses[5]. The *core-pol* overlap of ground squirrel hepatitis virus was cloned downstream of an SP6 bacteriophage promoter and *in vitro* transcripts were translated in extracts of rabbit reticulocytes, wheat germ, mouse liver and infected ground squirrel liver in attempts to identify a frameshift product. In all experiments, a detectable but low level (≤1%) of translational frameshifting occurred within the *core-pol* overlap (data not shown). Control experiments using the *pol-S* overlap (see Fig. 1) also exhibited this low level of frameshifting, suggesting that little or no specific frameshifting was occurring in the core-pol overlap region.

To assess the importance of the core-pol overlap *in vivo*, we constructed mutations in the *core* and *pol* genes designed to identify regions of the genome required for *pol* biosynthesis, using the DHBV genome. DHBV DNA can initiate infection of either intact animals (when delivered by intrahepatic inoculation[18-20]) or of cultured human hepatoma cell lines[21,22] (following transfection with cloned viral DNA[23,24]). For the assay in animals, one-day-old ducklings were intrahepatically injected with mutant DNA, and 18-21 days later (to allow for horizontal spread of progeny virus) viral replication was scored by Southern blot analysis of liver DNA. In the cell culture assay, 3-5 days post-transfection, viral core particles were purified by density centrifugation or immunoprecipitation[25], and DNA extracted from the cores was analysed by blot hybridization. Authentic DHBV replication generates a characteristic array of DNA forms, including open circular and linear duplexes and a heterogeneous array of linear single-stranded and partially duplex circular forms (see, for examples, Fig. 2*b*, lanes 2 and 4). Site-specific mutations were generated using synthetic oligonucleotides[26]. Whenever possible, changes in *pol* were made so as not to affect *core*.

In this strain of DHBV, the *core-pol* overlap is 305 nucleotides (nt) with two AUG codons in the *pol* frame; the A residue of the first AUG is designated position 1 (Fig. 2*a*). Note that the *pol* frame is open for 60 nt 5′ to its first AUG. We first constructed a frameshift mutant in a region near the 3′ end of the *core-pol* overlap (mutant 253, Fig. 2*a*) by deletion of a single nucleotide at that position, which places a termination codon in the *pol* frame 10 nt downstream of the mutation. None of the four ducks inoculated with 253 DNA became infected, and no viral DNA synthesis was observed after introduction of 253 DNA into cultured cells (Fig. 2*c*). This indicates that sequences upstream of this site are required for production of *pol* gene products.

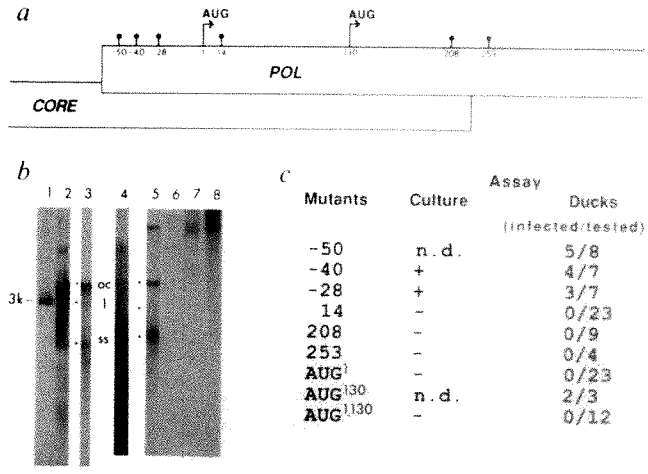

Fig. 2 Effects of mutations in the *pol* frame. *a*, Schematic representation of the *core* and *pol* overlap. Open boxes represents ORFs. In the overlap, the two AUG codons found in *pol* are marked by arrows. Individual nonsense mutations were made at the positions indicated by the closed circles (except mutant 253 which is a frameshift mutant). Each mutant contains sequence changes in both *core* and *pol* as follows: mutant 253, GCT (Ala) to GC in *pol*; mutant 208, CGA (Arg) to TGA (opal) in *pol* and TCG (Ser) to TTG (Leu) in *core*; mutant 14, TTG (Leu) to TAG (amber) in *pol* and ATT (Ile) to ATA (Ile) in *core*; mutant −28, TATca (Tyr) to TAAgc (ochre) in *pol*, and TCA (Ser) to AGC (Ser) in *core*; mutant −30, TGCgt (Cys) to TGAga (opal) in *pol* and CGT (Arg) to AGA (Arg) in *core*; mutant −40, TTTct (Phe) to TAAgt (ochre) in *pol* and TCT (Ser) to AGT (Ser) in *core*; mutant AUG1, AUG (Met) to ACG (Thr) in *pol* and GAT (Asp) to GAC (Asp) in *core*; mutant AUG130, AUG to ACG in *pol* and TAT (Tyr) to TAC (Tyr) in *core*. *b*, Southern blot of the replicative forms of viral DNA synthesized in duck livers or tissue culture following transfection. A DHBV probe was used to detect viral-specific sequences. Liver DNA samples from ducks tested with the wild-type DHBV DNA (lane 2) and the mutant −28 DNA (lane 3), and mutant −28 DNA from cytoplasmic cores extracted from transfected Huh7 cells (lane 4) are shown. DNA from cores prepared from HepG2 cells transfected with DNA of wild-type (lane 5), mutant 14 (lane 6), AUG1 mutant (lane 7) and AUG1,130 double mutant (lane 8) are also shown. Three major replicative forms of viral DNA are indicated by black dots; 'oc', open circular; 'l', linear; 'ss', single stranded. A linear 3 kbp DHBV DNA marker is shown in lane 1. *c*, Summary of DHBV mutants assayed both in tissue culture and in ducks. The results of duck inoculation experiments are shown to the right. '+' and '−', Positive and negative for pol function in HepG2 and/or Huh7 cells respectively. n.d., Not determined. The AUG1 and AUG1,130 mutants and mutant 14 all expressed a low level of pol activity detectable only after a long exposure of the autoradiograms; however, this activity does not support detectable viral replication in ducks.

To define further the boundaries of sequences required for *pol* expression, we analysed the behaviour of mutants with lesions in the *core-pol* overlap. To explore the 5′ boundary, several nonsense mutations were introduced in the *pol* ORF 5′ to its first AUG. Three of these, at positions −50, −40 and −28 relative to this AUG, do not affect the sequence of the *core* product, and all are viable in ducks and cultured cells (Fig. 2). Representative data for mutant −28 are shown in Fig. 2*b*, lanes 3 and 4. These data indicate that translation of pol must begin downstream of position −28. To map the 3′ boundary, nonsense mutations at positions 14 and 208 of pol were similarly analysed. As summarized in Fig. 2*c*, neither mutant grew in ducks and neither produced replicative intermediates in culture (see Fig. 2*b*, lane 6 for mutant 14). Therefore, sequences critical for *pol* expression are localized within a 42-nt region from −28 to +14 in the *core-pol* overlap. As this region contains an AUG codon, the contribution of this AUG to the generation of polymerase activity was addressed by further mutational studies.

If an internal initiation model is correct, the above results indicate that expression of the *pol* gene probably depends on the first of the two AUGs. When we changed the second AUG (AUG 130) to and ACG codon (without affecting *core*), two of three ducks tested positive for viral growth (Fig. 2*c*, mutant AUG^{130}), indicating that the second AUG is dispensable for *pol* function. However, when the first AUG of the *pol* ORF was mutated to an ACG codon (again without affecting *core*), the mutant did not replicate either in culture or in animals (Fig. 2*b*, lane 7, and Fig. 2*c*). Furthermore, a DHBV mutant with both of the AUG codons changed to ACG also failed to replicate in ducks (Fig. 2*c*, mutant $AUG^{1,130}$) or in culture (Fig. 2*b*, lane 8). These data suggest that the first AUG codon in the 42 bp region defined above is critical for viral *pol* expression or function. These results do not, however, exclude the possibility of ribosomal frameshifting within a small window from −28 to the first AUG, if this methionine was critical for *pol* function.

To define further the sequences in the *core-pol* overlap required for synthesis of pol protein, we constructed two amber mutants in the *pol* ORF at position −9 and −3 relative to the first AUG codon. When assayed, neither mutant replicated in ducks or in tissue culture (Fig. 3*a*). But as both contain a missense change in the *core* gene as well, the effects of the amber mutations on *pol* expression are ambiguous. A complementation assay was therefore developed to test the polymerase function independently of core function in tissue culture. A DHBV clone, DpA1, was constructed with multiple *pol* mutations, including the two AUG changes (at positions 1 and 130) described above and a 395-bp insertion downstream, yet maintaining the *core* amino-acid sequences intact (see Fig. 3*b*). This mutant expressed normal levels of viral mRNAs and core proteins (data not shown). As expected, the mutant is pol^-: when transfected alone into cells, DpA1 DNA produced no viral replicative intermediates (Fig. 3*c*, lane 2). The same result was observed for the −3 amber *pol* mutant (Fig. 3*c*, lane 3), but when this mutant DNA was cotransfected with DpA1, replicative forms of viral DNA were detected (Fig. 3*c*, lane 4). Similar results were obtained with the −9 amber mutant (data not shown).

It is very unlikely that DNA recombination can cause this result. No replicative forms were seen in control cotransfection experiments using two *pol* mutants, that is, DpA1 plus *pol*- mutant 253 or 208 (data not shown). In addition, to generate wild-type DNA from the −3 *pol* mutant and DpA1, recombination must occur within 2 bp (see Fig. 3*b*). To exclude DNA-DNA recombination further, however, we conducted an RNA-DNA cotransfection experiment. RNA containing only *core* sequences was synthesized *in vitro* using SP6 RNA polymerase and introduced into cells together with DNA carrying either the −9 or the −3 *pol* lesions. The products of viral polymerase activity were present in cell extracts collected 48 h post-transfection (Fig. 3*d*).

Finally, we investigated whether *pol* production is dependent upon translation of the antecedent *core* gene, a strong prediction of the frameshifting model. We constructed the plasmid Dfs1, which has a frameshift mutation in the *core* ORF, terminating *core* translation well upstream of the *core-pol* overrlap region (Fig. 4*a*). As expected, this mutant is not replication-competent in culture (Fig. 4*b*, left panel, lane 2). The ability of this mutant to generate a functional *pol* product was then tested using complementation assays. When this clone was cotransfected with DNA of the known pol^- mutant DpA1 (Fig. 3*b*), viral replication intermediates were produced (Fig. 4*b*, left panel, lane 1), indicating that Dfs1 does indeed produce pol proteins.

The possibility of DNA-DNA recombination was excluded by showing that the defect in Dfs1 could be complemented by the provision of the core function alone in an RNA-DNA cotransfection experiment. As shown in Fig. 4*b* (right panel, lane 1), when Dfs1 DNA was cotransfected with *core* mRNA, viral replicative intermediates were produced. As a control, cotransfection of Dfs1 with the SP6-core DNA template (which does not contain the DHBV promoter), did not allow the production of pol (the right panel, lane 2); thus any homologous recombination between incoming DNA molecules is not sufficient to allow detectable marker-rescue of the *core* frameshift mutation. These results indicate that *pol* expression does not depend on translation of *core*.

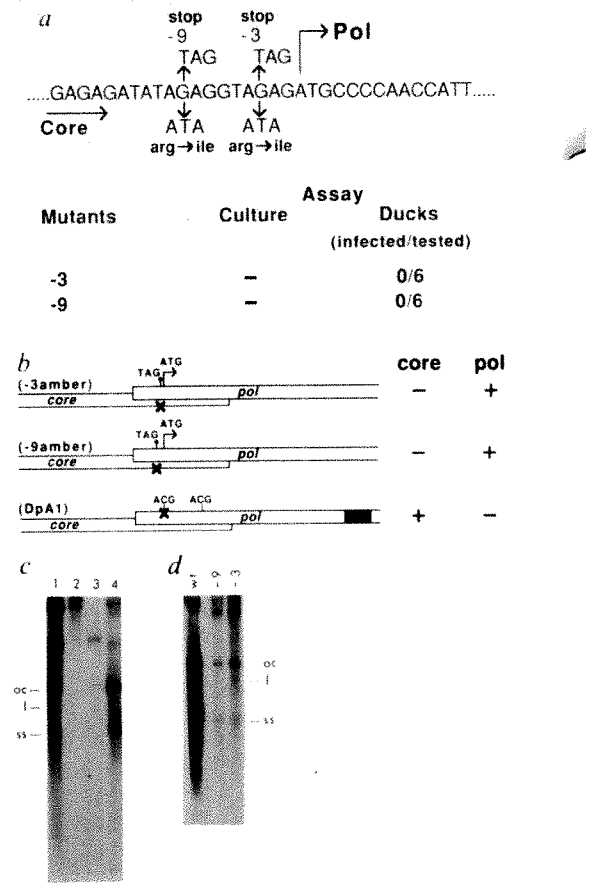

Fig. 3 Assay for *pol* function of two *pol* amber mutants immediately 5' to the first *pol* AUG. *a*, Assays in animals and cell culture. Point mutations were created individually at positions −3 and −9 in the *core-pol* overlap. As shown in the sequence both mutants create simultaneously a stop codon in the *pol* frame (arrow directed up) and a missense mutation in the *core* frame (arrow down). *b*, Schematic structure of the −3 and −9 *pol* amber mutants and the DpA1 clone. Both amber mutants bear a missense lesion in *core* (leading to a nonfunctional core protein) indicated by the '×'. The DpA1 bears two lesions in *pol* that affect the phenotype, one at the first AUG codon (the '×') and the other an insertion in the middle of *pol* (filled box). The second AUG to ACG mutation at +130 does not affect viral function (Fig. 2). The phenotypes determined by tissue culture assay are shown to the right. *c*, Complementation assay by DNA-DNA cotransfection. Lane 1, wild-type DNA alone; lane 2, DpA1 DNA alone; lane 3, the −3 amber mutant DNA alone; lane 4, DpA1 plus −3 amber mutant DNA. *d*, Complementation assay by RNA-DNA cotransfection. 'wt', Wild-type DNA alone; '−9', SP6 core RNA and −9 amber mutant DNA; '−3', SP6 core RNA and −3 amber mutant DNA.
Methods. For the construction of DpA1, a 395 bp fragment from *Staphylococcus aureus* protein A gene was cloned into the *pol* ORF at the *Kpn*I site (near the *S* gene AUG) using the $AUG^{1,130}$ mutant clone. DNA-DNA cotransfection was performed by the use of same amount of both DNAs (15 μg each in a 100-mm dish). The RNA-DNA cotransfection used poly-L-ornithine[37] at 20 μg ml^{-1} and only HepG2 cells were used for this assay.

We have presented several lines of evidence to indicate that the hepadnaviral reverse transcriptases are not made as core-pol fusion proteins by ribosomal frameshifting. Hepatitis B viruses thus differ from all well-studied retroviruses and retrotran

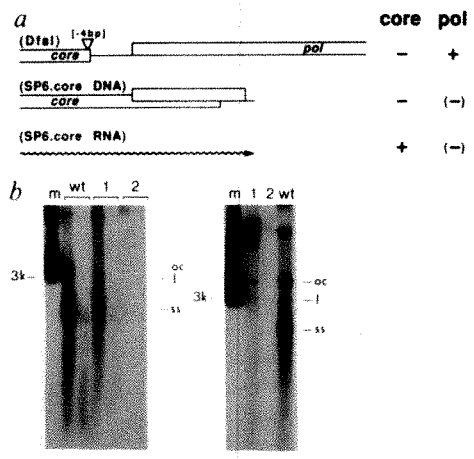

Fig. 4 Complementation assay with the *core* frameshift mutant Dfs1. *a*, Schematic structure of the Dfs1, SP6 core DNA and SP6 core RNA. In Dfs1, fill-in of the unique *Nsi*I site in *core* causes frameshift and premature termination (two codons downstream of the frameshift site) in the *core* frame. The SP6 core plasmid DNA was constructed in pSP65; it contains only part of the *pol* gene and has no eukaryotic promoter. The phenotypes of each construct as assayed in tissue culture are shown to the right. *b*, Complementation assay by DNA-DNA and RNA-DNA cotransfection. Cytoplasmic cores were prepared from transfected HepG2 cells by immunoprecipitation. In the left panel, lanes are shown in pairs; for each pair (wt, 1, and 2) the left lane shows DNA prepared from immunoprecipitated cores. The right lane shows the same core preparations extracted with phenol before proteolysis; loss of DNA from the aqueous phase indicates its association with a 5′ terminal protein[35]. Lanes 1, Dfs1 plus DpA1 DNA; lanes 2, Dfs1 DNA alone. In the right panel: lane 1, SP6 core RNA plus Dfs1 DNA; lane 2, SP6 core DNA plus Dfs1 DNA. m, The DHBV 3 kbp linear marker; wt, wild-type.

Methods. For the construction of Dfs1, the unique restriction site *Nsi*I (67 codons into the *core* gene) in the *core* gene of the genomic DHBV clone was filled in by bacteriophage T4 polymerase and recircularized with T4 ligase. For the construction of SP6 core clone, a DNA fragment containing the complete *core* gene from the *Acc*I site (in the pre-*C* region) to *Ava*I site (downstream of the *C* gene) was cloned into pSP65 under contaol of the SP6 promoter.

posons in that the reverse transcriptase function is not generated as a polyprotein with upstream nucleocapsid domains. A similar mechanism of pol generation has, however, been suggested for the cauliflower mosaic virus of plants[27], in which the *pol* gene can be separated from the upstream cistron without deleterious effects.

In all elements yet encountered that carry out reverse transcription, the reaction is confined to a particulate nucleoprotein structure that presumably serves to prevent the enzyme from gaining access to cellular mRNAs. In retroviruses, frameshifting also solves the problem of selective inclusion of the pol protein into viral particles, as the *gag* domain of the gag-pol fusion protein can interact with other gag proteins during assembly[28]. In the light of our results, it is clear that hepadnaviruses must solve this problem in some other way, for instance by protein-protein interactions between core and pol, or by direct interactions between the pol protein and pregenomic RNA.

Our data (and those of H. Schlicht, G. Radziwill and H. Schaller, personal communication) indicate that the HBV polymerase is synthesized by initiation at the first *pol* AUG, a view which is further corroborated by the conservation of this AUG in all members of the hepadnavirus family. Such initiations would probably occur from the internal position of the *pol* AUG in pregenomic RNA. Several models for this initiation can be envisioned: the most orthodox interpretation is as an extreme example of 'leaky' scanning[29], in which only the rare ribosomes that bypass the upstream AUGs during scanning from the 5′ cap become available to the *pol* AUG. The *pol* initiator, however, is itself in a suboptimal sequence context for initiation, with a C residue rather than a purine in the +4 position (see Fig. 3*a*). Also, in the 660 nt of the pregenomic RNA 5′ to this initiator, there are 15 other AUGs in all three reading frames (not including the *pre-core* AUG). These considerations argue against a simple extension of the leaky scanning model. In addition, experiments with the *core* frameshift mutant Dfs1 also rule out the possibility of ribosomes 'reaching back' for the *pol* AUG after terminating at the *core* terminator. Such 'backwards scanning' has been demonstrated in certain other bicistronic mRNAs with overlapping genes[30], but in Dfs1 *core* translation terminates 112 codons upstream of the *pol* AUG, and yet expression of *pol* is unaffected (Fig. 4).

We favour a model of *de novo* initiation at the *pol* AUG. One possibility is that the region flanking the *pol* initiator may have features that facilitate the direct entry of ribosomes or binding of translation initiation factors. Such sequences have been proposed for the cap-independent translation of poliovirus mRNA in which translation initiation occurs at an AUG downstream of an approximately 750-nt region containing seven other AUGs[31]. The use of the *pol* AUG, by whatever mechanism, seems to be low efficiency, as only minute quantities of polymerase protein have been detected in virions by direct biochemical and immunologic tests[16,17]. This may be of importance in viral gene regulation, as in retroviruses mutations which lead to overexpression of the *pol* precursor are highly deleterious to viral growth[32].

A growing number of examples exists of cellular messages which may use internal initiation. A recently described transcript of the human *c-abl* oncogene[33], for example, has a 5′ noncoding region of over 1 kb, with 13 AUGs; a similar situation exists upstream of an *Antennapedia* transcript in *Drosophila*[34]. It is reasonable to assume that these unusual coding organizations have potential regulatory significance. The further study of HBV *pol* and other eukaryotic genes displaying internal initiation should allow a better mechanistic understanding of this intriguing process.

We thank Dr J. Newbold for providing the anti-core antisera, J. Murphy for helping with the duck experiments, Dr J. Tuttleman for helpful advice and R. Colgrove for excellent computer assistance. Also, we thank Drs T. de Lange, D. Morgan and P. Bates for critical comments about the manuscript. This work was supported by grants from the NIH.

Soluble CD4 blocks the infectivity of diverse strains of HIV and SIV for T cells and monocytes but not for brain and muscle cells

Paul R. Clapham, Jonathan N. Weber, Denise Whitby, Kenneth McIntosh§, Angus G. Dalgleish*, Paul J. Maddon†, Keith C. Deen‡, Raymond W. Sweet‡ & Robin A. Weiss

The CD4 antigen has been subverted as a receptor by the human and simian immunodeficiency viruses (HIV-1, HIV-2 and SIV)[1–4]. Several groups[5–9] have reported that recombinant, soluble forms of the CD4 molecule (sCD4) block the infection of T lymphocytes by HIV-1, as CD4 binds the HIV envelope glycoprotein, gp120, with high affinity[10,11]. We now report that sCD4 blocks diverse strains of HIV-1, HIV-2 and SIV, but is less effective for HIV-2. The blocking effect is apparent even after adsorption of virions to CD4 cells. Soluble CD4 prevents HIV infection of T-lymphocytic and myelomonocytic cell lines, but neither sCD4 nor anti-CD4 antibodies inhibit infection of glioma and rhabdomyosarcoma cell lines.

We first investigated the capacity of sCD4 to block infection of diverse strains of HIV-1, HIV-2 and SIV. Table 1 shows that sCD4 preparations blocked the infectivity of each strain tested, but the HIV-2 isolates required 25-fold higher concentrations of sCD4 than HIV-1 to achieve comparable virus neutralization. In a separate experiment, virus strains were treated with sCD4 and titrated for surviving plaque-forming units (p.f.u.) on MT-4 cells[12] with the same results. Table 1 also shows that syncytium formation between HIV-producing and uninfected cells[1] was also inhibited, but was less sensitive to sCD4 than the neutralization of HIV or SIV virions was. This difference may result from the higher viral antigen 'load' present in the cell fusion reaction, which is also less sensitive to most neutralizing antibodies[13]. The relative sensitivity to sCD4 inhibition of the different virus strains was similar for syncytium formation and HIV titration.

The difference in sensitivity to sCD4 between HIV-1 and HIV-2 may reflect a high concentration of free gp120 in HIV-2 stocks, a higher density of gp120 on HIV-2 virions, or a higher binding affinity between HIV-1 gp120 and CD4. We used vesicular stomatitis virus (VSV) pseudotypes bearing the envelope glycoproteins of HIV to investigate whether free gp120 competed with sCD4 neutralization of virions. VSV(HIV) pseudotypes depend on CD4 surface receptors for binding to and entry into host cells[1]. Once inside the cell, however, the pseudotype replicates as VSV, providing a simple plaque assay for viral antigen-cell receptor interactions.

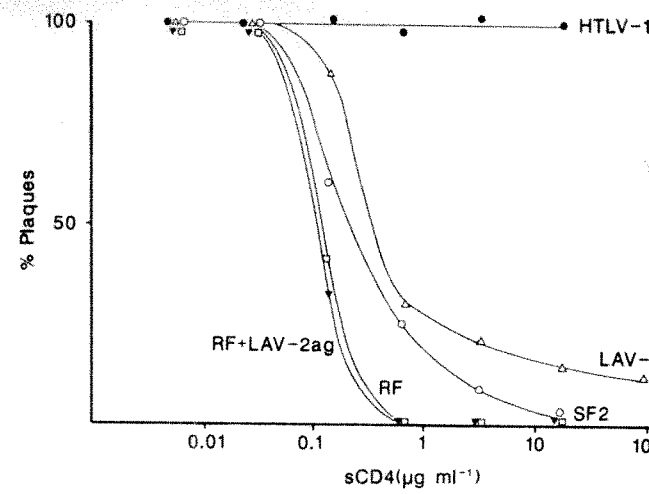

Fig. 1 Inhibition of VSV(HIV) plaque formation by sCD4. VSV pseudotypes bearing the envelope glycoproteins of HIV and HTLV-1 were prepared as described[1,19,35]. Pseudotype stocks were diluted to 10^3 p.f.u. ml^{-1} and were incubated for 1 h at 37 °C with sCD4 at the concentrations indicated. The reduction in plaque count was scored after assay on adherent CEM cells[1]. HTLV-1 was the PL strain[35], LAV-2_{ROD} represented HIV-2, HTLV-IIIRF (RF) and SF2 (ARV-2) represented HIV-1 strains. Undiluted LAV-2_{ROD} supernatant medium (LAV-2 ag) was added to VSV(RF) to test the effect of excess HIV-2 antigen on plaque inhibition by sCD4.

Figure 1 shows that sCD4 was effective in neutralizing both HIV-1 and HIV-2 pseudotypes. The pseudotype of the HIV-1 strain (HTLV-IIIRF) however was more sensitive to sCD4 than the HIV-2 strain tested (LAV-2), and a second HIV-1 strain (SF2, formerly known as ARV-2) was intermediate. SF-2 represents an isolate that is unusually sensitive to antibody neutralization by human sera[13], and it may react with sCD4 differently from other HIV-1 strains. The 80% blocking titres of sCD4 for VSV(HIV) pseudotypes were similar to those for HIV infectivity, being approximately 0.3 μg ml^{-1} for VSV(HTLV-IIIRF) and 5 μg ml^{-1} for VSV(LAV-2). As a control for the specificity of sCD4 neutralization, VSV(HTLV-1) pseudotypes were similarly reacted with sCD4 and were not inhibited at any concentration.

Evidence that the observed difference in sCD4 sensitivity between HIV-1 and HIV-2 is not related to soluble gp120 was obtained from a competition experiment in which supernatant medium from an LAV-2 releasing culture was added to VSV(HIV-1) before sCD4 treatment. The HIV-2 containing medium should have no effect on the VSV(HIV) plaque count, but should compete with VSV(HIV) particles for binding sCD4. LAV-2 supernatants were added to VSV(HTLV-IIIRF) at a concentration that required at least 40 μg ml^{-1} sCD4 for its infectivity to be inhibited. Despite this 'overload' of HIV-2 antigen, there was no reduction in sensitivity of VSV(HTLV-IIIRF) to sCD4 inhibition (Fig. 1). Addition of HIV-1 supernatant had no effect on VSV(HIV) inhibition either (data not shown).

We next investigated whether sCD4 would inhibit HIV after virions had bound to cellular CD4 receptors. Serial dilutions of HIV-1 were treated with sCD4 either before adsorption or one hour after adsorption to T cells. The results (Table 2) demonstrate the potential of sCD4 to block HIV post-adsorption, albeit some 50-fold less efficiently than if added to HIV before adsorption. The blocking effect indicates that even after binding to

Table 1 Soluble CD4 inhibition of infection and syncytium formation by HIV-1, HIV-2 and SIV strains

Virus		Inhibition titre of sCD4 ($\mu g\ ml^{-1}$)		
		Infection TCID	Plaque assay	Syncytium formation
HIV-1	HTLV-IIIB	0.3	0.3	1.5
	HTLV-IIIRF	0.3	0.3	1.5
	SF33	0.12	0.12	0.6
	CBL4	0.3	ND	1.5
HIV-2	LAV-2_{ROD}	7.6	7.6	38
	CBL20	7.6	7.6	38
SIV	SMM (mangabey)	0.6	ND	7.6
	MAC (macaque)	0.6	ND	7.6
	AGM (green monkey)	0.6	ND	7.6

Soluble CD4 representing the whole of the extracellular domain was prepared as previously described[8]. For infection inhibition (neutralization) assays, serial dilutions of sCD4 were incubated at 37 °C for one hour with 1,000 T-cell infectious doses (TCID) of HIV or SIV. The surviving infectious virus was titrated by plating dilutions of the sCD4-treated virus on C8166 T cells and recording virus replication by the appearance of syncytia and reverse transcriptase activity 48–72 hours later[19]. Virus treated with sCD4 was also titrated in the MT4 cell HIV plaque assay[12]. For syncytium formation, chronically infected H9 cells were mixed with uninfected C8166 indicator cells and multinucleated syncytia were counted after incubation overnight[19]. The concentration of sCD4 neutralizing over 80% of TCID and p.f.u., and causing 80% inhibition of syncytium formation are tabulated for each virus strain. ND, not determined.

Table 2 Reduction of HIV-1 infection by sCD4 after adsorption of virus to T-lymphocytes scored by syncytial focus assay

Virus dilution	No. sCD4	sCD4 added before HIV adsorption	sCD4 added after HIV adsorption
10^{0}	con, con	1, 2	105, 85
10^{-1}	203, 240	0, 0	10, 13
10^{-2}	25, 41	0, 0	3, 1
10^{-3}	4, 2	0, 0	0, 0

HIV-1 (HTLV-IIIRF) was titrated by a syncytial focus assay as follows: C8166 cells (10^6 cells in 0.5 ml RPMI/1640 medium with 10% fetal calf serum) were plated into 12-mm tissue culture wells in 24-well plate wells (Nunclon, Denmark) coated with 50 $\mu g\ ml^{-1}$ poly-L-lysine to form a monolayer. After 20 min at room temperature, appropriate virus dilutions were added and adsorbed for 1 h on ice. The monolayers were washed in culture medium to remove unabsorbed virus and were incubated in medium for 1 h, washed again, and overlaid with 1 ml culture medium containing 0.9% molten Sea Plaque agarose (FMC Bioproducts). After 42 h incubation at 37 °C, 1 ml agarose containing 0.0032% Neutral Red was added and at 48 h discrete focal areas of syncytia were counted by low power magnification (×20). The linear dose-response of syncytial foci in the absence of sCD4 indicated that each focus resulted from a single infectious unit of HIV and the focus titre correlated well with HIV titration by end-point dilution on C8166 cells in suspension ($TCID_{50}$). To measure the inhibitory effect of sCD4, 40 $\mu g\ ml^{-1}$ protein was added to serially diluted HIV for 1 h on ice in culture medium before adsorption, or was added to the washed cell monolayer on ice following virus adsorption. The numbers represent focus counts of duplicate wells for each sCD4 treatment and virus dilution. Con, confluent syncytia.

cellular CD4, HIV infection can be inhibited by the competing soluble homologue, before internalization by a *p*H-independent fusion process[14–16].

HIV infection of T-lymphocytic[1,2,17] and monocytic[18,19] cells can be blocked by preincubating the cells with certain anti-CD4 monoclonal and polyclonal antibodies. Other cell types, notably glioma cell lines[20–22] and RD cells[23], can also be infected with high titres of HIV-1. HIV-susceptible glial cell lines, such as U138, are negative for CD4 surface expression by immunofluorescence, but express low levels of CD4 mRNA. (J.N.W., unpublished observations). Preliminary experiments indicated that anti-CD4 antibodies did not inhibit HIV infection. The low density of CD4 expression on glial cells might prevent anti-CD4 attaching with sufficient avidity to compete with HIV binding. By using sCD4 as an inhibitory reagent binding to the virion glycoproteins, gp120, rather than to the cellular receptor molecule, the question of whether CD4 is required for infection of these cells can be addressed more clearly.

Table 3 shows that U138 astroglioma cells, but not U87 astroglioma cells, can be infected with the HTLV-IIIRF strain of HIV-1. The TE671 cell line can also be infected with HIV[20]. This line was thought to be derived from a human medulloblastoma[24], but is now known to be the RD rhabdomyosarcoma cell line[25]. A relatively high input of virus required for U138 and RD cell infection ($>10^3$ T-lymphocyte infectious units), and the infection is only weakly productive. Not enough virions are released into the supernatant medium of infected U138 or RD cultures to register as positive in reverse transcriptase or p24 antigen assays, and it seems that only a small proportion of cells contain HIV antigens or proviral DNA[20–22]. Virus can readily be rescued by cocultivation with a fully permissive T-cell line however, such as C8166 or by transfer of the supernatant medium of infected glioma cell cultures to C8166 cells. Incubation of HIV-1 with sCD4 before plating failed to block infection of brain or muscle cell lines at 18 $\mu g\ ml^{-1}$ or even 180 $\mu g\ ml^{-1}$. In a parallel experiment, monoclonal antibodies reacting to CD4 antigen (Leu3a, F101-5) efficiently blocked HIV infection of $CD4^+$ lymphocytic and monocytic cells but also failed to block infection of brain tumour cells. In contrast, a human serum containing antibodies to gp120, gp41 and gag antigens neutralized HIV for all cell types (Table 3). It is most unlikely that input virus has been carried over in the brain cell cultures, in view of the serial passage and trypsinization of these cells, and that the resistant U87 glial cell line did not yield rescued virus upon subsequent cocultivation with T cells (Table 3). Moreover, proviral DNA has been detected after HIV infection of these cell types[20,21]. We therefore conclude that HIV infects glial and muscle cells in a way that is not mediated by CD4.

Soluble CD4 is under investigation as a therapeutic agent in HIV-infected subjects. One concern is that sCD4 might itself be immunosuppressive, reacting *in vivo* with the apparent natural ligand for CD4, the major histocompatibility complex (MHC) class II antigens[4,26]. Little or no effect of sCD4 on class II-restricted T-cell interactions is seen *in vitro* however[7]. The primary recognition site on CD4 for gp120 is close to the Leu3a antigenic epitope[4,27] and has been mapped to the N-terminal immunoglobulin V-like domain[28,29]. An sCD4 fragment or peptide containing this site but which was not involved in immune recognition would be desirable, though the evolutionary conservation among primate species of the gp120/Leu3a site suggests that this epitope may be important for normal functions of the CD4 molecule[30].

Our results show that neither sCD4 nor Leu3a antibody block infection of certain brain and muscle cell lines. These unexpected results indicate that HIV may not require cell surface CD4, nor perhaps viral gp120, to gain entry to these cells *in vitro*. It would seem unlikely to depend on an artefactual 'transfection' as described for bacteriophage[31] as DEAE-dextran was not used to enhance virion uptake, and the RD/TE671 cultures became infected with an input as low as 0.05 T-cell infectious doses per cell (Table 3). HIV and VSV(HIV) pseudotypes are unable to infect mouse cells expressing human CD4 or to induce cell fusion although the virions bind to the CD4 molecules[32]. A second membrane molecule may therefore be required for fusion and viral penetration. In view of the relatively low efficiency of infection of glioma and myoblast cells compared to $CD4^+$ T

Table 3 Effect of sCD4 and anti-CD4 antibody on HIV-1 infection of different human cell types

Cell type	Input HIV (TCID)	Human anti-HIV-1 SF	Human anti-HIV-1 RF	Leu3a anti-CD4 SF	Leu3a anti-CD4 RT	sCD4 180 μg ml^{-1} SF	sCD4 180 μg ml^{-1} RT	Control SF	Control RT
T cell									
C8166	5×10^3	−	−	−	−	−	−	+ + +	20,000
Myelomonocyte									
U937	5×10^5	ND	ND	−	−	−	−	+ + +	27,000
	5×10^3	−	−	−	−	−	−	+ + +	55,000
HL60	5×10^5	ND	ND	−	−	−	−	+ +	49,000
	5×10^3	−	−	−	−	−	−	+ +	9,000
Glioma									
U138	5×10^5	−	−	+ +	21,000	+ +	23,000	+ +	23,000
U87	5×10^5	−	−	−	−	−	−	−	−
Muscle									
RD/TE671	5×10^5	−	−	+ +	18,000	+ +	26,000	+ +	19,000
	5×10^3	−	−	+ +	9,000	+ +	20,000	+ +	18,000

HIV-1 (HTLV-IIIRF strain) was incubated with anti-HIV-1 antibody or with sCD4 for 1 h at 37 °C before plating on 10^6 cells of the types indicated. Syncytium formation (SF) and reverse transcriptase (RT) activity in the medium was scored 5 days post-infection for the T-cell and myelomonocyte cultures. For the glial and myoblast cultures there were no detectable SF or RT activity as previously described[20–23]. After seven days and two trypsin-mediated passages of the glial and myoblast cells, C8166 cells were added to the cultures, and SF and RT activity was scored 3 days later. Virus production for cells exposed to HIV-1 (not treated with anti-CD4 or sCD4) was also detected after 3 weeks and 6 passages in U138 and RD/TE671 cells, but not U87 cells. The glial cells expressed glial fibrillar acidic protein, confirming their provenance. SF scores: +++, >50% giant syncytial cells in culture; ++, 10–50% syncytial cells; +, 1–9% syncytial cells; −, no discernable syncytia. RT scores in c.p.m. acid precipitable [^{3}H]thymidine incorporation; −, <1,000 c.p.m. ND, not determined.

lymphocytes, HIV infection might occur by gp41-mediated membrane fusion in the absence of specific gp120-CD4 receptor interaction.

It is not clear whether HIV infection of astroglial cells has a role in HIV encephalopathy (as infection is mainly detectable in microglial and endothelial cells[33,34]) or whether muscle infection is related to the weight loss and wasting seen in AIDS. Although our results may be restricted to cells *in vitro*, HIV infection of glial and muscle in the presence of excess sCD4 merits further investigation, given the interest in developing sCD4 as a therapeutic agent.

We thank M. Popovic and R. C. Gallo for providing C8166 cells, HTLV-IIIB and HTLV-IIIRF, J. Levy for SF2 and SF33, L. Montagnier for LAV-2, P. Marx for SIV_{SMM}, M. Daniel for SIV_{MAC}, M. Hayami for SIV_{AGM}, K. Nilsson for U87, U138 and U937 cells, M. Stratton for TE671 cells, and J. Zavada for sheep hyperimmune serum against VSV. This study was supported by the MRC, Wellcome Trust and Cancer Research Campaign.

Productive dual infection of human CD4$^+$ T lymphocytes by HIV-1 and HHV-6

Paolo Lusso, Barbara Ensoli, Phillip D. Markham*, Dharam V. Ablashi, S. Zaki Salahuddin, Erwin Tschachler, Flossie Wong-Staal & Robert C. Gallo

Laboratory of Tumor Cell Biology, National Cancer Institute, Bethesda, Maryland 20892, USA

Although infection by HIV-1 (refs 1 and 2) has been implicated as the primary cause of AIDS and related disorders[3,4], cofactorial mechanisms may be involved in the pathogenesis of the disease. For example, several viruses commonly detected in AIDS patients and capable of transactivating the long terminal repeat of HIV-1, such as herpesviruses[5–7], papovaviruses[7], adenoviruses[8] and HTLV-I (ref. 9), have been suggested as potential cofactors. Another candidate is human herpesvirus-6 (HHV-6, originally designated human B-lymphotropic virus)[10–12], which has not only been identified in most patients with AIDS by virus isolation[10,13,14], DNA amplification techniques[15] and serological analysis[16], but is also predominantly tropic and cytopathic *in vitro* for CD4$^+$ T lymphocytes[17,18]. Here we demonstrate that HHV-6 and HIV-1 can productively co-infect individual human CD4$^+$ T lymphocytes, resulting in accelerated HIV-1 expression and cellular death. We also present evidence that HHV-6 transactivates the HIV-1 long terminal repeat (LTR). These observations indicate that HHV-6 might contribute directly or indirectly to the depletion of CD4$^+$ T cells in AIDS.

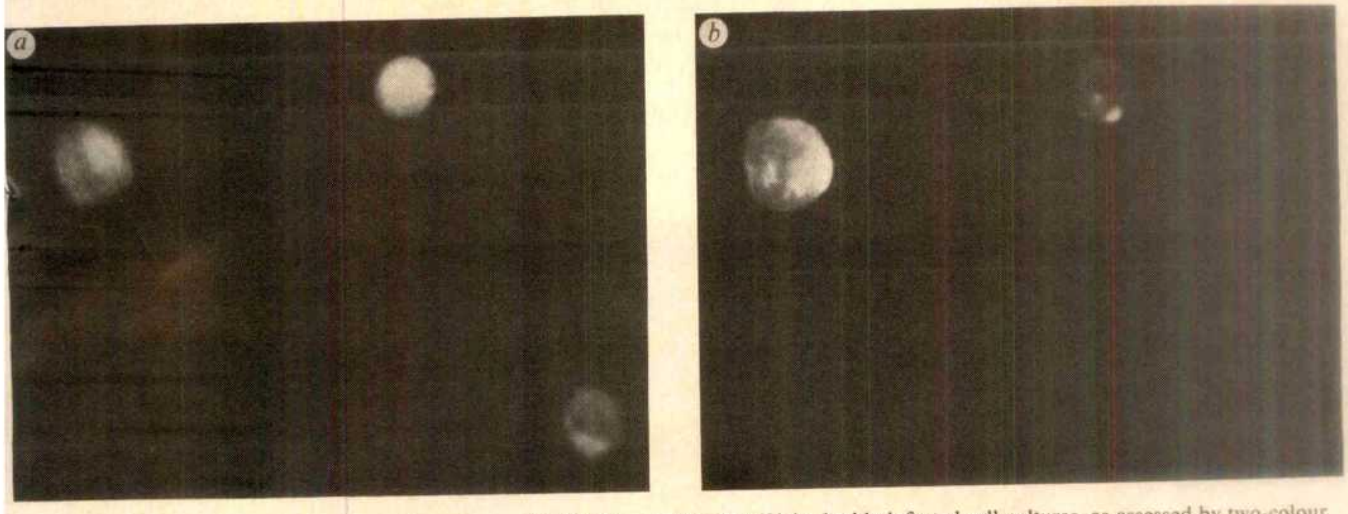

Fig. 1 Simultaneous expression of specific antigens of HHV-6 (*a*) and HIV-1 (*b*) in doubly infected cell cultures, as assessed by two-colour indirect immunofluorescence.

Methods. PBMC from healthy volunteers were isolated by Ficoll-Hypaque gradient centrifugation and cultured at 37 °C in a humidified atmosphere of 5% CO_2 at a density of 1×10^6 ml^{-1} in RPMI medium supplemented with 15% fetal bovine serum, 1 μg ml^{-1} phytohaemagglutinin-P and 5 μg ml^{-1} polybrene. Cells were washed with RPMI after 24 h, counted and exposed for one hour at 37 °C to HIV-1 alone (isolate HTLV-III$_B$), HHV-6 alone or to HIV-1 plus HHV-6; each virus was at an infectious multiplicity of ~0.3. Infected cells were then cultured at 10^6 per ml in RPMI supplemented with 10% fetal bovine serum and 20% of their original culture medium collected before infection. The absolute numbers of viable cells, CD4$^+$ cells and giant multinucleated cells (syncytia) were recorded at 2-day intervals. After removal of dead elements by Ficoll-Hypaque gradient centrifugation, viral antigen expression was evaluated in parallel by indirect immunofluoresence on cytocentrifuge preparations fixed for 5 min in cold acetone[18]. A murine monoclonal antibody against the gag p24 protein of HIV-1 (M26)[20] was used at 2 μg ml^{-1}; an anti-HHV-6 human serum (N828), extensively adsorbed with uninfected phytohaemagglutinin-activated PBMC, was used at a final dilution of 1:15. Phycoerythrin-conjugated (red) goat anti-mouse IgG and fluorescein-isothiocyanate-conjugated (green) goat-anti-human IgG polyclonal antisera (both specific for γ-chain; Kirkegaard and Perry Inc., Maryland), were used as second layer antibodies. Samples were visualized with a Leitz Ortholux II fluorescence microscope equipped with a ×40 dry objective. Two-colour immunofluorescence also demonstrated that cells infected with HHV-6 and HIV-1 displayed a CD4$^+$ T-cell phenotype.

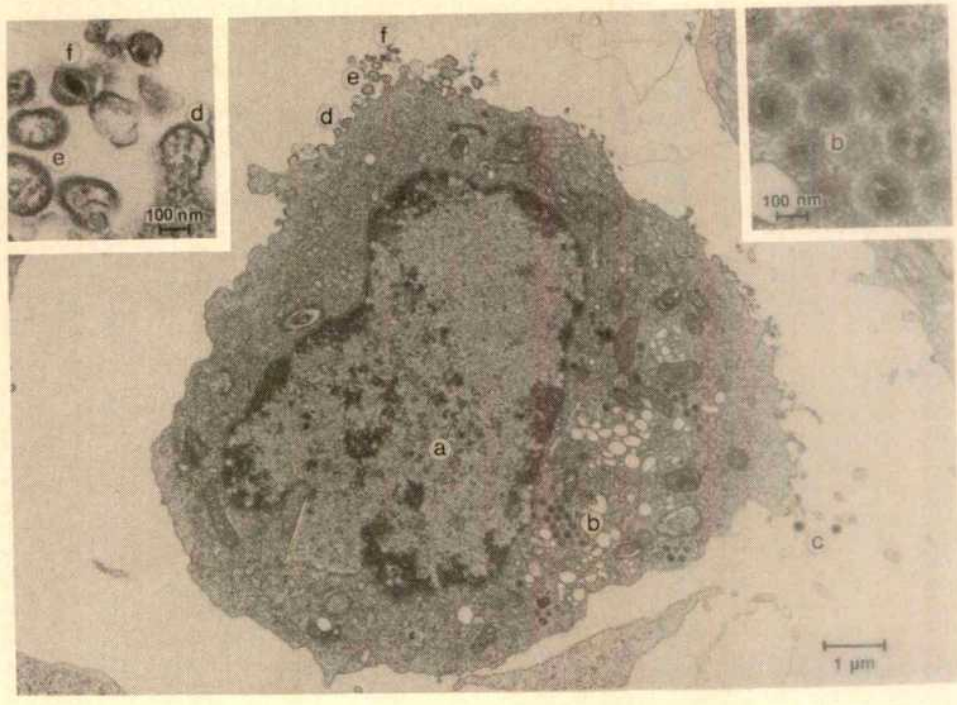

Fig. 2 Electron micrograph of a cell with the morphological features of an activated lymphocyte, eight days after simultaneous infection of PBMC cultures with HIV-1 and HHV-6. *a*, Unenveloped intranuclear HHV-6; *b*, unenveloped intracytoplasmic HHV-6; *c*, mature extracellular HHV-6; *d*, budding HIV-1 particles; *e*, immature extracellular HIV-1 (rarefied core); *f*, mature HIV-1 (dense core). Magnification is ×15,000 (detailed inserts, ×75,000). Cells were extensively washed with cold PBS, centrifuged at 1,500 r.p.m. and fixed with 1.25% glutaraldehyde, 0.1 M sodium cacodylate, 0.5×PBS for electron microscopy.

Freshly isolated normal human peripheral blood mononuclear cells (PBMC) were activated *in vitro* with purified phytohaemagglutinin and subsequently co-infected with HIV-1 and HHV-6. Two-colour indirect immunofluorescence was used to detect specific viral antigens and demonstrated that individual cells could serve as a simultaneous target for both viruses (Fig. 1). Electron microscopy illustrated the productive nature of this dual infection, showing the complete pathway of HHV-6 and HIV-1 maturation within individual lymphocytes. HHV-6 was visible as both immature (namely, nuclear or cytoplasmic unenveloped nucleocapsids) and mature extracellular particles (Fig. 2*a*–*c*). Budding, extracellular immature and mature HIV-1 virions could be recognized if associated with the same cell (Fig. 2*d*–*f*).

The expression of viral messenger RNA, as analysed by northern blotting, was qualitatively unaltered in dually infected cultures and the viruses released were found to be infectious for normal human PBMC (data not shown). As summarized in Table 1, however, HIV-1 antigen expression was consistently accelerated in the course of co-infection with HHV-6. It must

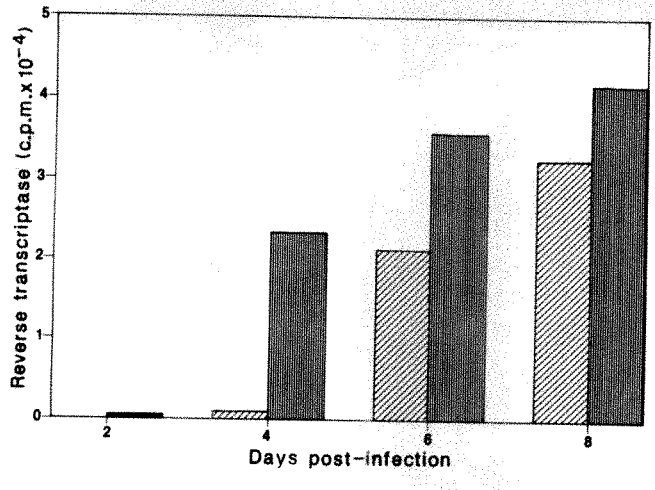

Fig. 3 Reverse transcriptase activity in cultures of PBMC infected with HIV-1 alone (cross-hatched) or with HIV-1 and HHV-6 together (shaded). Details of infection and culture procedures are given in the legend to Fig. 1. Polyethyleneglycol-precipitated cell culture supernatant fluids were assayed for reverse transcriptase activity as previously described[2].

be emphasized that the majority of HIV-1-positive cells were simultaneously expressing HHV-6 antigens. Moreover, these immunofluorescence determinations probably underestimated the actual magnitude of the infection, as dead (presumably infected) cells were removed before testing. An accelerated expression of HIV-1 in dually infected cultures was further indicated by the earlier detection of reverse transcriptase activity (Fig. 3).

Consistent with the acceleration of HIV-1 expression, we also observed a more rapid induction of cytopathicity in the course of dual infection. The loss of $CD4^+$ T lymphocytes was significantly accelerated in dually infected PBMC cultures (Fig. 4*a*) and mathematical analysis of the data suggested a synergistic cytocidal action of HIV-1 and HHV-6 (Fig. 4*b*). A parallel decline of total cell viability was also observed in these cultures. For example, eight days after infection, the absolute numbers of viable cells were $4.3 \pm 0.5 \times 10^5$ with HIV-1 and $2.7 \pm 0.5 \times 10^5$ with HHV-6, as compared to $0.6 \pm 0.2 \times 10^5$ with both viruses together ($P < 0.01$). These observations indicate that, despite the documented down-regulation of CD4 molecules by HIV-1 gp120/160 glycoproteins[19], the chief mechanism for $CD4^+$ cell depletion in our cultures was a virus-induced cytopathic effect. Moreover, HIV-1 induced syncytia were identified earlier in doubly infected cultures (Table 1). Dual infection of $CD4^+$ T cells was also observed using established human $CD4^+$ T cell lines (not shown).

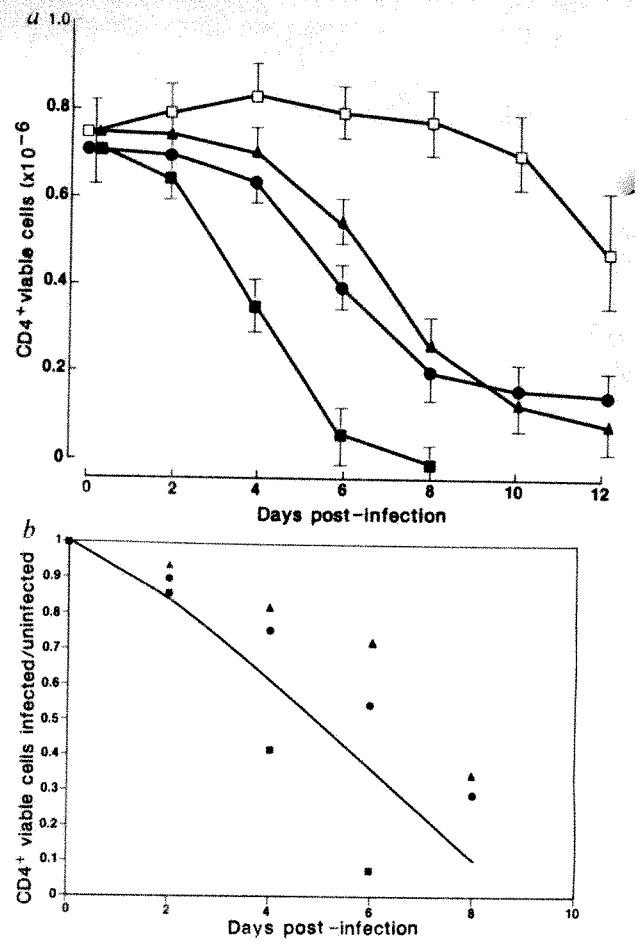

Fig. 4 Cytopathic effect in the course of co-infection of normal human PBMC by HIV-1 and HHV-6. Open square, uninfected; filled triangle, HIV-1 alone; filled circle, HHV-6 alone; filled square, HIV-1 plus HHV-6. *a*, Kinetics of $CD4^+$ cell viability in singly and doubly infected cultures. Data represent the averaged results (± standard deviation) from 3 separate experiments. *b*, Synergystic effect of HIV-1 and HHV-6 in inducing cytopathicity on normal PBMC cultures. All values are normalized with respect to uninfected control cultures (representing the ratio between viable $CD4^+$ cell counts in infected cultures and viable $CD4^+$ cell counts in uninfected cultures for each time point). The solid line represents the predicted curve in the course of an additive effect and was calculated according to the following formula: $N_t = p_t q_t$ (where p_t and q_t correspond to normalized $CD4^+$ cell counts at time t in cultures infected with HIV-1 and HHV-6 respectively). By day 4 or 6 post-infection, the observed mortality in dually infected cell cultures was 2–3 times greater than the values predicted for a simple additive effect.

* Phytohaemagglutinin-activated PBMC were infected with HIV-1, HHV-6 or both viruses simultaneously. Details of the infection procedure and indirect immunofluorescence assay are given in the legend to Fig. 1.

† Per cent immunofluorescent-positive viable cells and in parenthesis absolute numbers of positive viable cells $\times 10^{-4}$ (averaged results from three separate experiments) for the indicated virus, determined as described in the legend to Fig. 1.

‡ Presence (+) or absence (–) of syncytia (S) as evaluated on Wright–Giemsa stained cytocentrifuge preparations, each containing 2×10^5 cells.

‖ NA, not applicable. In these cultures no viable cells were detected by day 10 post-infection.

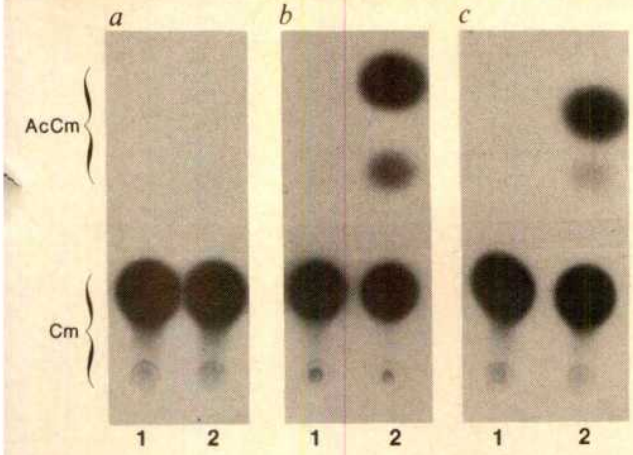

Fig. 5 Transactivation of the choramphenicol acetyltransferase (*CAT*) gene linked to the HIV-1 LTR when transfected into MOLT-3 cells which were uninfected (*a*), infected with HIV-1 (*b*) or infected with HHV-6 (*c*). Plasmids were pC15CAT (lanes 1; ref. 21) containing the HIV-1 LTR linked to the bacterial *CAT* reporter gene, and the control pSVOCAT (lanes 2; ref. 22) that lacked promoter-enhancer sequences.

Methods. 10^7 cells were transfected with 10 μg plasmid DNA by the DEAE-dextran technique[23], collected after 40 h and processed to obtain 100 μl cellular extract; aliquots of 20 μl were subsequently used for CAT assays in a 3-h incubation[24]. Different percentages of cell viability were found in the various cultures at the time of collection: *a*1, 79%; *a*2, 89%; *b*1, 51%; *b*2, 49%; *c*1, 26% and *c*2, 29%. The acetylation of chloramphenicol (%) as estimated from liquid scintillation counting was *a*1, 0.19; *a*2, 0.24; *b*1, 2.5; *b*2, 30; *c*1, 0.27 and *c*2, 19.7. Cm, chloramphenicol; AcCm, acetylated chloramphenicol.

The accelerated virus expression and cytopathicity in dually infected cultures suggested that a direct interaction occurs between HIV-1 and HHV-6. We therefore studied the transactivation of the HIV-1 LTR by HHV-6 using the human $CD4^+$ T-cell line MOLT-3. As illustrated in Fig. 5, there was a consistent transactivation in HHV-6-infected cells which was not found in uninfected cells. We obtained similar results using the $CD4^+$ T-cell line CEM (data not shown).

The part played by cofactorial mechanisms in the pathogenesis of AIDS and in particular the relevance of other potentially immunosuppressive agents are still to be clarified. We have previously demonstrated that HHV-6 exerts a direct lytic effect on human $CD4^+$ T lymphocytes[18]. Here we have shown that HHV-6 can co-infect individual T cells with HIV-1 and can transactivate the expression of HIV-1. The simultaneous presence of both viruses in the same cell emphasizes the potential importance of this transactivation. Replication of HHV-6 might in turn be enhanced by co-infection with HIV-1, thus generating a vicious cycle. Our observations, although they do not prove the aetiological involvement of HHV-6, are consistent with a possible cofactorial role of this virus in one of the critical pathological features of AIDS, namely the $CD4^+$ T-cell depletion. Prospective long-term seroepidemiological and *in vivo* investigations, using animal models or two-probe hybridization to detect dual infection in individual patient cells, will help evaluate the contribution of potential cofactors to the course of HIV-1 infection.

We thank Dr M. Gonda and K. Nagashima for electron microscope analysis, Dr F. Veronese for M26, Professor M. DiMarzo for statistical analysis and S. DeRocco for technical assistance.

Genetically haploid spermatids are phenotypically diploid

Robert E. Braun, Richard R. Behringer*, Jacques J. Peschon, Ralph L. Brinster* & Richard D. Palmiter

Because chromosomal homologues segregate from one another during meiosis, spermatids are genetically different. Post-meiotic gene expression could lead to gametic differences, some of which might lead to preferential transmission of certain alleles over others. In both insects and mammals, however, all the cells derived from a single spermatogonial cell develop within a common syncytium formed as a result of incomplete cytokinesis at each of the mitotic and meiotic cell divisions[1–3]. It has been proposed that the intercellular bridges connecting the cells, which are about 1 μm in diameter[4], permit the sharing of cytoplasmic constituents, thus ensuring the synchronous development of a clone of cells and gametic equivalence between haploid spermatids[2,5,6]. By analysing the product of a transgene which is expressed exclusively in post-meiotic germ cells in hemizygous transgenic mice, we have shown that genetically distinct spermatids share the product of the transgene and hence can be phenotypically equivalent.

The experiments described here were designed to determine whether either RNA or protein can pass through the intercellular bridges which connect spermatids. To address these questions we have generated transgenic mice that carry a chimaeric gene consisting of the mouse protamine 1 (*mP1*) transcriptional regulatory sequences, fused to the human growth hormone (*hGH*) structural gene. The advantage of using transgenic mice for such an analysis is that mice can be generated which are hemizygous for the transgene, that is, the introduced DNA is present on only one of the two chromosomal homologues, so that after meiosis only half of the spermatids carry the transgene (Fig. 1*a*). The *mP1* gene is transcribed exclusively during spermiogenesis, the haploid phase of spermatogenesis[7]. Previous studies have shown that 4.8 kilobase (kb) of 5′ sequence is sufficient for the proper tissue-specific and temporal regulation of *mP1* in transgenic mice[8]. The construct used in this study contains 4.1 kb of *mP1* 5′ sequence fused to the *hGH* gene (Fig. 1*b*).

Two independent lines of transgenic mice harbouring the *mP1-hGH* gene were established (Fig. 1*b*). To determine the transmission frequency of the transgene, tail DNA from

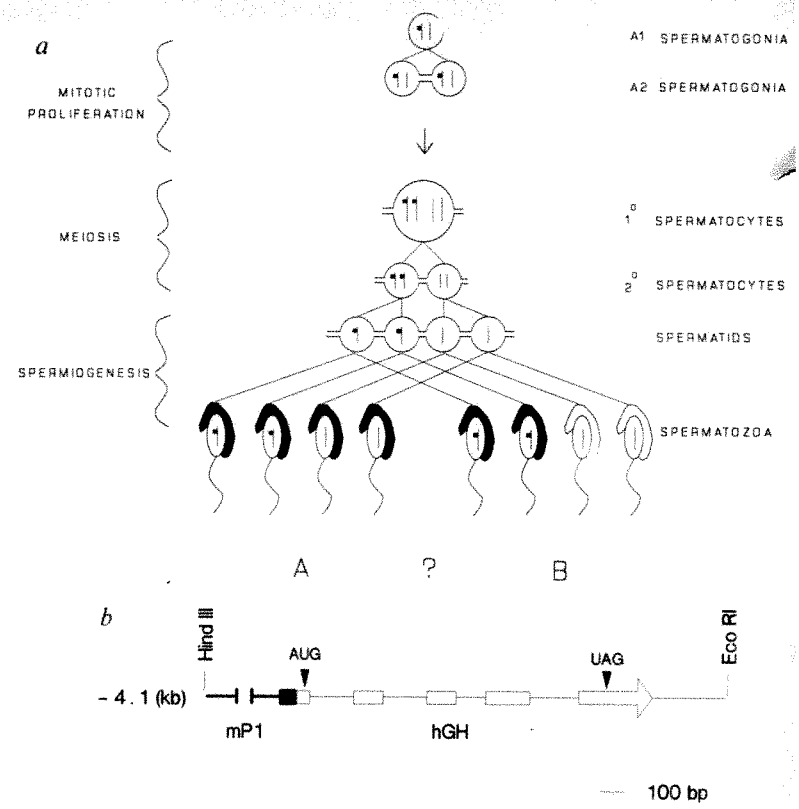

Fig. 1 *a*, Illustration of the syncytial nature of spermatogenesis and the three general stages of development[20,21]. The spermatogonial cells are drawn with a pair of homologous chromosomes inside them with one chromosome containing the introduced transgene (shown by a solid box). After the commitment of A1 spermatogonial cells to differentiate there are five or six rounds of mitotic proliferation. The first cell division generating A2 spermatogonial cells is shown. Primary spermatocytes contain a 4N complement of DNA, that is, each chromosome is associated with a sister chromatid. Each primary spermatocyte gives rise to four spermatids, two that contain a wild-type chromosome and two that carry a chromosome with the transgene. During spermiogenesis, round spermatids are transformed into mature spermatozoa. The question is whether all of the spermatozoa contain the product of the transgene (in this case the hGH protein localized to the acrosome), as shown in A, or whether only those spermatozoa that contain the transgene will have the product, as shown in B. *b*, Plasmid *mP1-hGH* contains approximately 4.1 kb of *mP1* 5′ sequence, including the promoter and 91 base pairs (bp) of 5′ untranslated sequence fused to a genomic clone for the *hGH* gene. Boxes represent exons and lines represent either nontranscribed DNA or introns. Bold lines and the solid box represent *mP1* DNA whereas thin lines and open boxes represent *hGH* DNA. The break in the line that corresponds to *mP1* sequence denotes that portion of the transgene that is not drawn to scale. The positions of the translational start and stop codons in the first and last exon, respectively, are shown above the gene structure. Transgenic mice were constructed by microinjecting a 6.3 kb *Hin*dIII-*Eco*RI fragment containing the *mP1-hGH* gene, free of plasmid vector sequences, into the pronuclei of fertilized C57BL/6×SJL F2 mouse eggs[22]. Two lines of transgenic mice, 314-4 and 315-6, were generated and used for this study. Both lines contain multiple copies of the transgene integrated on one chromosome.

offspring was analysed for the presence of the transgene by hybridization with an *hGH*-specific radiolabelled DNA probe. Analysis of the progeny from three generations of outcrosses of transgenic with nontransgenic animals showed that the mice were hemizygous for the transgene (data not shown).

In situ hybridization was used to determine the developmental stage in which the transgene is first transcribed. Figure 2*a* and *b* shows serial sections of a testis prepared from a hemizygous transgenic adult male, and hybridized with ^{35}S-labelled antisense RNA probes specific for the *mP1-hGH* transgene and the endogenous *mP1* gene, respectively. In both cases expression was detected exclusively in the haploid spermatids and not in spermatogonial cells or in spermatocytes.

Northern blot analysis of RNA isolated from the testis of prepuberal transgenic animals of different ages supported the conclusion that the transgene was expressed exclusively in post-meiotic cells. No transcripts were detected from the transgene or the endogenous gene in testis from 19-day-old animals, an age at which cells in the first cycle of spermatogenesis have progressed to the pachytene spermatocyte stage[9,10], whereas transcripts from both genes were detected, in about equal abundance, in 25-day-old animals, an age at which some cells have progressed into the haploid stage of development (data not shown).

To determine the phenotype of spermatids with respect to the product of the *mP1-hGH* transgene we used immunocytochemical analysis. Spermatozoa from transgenic mice harbouring the *mP1-hGH* construct contain the hGH protein localized in the acrosomal compartment (R.E.B. *et al.*, in preparation). Visualization of the hGH protein in developing acrosomes in early-stage seminiferous tubules (Fig. 3*a*), and in later-stage tubules (Fig. 3*b*), showed that the majority of the spermatids within a tubule of a hemizygous mouse were immunopositive for the hGH protein. Immunocytochemistry performed on the caput epididymis (the proximal portion of the epididymis where newly formed spermatozoa reside), showed that the hGH protein was stable in the acrosome and that, once again, most of the spermatozoa were immunopositive (Fig. 3*c*).

To quantitate the percentage of hGH-immunopositive spermatozoa, we isolated sperm from the caput epididymis (Fig. 3*d*) and determined directly the percentage that were immunopositive. Approximately 90% of all caput sperm analysed from hemizygous animals contained hGH-immunopositive acrosomes (Table 1), despite the fact that the gene was transmitted to only 50% of the offspring, showing that post-meiotic gene products can be shared.

Failure to detect hGH protein in 9% of the spermatozoa could be due to incomplete movement of RNA or protein between spermatids, nondetectable levels of expression of the transgene in some spermatids, or technical problems such as loss of the acrosome during the sperm isolation. To distinguish between incomplete movement of RNA or protein between the intercellular bridges and the other possibilities, we analysed caput sperm from mice homozygous for the transgene. Even in homozygous mice only 92% of the sperm were immunopositive (Table 1),

Table 1 Quantitation of the percentage of hGH-immunopositive spermatozoa

Genotype	Total sperm analysed	Percentage immunopositive
Hemizygous	2,185	91%
Homozygous	2,768	92%

Spermatozoa were isolated from the caput epididymis and immunocytochemistry was performed as described in the fig. 3 legend. These results were obtained by analysing spermatozoa isolated from three hemizygous mice (two from the 315-6 line and one from the 314-4 line) and two homozygous mice (both from the 314-4 line). Homozygous mice were obtained by crossing hemizygous transgenic animals and screening the offspring by quantitative DNA dot hybridization with an *hGH*-specific probe. Cells were counted using differential interference contrast microscopy at ×400 magnification.

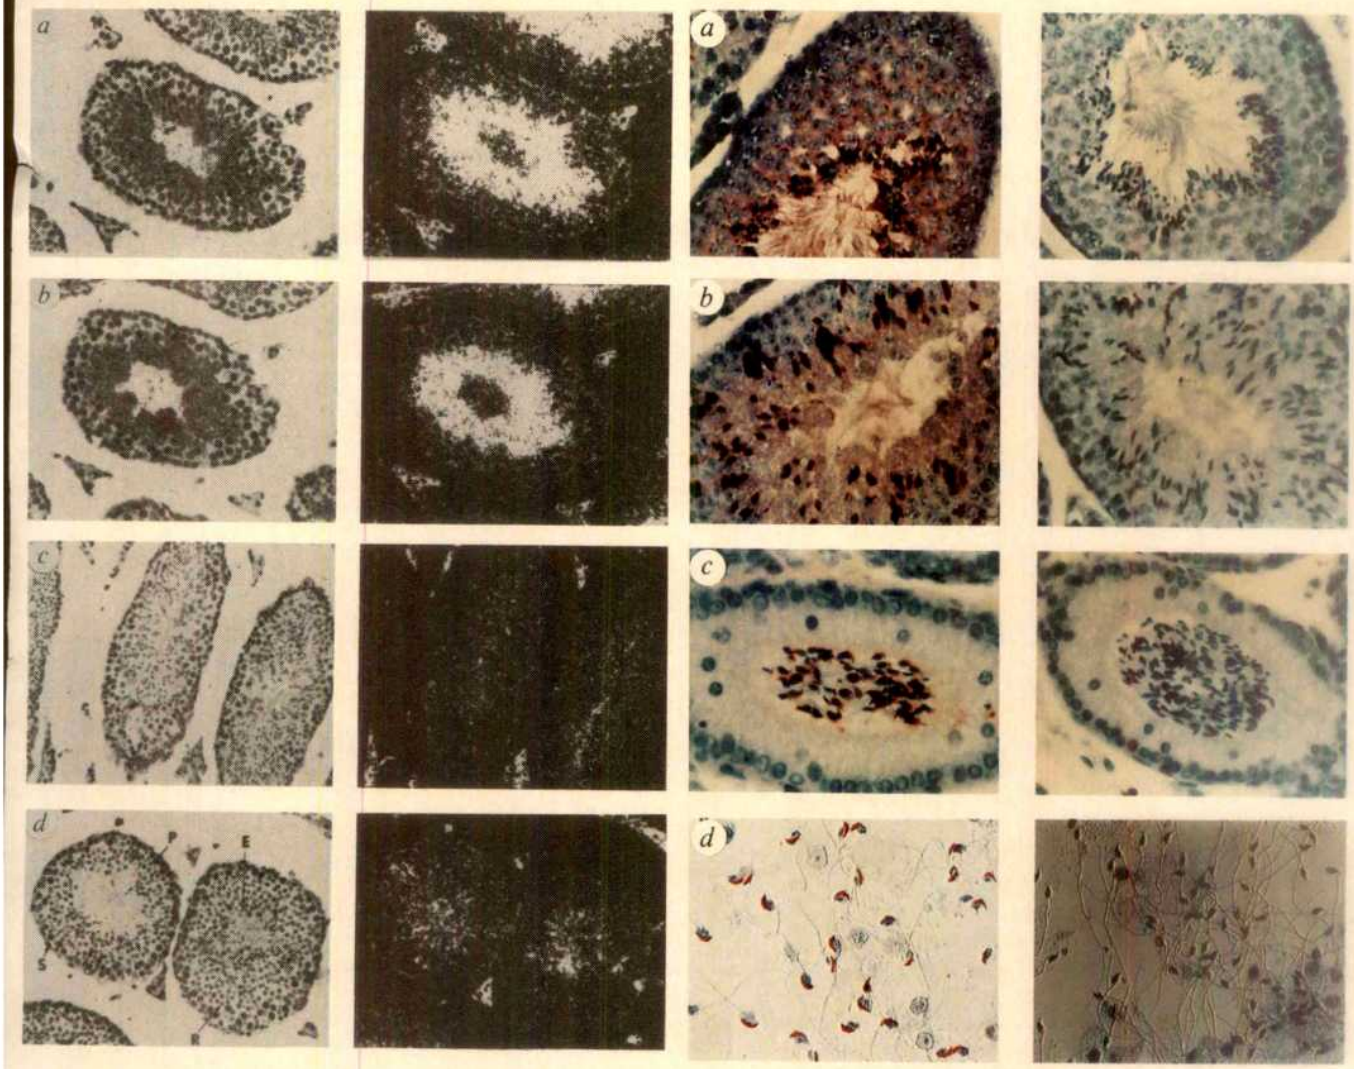

Fig. 2 *In situ* hybridization of testis sections from a transgenic mouse harbouring the *mP1–hGH* gene (line 314-4). Serial sections were hybridized with ^{35}S-labelled probes: *a*, *hGH* antisense RNA; *b*, *mP1* antisense RNA; *c*, *hGH* sense RNA; and *d*, *mP1* sense RNA. Photographs on the left were taken with bright-field microscopy and those on the right with dark-field microscopy. Examples of the different cell types found within a seminiferous tubule are shown by arrows and are labelled as follows: S, spermatogonial cell; P, pachytene spermatocyte; R, round spermatid; and E, elongated spermatid.

Methods. Single-stranded ^{35}S-containing sense and antisense riboprobes were made *in vitro* with linear templates and either SP6 or T7 RNA polymerase. The *mP1* template was made by cloning a 250-bp restriction fragment containing a portion of *mP1* exon 1, the intron, and a portion of exon 2 into pGEM-2. The *hGH* template was constructed by cloning a 170 bp restriction fragment containing *hGH* exon 5 into pGEM-2. Testes were fixed in 4% paraformaldehyde, embedded in paraffin, and cut into 5 μm sections. Hybridizations were as described[23]. Probes were used at a concentration of about 0.2 ng μl^{-1} with a specific activity of approximately 5×10^5 c.p.m. ng^{-1}. Hybridizations were at 45° overnight. The most stringent washing conditions were at 45° in 0.1 × SSC. Slides were developed after one to three days. Sections were counterstained with haematoxylin.

suggesting that it is not incomplete sharing of post-meiotic gene products that leads to the immunonegative cells.

Development of the acrosome occurs adjacent to the nucleus during spermiogenesis[9,11,12]. Juxtaposed to the acrosome is the cellular machinery responsible for synthesizing the acrosomal enzymes, the Golgi apparatus and the rough endoplasmic reticulum (RER)[12,13]. Because hGH protein is localized to the

Fig. 3 Immunocytochemistry of hGH protein in *mP1–hGH* transgenic mice (line 314-4). Photographs on the left show sections incubated in the presence of both the primary antibody (rabbit anti-hGH), and secondary antibody (biotinylated goat anti-rabbit IgG). Photographs on the right show sections incubated only in the presence of the secondary antibody. *a*, An early-stage seminiferous tubule with round spermatids at the CAP phase of acrosome development[9]. *b*, A late-stage tubule with many elongated spermatids and fully developed acrosomes. *c*, A section through the caput epididymis. *d*, Spermatozoa isolated from the caput epididymis. The hGH protein is seen as a red precipitate.

Methods. Testes were fixed in Carnoy's, embedded in paraffin and cut into 5 μm sections. Sections were deparaffinized with xylene and re-hydrated using standard procedures. Indirect immunocytochemistry was performed using the reagents and suggested protocols of Vectastain ABC and Zymed SABC kits. The primary antibody, rabbit anti-hGH, was obtained from the National Hormone and Pituitary Program, Baltimore, Maryland, and used at either a dilution of 1/100 or 1/500. Aminoethyl carbazole (Zymed Lab. Inc.) was used as the substrate chromogen. Sections were counterstained with haematoxylin. Additional negative controls included the use of both the primary and secondary antibodies on testes isolated from nontransgenic animals. For the isolated epididymal sperm, transgenic animals were killed, the caput epididymis dissected out and cut into 8–10 pieces, and incubated for 30 min at 30 °C in EKRB media[24]. After 30 min the supernatant was removed, centrifuged for 5 min at 1,000 r.p.m., and the pellet resuspended in a small volume of EKRB media. A few μl of sample were spread onto a microscope slide, allowed to dry for about 1 min, and fixed in Carnoy's. After incubation in PBS for 30 min, immunocytochemical analysis was performed as described above.

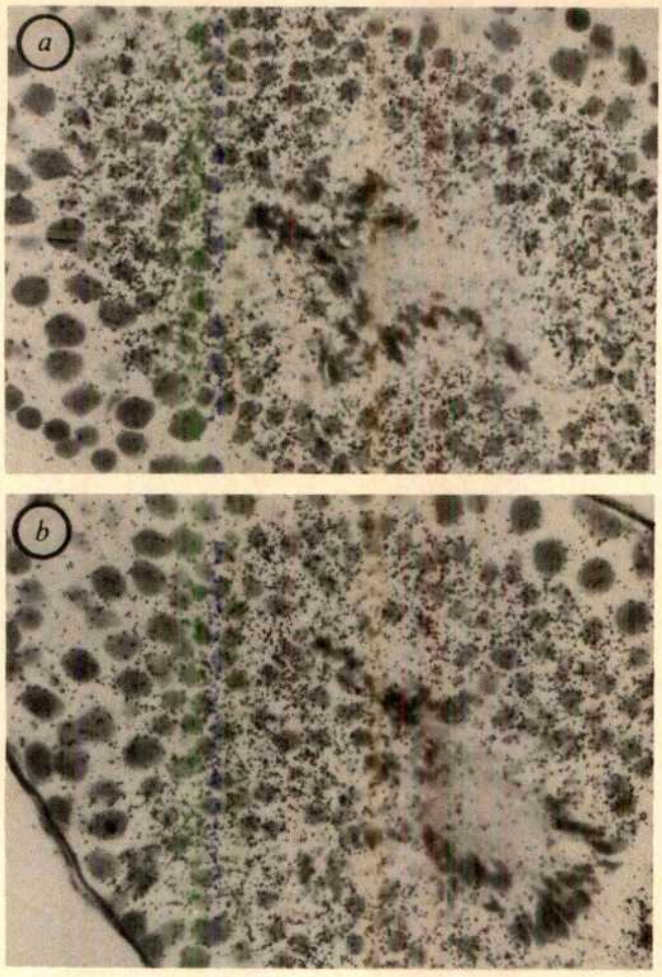

Fig. 4 *In situ* hybridization of testis serial sections hybridized with either an *hGH* antisense probe (*a*) or an *mP1* antisense probe (*b*). Sections were photographed at ×500 magnification. See Fig. 2 legend for details of hybridization conditions.

acrosome, it is probably synthesized on the RER, at the site of acrosome formation, and is therefore not free in the cytoplasm[14]. We first detect hGH immunocytochemically in the developing acrosome (Fig. 3*a*). Although it is unlikely that vesicles bud off from the Golgi and move between the syncytial bridges, electron microscopy studies have shown that the endoplasmic reticulum does sometimes extend through the bridges[15] suggesting that growth hormone protein could be traversing the bridges through the ER. Comparison of serial sections hybridized with *hGH*-specific and *mP1*-specific RNA probes (Fig. 4*a*, *b*), however, showed that within a seminiferous tubule there seemed to be an equal distribution of silver grains over all of the round spermatids regardless of the probe used. These results suggest that there could be movement of *mP1-hGH* mRNA, presumably through the intercellular syncytial bridges. Experiments designed to test unequivocally for movement of mRNA are currently in progress.

These results provide evidence against functional differences between sperm arising from post-meiotic gene expression. Our results are supported genetically, with one exception, by the absence of any cases of non-mendelian inheritance in the mouse[16]. The one exception involves preferential transmission of the t locus in male mice heterozygous for the t chromosome[17]. Male mice heterozygous for a complete *t*-haplotype can transmit the t-haplotype chromosome with a frequency as high as 99%[18]. Although transmission ratio distortion in *t*-haplotypes might be due to preferential retention of mRNA and/or protein in spermatids in which they are synthesized[16,19], it has yet to be demonstrated that post-meiotic transcription is definitely involved in the transmission ratio distortion. Our data do, however, clearly show that, at least for the product of the *mP1-hGH* transgene, either mRNA and/or protein is free to move between the intercellular bridges which connect developing spermatids, and suggest that the products of most genes may be equally distributed among spermatids.

We thank our colleagues for critical review of this manuscript and M. Avarbock, F. Oram and D. Allen for technical assistance. This work was supported in part by the NIH.

Tnt1, a mobile retroviral-like transposable element of tobacco isolated by plant cell genetics

Marie-Angèle Grandbastien, Albert Spielmann* & Michel Caboche

Laboratoire de Biologie Cellulaire, I.N.R.A., Centre de Versailles, 78026 Versailles Cedex, France
* Present address: ORSAN-RECHERCHE, 91953 Les Ulis Cedex, France

Transposable elements can be identified by their ability to induce mutant alleles at new loci. The retrotransposon family is thought to transpose through an RNA intermediate and has many similarities to vertebrate proretroviruses[1,2]. In plants, retrotransposons have been described in maize[3,4], *Arabidopsis*[5] and wheat[6], and non-viral retroposons in maize[7]. Most of these elements, however, have been found as non-mobile integrated units. Here, we report the isolation of the first tobacco (*Nicotiana tabacum*) transposable element, Tnt1, which seems to be the most complete mobile retrotransposon characterized in higher plants. Tnt1 has been isolated after its transposition into the nitrate reductase (NR) structural gene of tobacco, and transposition events have been detected through *in vitro* selection of spontaneous NR-deficient (NR^-) mutant lines in cell cultures derived from tobacco mesophyll protoplasts. Tnt1 is 5,334 nucleotides long, contains two 610-base-pair-long terminal repeats and a single open reading frame of 3,984 nucleotides. Comparison of the Tnt1 open reading frame coding potential with those of the *Drosophila melanogaster copia*

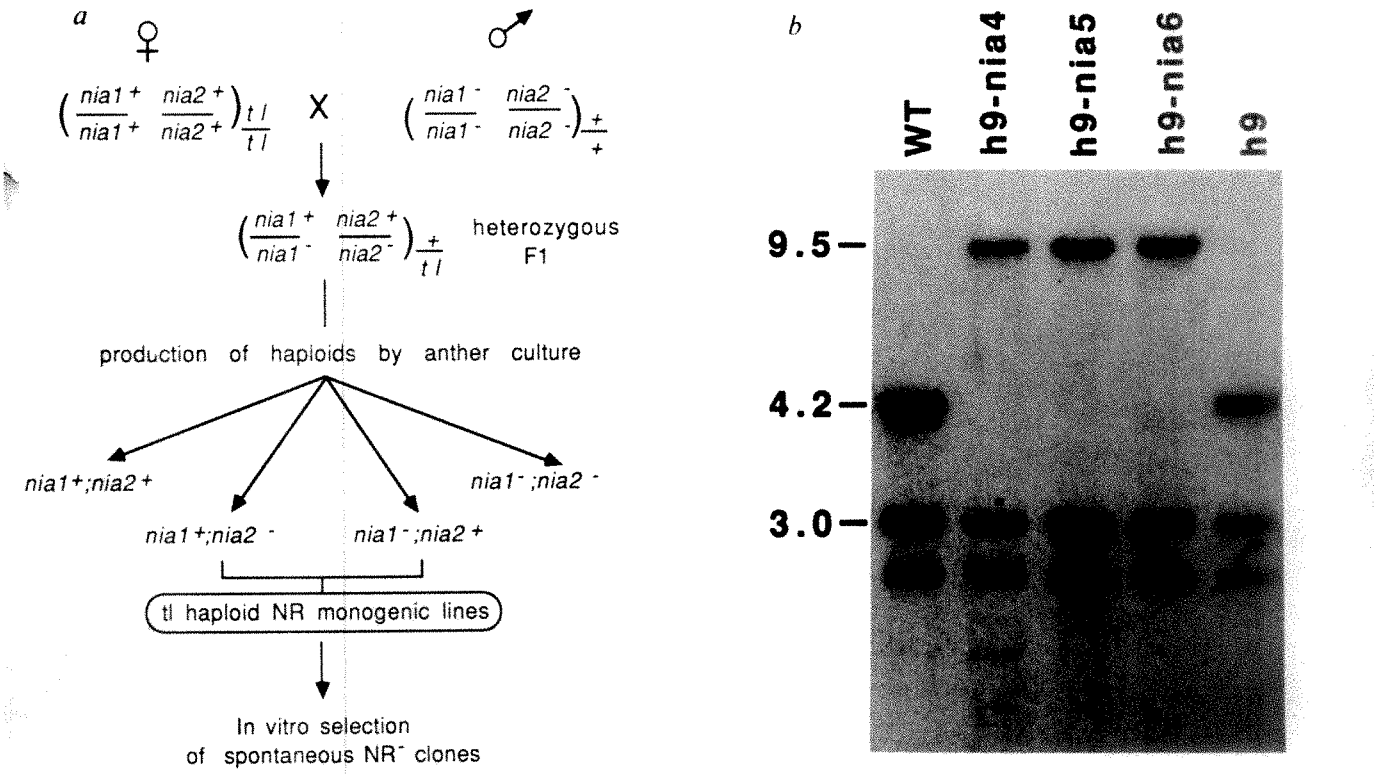

Fig. 1 Isolation and characterization of three spontaneous NR⁻ mutants induced by transposition of Tnt1 into the coding sequence of the *nia2* locus. *a*, The construction of haploid monogenic lines from which spontaneous NR⁻ clones were selected. Stably mutated *nia* alloalleles from a NR⁻ (*nia1*⁻; *nia2*⁻) tobacco line[12] were introduced into a NR⁺ (*nia1*⁺; *nia2*⁺) tl line by crossing and subsequent anther culture[29] of the F1. Haploid NR monogenic tl lines (*nia1*⁺; *nia2*⁻) or (*nia1*⁻; *nia2*⁺) were screened by genetic tests on derived diploidized plants[29]. Mesophyll protoplasts were isolated[30] from haploid lines and spontaneous chlorate-resistant clones were selected on derived colonies[13]. The NR deficiency of these clones was confirmed by their inability to grow on nitrate as the sole nitrogen source. NR⁻ plants were regenerated and propagated in the greenhouse by grafting[31]. *b*, Southern blot analysis of *Eco*RI restriction digests of total DNA isolated from three independent NR⁻ mutants selected in cell cultures from the h9 (*nia1*⁻; *nia2*⁺) tl monogenic line. WT = wild-type XHFD8 tobacco line[29]. Structure of the stably mutated *nia* genes originating from the NR⁻ line[11] is similar to the wild-type *nia* genes[14]. The probe was a 1.6 kb *Eco*RI NR cDNA fragment which hybridizes similarly to both alloalleles, revealing a 3 kb band from the wild-type *nia1* gene and a 4.2 kb band from the wild-type *nia2* gene. An additional 2.8 kb band shows homology to the probe, but is not correlated to the *nia1* or *nia2* structural genes[14]. In the three h9-Nia4, h9-Nia5 and h9-Nia6 mutants, the *nia2* 4.2 kb *Eco*RI fragment has disappeared and a new 9.5 kb band is present. Sizes are in kb.

Methods. Total plant DNA was isolated by a modified Dellaporta procedure[32] and purified on a CsCl gradient. DNA (5–6 μg per lane) was digested and Southern blot analysis was performed as previously described[11].

retrotransposon[8], yeast Ty retrotransposon[9], and vertebrate pro-retroviruses[2] revealed that Tnt1 is closely related to *copia* and carries all the functions known to be required for autonomous transposition by reverse transcription.

The primary aim of this work was the isolation of a transposable element thought to be responsible for a chlorophyllian somatic instability in a mutant tobacco line named tl (ref. 10). We used cell genetic techniques to detect the transposition of this element into the NR structural gene, for which a cDNA molecular probe was available[11]. Tobacco is an amphidiploid species arising from the combination of two diploid genomes of wild-type *Nicotianeae* species. To induce nitrate reductase deficiency, two functional homoeologous genes (*nia1* and *nia2*) encoding the apoenzyme of nitrate reductase have to be simultaneously mutated in the haploid tobacco genome[12]. Haploid NR monogenic tl lines were constructed, in which one of the two *nia* alloalleles is stably mutated, and in which a single transposition event can induce a NR⁻ phenotype (see Fig. 1*a*). Spontaneous NR⁻ clones were selected from mesophyll protoplast-derived cells by a direct selection for resistance to chlorate[13]. Several spontaneous NR⁻ clones were isolated at frequencies of up to 10^{-4} and regenerated into plants. Molecular analysis of regenerated NR⁻ plants showed that this phenotype was associated, in one-third of the clones analysed, with a modification of the restriction pattern of the wild-type *nia* alloallele. In three independent NR⁻ mutants selected from the h9 NR monogenic line (*nia1*⁻; *nia2*⁺), the 4.2 kilobase (kb) *Eco*RI fragment present within the wild-type *nia2* gene[14] has disappeared and a new hybridizing band of about 9.5 kb is present (Fig. 1*b*). More detailed restriction mapping revealed that an insertion of 5.3 kb was located into the first exon of the *nia2* gene in mutant h9-Nia6, the second in mutant h9-Nia5, and the third exon in mutant h9-Nia4 (data not shown).

To isolate the 9.5 kb *Eco*RI band, partial genomic libraries were constructed in phage λ NM1149 (ref. 15) from mutants h9-Nia4 and h9-Nia5, and screened with the NR cDNA probe. Clone LNM94 was isolated from the h9-Nia4 library and clone LNM95 was isolated from the h9-Nia5 library. In both clones, a 5.3 kb insertion is found at the expected location in the *nia2* gene. The structure of the *nia* regions adjacent to the insertion is similar to the structure of the wild-type gene, indicating that no other DNA rearrangement has occurred in the two mutants. Both insertions cross-hybridize and have similar restriction maps (Fig. 2), indicating that the NR⁻ phenotype is due to the transposition of the same mobile element into the *nia2* gene. The element is, however, inserted in opposite orientation in each mutant. This transposable element has been named Tnt1 (for transposable element of *Nicotiana tabacum*).

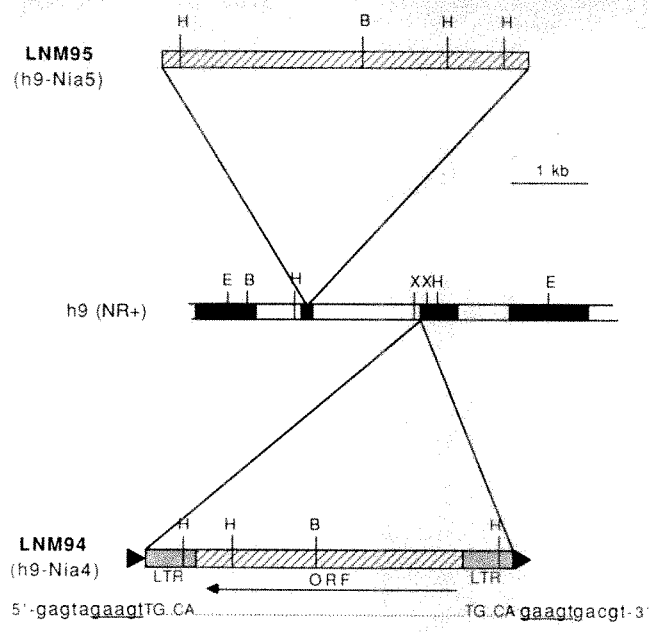

Fig. 2. Restriction maps of the two Tnt1 insertions found in clones LNM94 and LNM95. A restriction map of the NR^+ (h9) *nia2* *Eco*RI fragment is shown for reference. Some structural features of the Tnt1 element of LNM94 are shown. Dark boxes represent the coding sequence of the *nia2* gene, hatched boxes the Tnt1 insertion, and shaded boxes the LTRs. Arrow indicates the Tnt1 ORF orientation. The sequence of LTR terminal inverted repeats is represented in capital letters, the sequence of the *nia2* gene[14] in lower-case letters, and the sequence of the target site duplications (dark triangles) is underlined. B = *Bam*HI, E = *Eco*RI, H = *Hind*III and X = *Xho*1.

Methods. Plant DNA (150 μg) was digested by *Eco*RI and fractionated on sucrose gradient as described[33]. Fractions containing the 9.5 kb band hybridizing to the NR cDNA probe were purified and ligated to the insertion vector λ NM1149 (ref. 15). Because of the high instability of the Tnt1 insertion, further purifications of positive recombinant clones, and subcloning in pBluescript (Stratagene) were performed on $recA^-$ host strains.

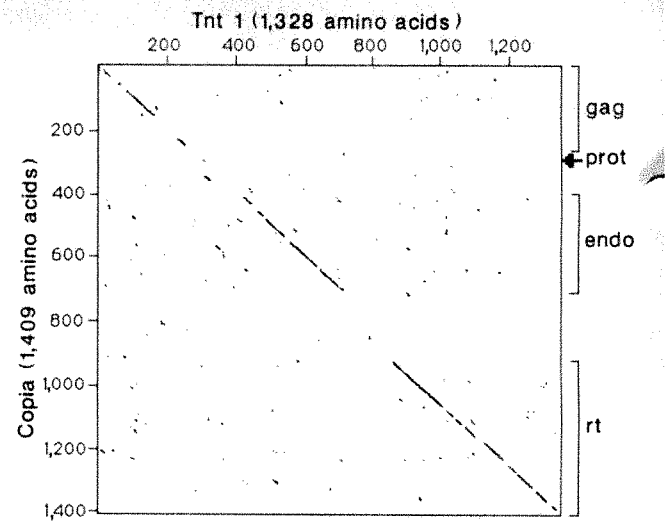

Fig. 3 Homology matrix comparisons between amino-acid sequences of the Tnt1 and the *copia* ORFs. A computer program[34] was used to generate diagonal lines indicating segments of 20 residues that show similarity above a threshold level. Residue numbers are indicated. The approximate regions corresponding to *gag*, and the endonuclease (endo) and reverse transcriptase (rt) domains of the *pol* gene are shown. The active site of the protease (prot) is indicated by an arrow. Respective positioning of all these regions are similar in Tnt1 and *copia*. In proretroviruses and retroviral-like elements, the *gag* gene encodes for the structural core proteins, and the polyprotein encoded by the *pol* gene is maturated by cleavage in several functional units, which are mainly the protease, the endonuclease and the reverse transcriptase. No homology to the *env* region of retroviruses has been found in *copia* and Tnt1.

Methods. Average score values were calculated for pairs of segments of 20 residues, whose amino-acid sequences were compared between Tnt1 and *copia*. If the average score value is greater than 238, a diagonal line is generated on the corresponding position of the homology matrix. This threshold value is the degree of similarity that would occur by chance with a probability of less than 2×10^{-4}. All the computer analyses were performed using the programs available from the Centre Interuniversitaire de traitement de l'Information (CITI 2, Faculté de Médecine, Paris).

The complete sequence of the Tnt1 element found in the mutant h9-Nia4 was determined by the dideoxynucleotide method[16]. Tnt1 is 5,334 base pairs (bp) long and is flanked by a duplication of a short region of host DNA (5 bp) at the integration site. Tnt1 has structures typical of transposable elements of the retrotransposon family (Fig. 2). It is bounded by two identical long terminal direct repeats (LTRs) of 610 bp, which are terminated by the consensus sequence 5'TG . . . CA-3'. Moreover, Tnt1 internal features include most of the structural and functional regions commonly found in retrotransposons and retroviruses. Sequence analysis of the 4,115 bp internal domain of Tnt1 has revealed a single large open reading frame (ORF) of 1,328 amino acids, oriented in the opposite direction to the *nia* coding sequence in the h9-Nia4 mutant. The putative protein encoded by the Tnt1 ORF was compared with retroviral gene products[17-19] and the putative protein encoded by *copia* ORF[8]. The general organization of the Tnt1 ORF is very similar to the one in *copia*, both in overall structure (*gag-pol*) and in length (1,328 amino acids in Tnt1, 1,409 in *copia*). At the amino-acid level also, a high degree of homology was found between the putative polyproteins encoded by the ORFs of these two elements (Fig. 3): 29% homology for the *gag* polyprotein product (residues 1-265), 42% homology for the endonuclease domain of the *pol* polyprotein product (residues 420-720), and 38% homology for the reverse transcriptase domain of the *pol* polyprotein product (residues 810-1,328 for Tnt1 and 890-1,404 for *copia*). Similarities include several short stretches of amino acids that are highly conserved in all proretroviruses and retrotransposons, which are summarized in Fig. 4. The *gag* regions of *copia* and Tnt1 contain a 14-amino-acid domain located at exactly the same position in both ORFs (amino acids 232-245), which is highly conserved among retroviral nucleic acid-binding proteins[20]. These proteins are required for accurate positioning of the tRNA primer on the replication initiation site at the 5' end of the RNA genome[21]. In most retroviruses and retrotransposons, the 5' end of the *pol* gene codes for a protease involved in the processing of polyproteins. The conserved sequence Asp-Thr(Ser)-Gly is replaced in Tnt1 by the Asp-Thr-Ala sequence, which presumably could also act as an active site of the protease[22]. Moreover, this sequence is found at comparable locations in Rous sarcoma virus (RSV), *copia* and Tnt1 elements, and the relative spacing between this site and the nucleic acid-binding domain is similar in the three genomes. Regions of highest homology between the Tnt1 ORF and *copia* also include conserved domains identified among a wide variety of reverse transcriptase and polymerase gene products[23-25]. One of the most highly conserved domains was found at amino acids 1,005-1,014 of the Tnt1 ORF (amino acids 1,012-1,021 of the *copia* ORF). This region (Tyr-Met or Val-Asp-Asp followed by strictly hydrophobic long-chain amino acids) is found not only in reverse transcriptases, but also in RNA-templated viruses[26]. The 3' region of the *pol* gene of a variety of vertebrate retroviruses also encodes an endonuclease[1,23]. In Ty and *copia*, there is homology to this region at the 5' end of the *pol* gene[8], as in Tnt1.

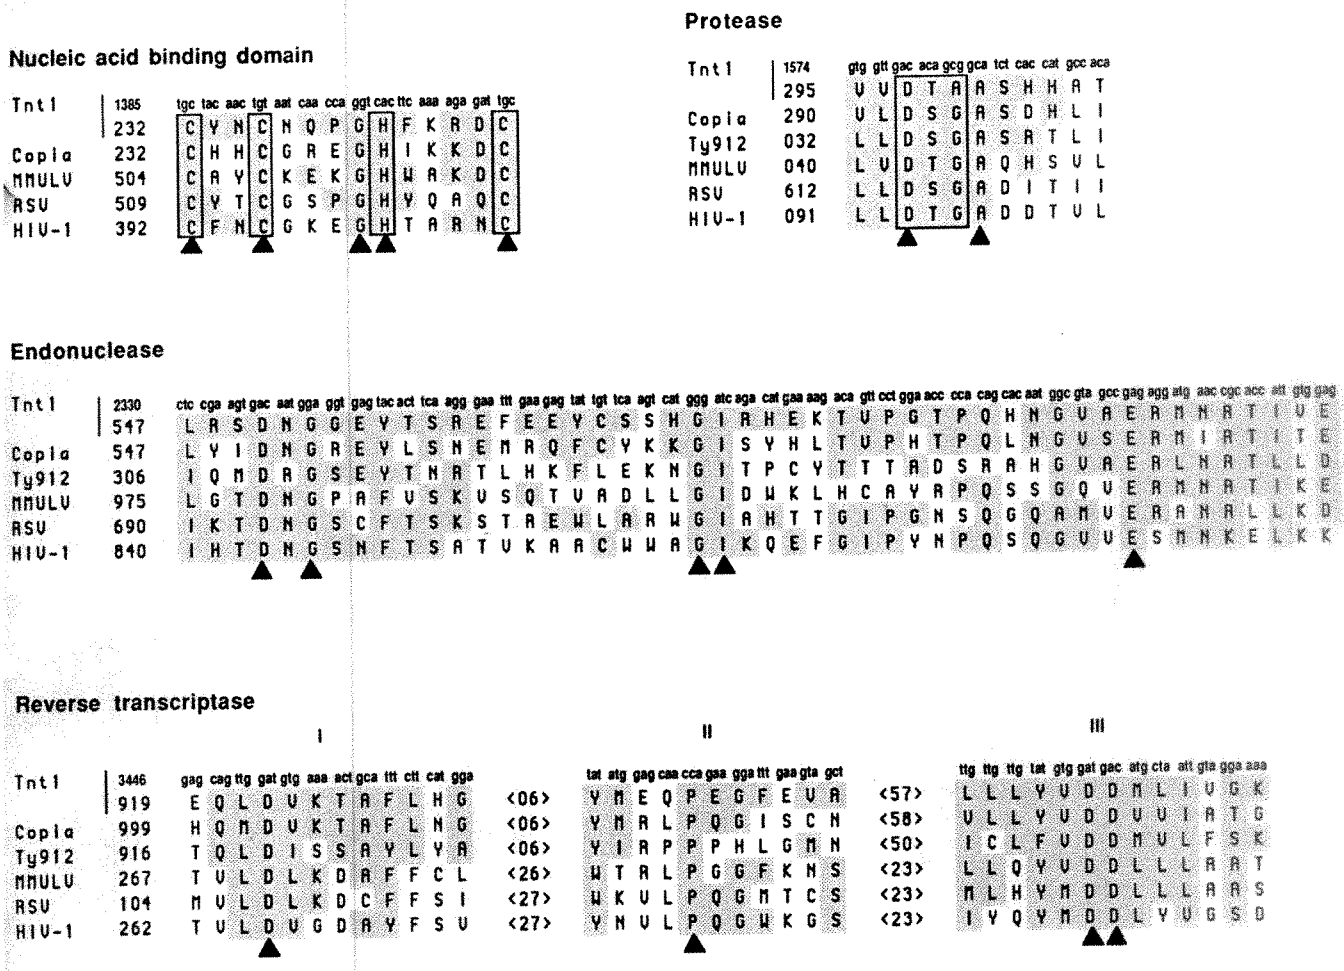

Fig. 4 Comparison of the Tnt1 ORF with conserved domains found in retroviruses and retrotransposons. Amino-acid sequences are indicated in capital letters, and the corresponding nucleotide sequence for Tnt1 is indicated in lower-case letters. Conserved and nearly invariant amino acids are shaded. Fully conserved positions are indicated by arrows. *Copia* is a retrotransposon from *Drosophila melanogaster*[8]; Ty-912 is a member of the retrotransposon family Ty1 in *Saccharomyces cerevisiae*[9]; MMULV is the Moloney murine leukemia virus[17]; RSV is the Rous sarcoma virus[18]; HIV-1 is the human immunodeficiency virus[19]. Alignments are those previously published[23–25]. Nucleic acid-binding domain[20]: the cysteine and histidine residues involved in the zinc-binding domain are boxed. Protease domain[22]: the conserved D-T-(S)-G amino-acid sequence is boxed and numbers indicate amino-acid positions, starting from *gag* (Tnt1, *copia* and RSV), *pol* (MMULV, HIV-1) or ORFb (Ty-912). In the endonuclease domain[23], only the most highly conserved domain is represented. In the reverse transcriptase domain, the three motifs are compared as in ref. 25 and the length separating the motifs is indicated between brackets.

From these sequence comparisons, we conclude that the Tnt1 ORF encodes a polyprotein containing the necessary functions for its autonomous transposition by reverse transcription of an RNA intermediate: the gag core proteins[2], a protease[22], a reverse transcriptase and an endonuclease[1,23]. The high degree of amino-acid sequence conservation over the entire length of Tnt1 and *copia* ORFs indicate that Tnt1 is highly related to *copia*, and suggests that they might share a common ancestral origin, raising the question of possible horizontal transmission of such elements between insects and plants.

Whether Tnt1 is active in the plant throughout the life cycle, or only at defined stages of development, is not known. Tnt1 might have been activated by tissue culture, as reported for Ac in maize[27]. Experiments are in progress to detect RNA species related to Tnt1, as well as potential hybrid transcripts of the *nia2* gene containing Tnt1 insertions.

The presence of Tnt1 in wild-type tobacco and several other plant species was investigated by Southern blot analysis with a probe specific to Tnt1 (data not shown). This element is present at very high copy number (at least 100 copies per haploid genome) in wild-type and tl tobacco, and in *Nicotiana plumbaginifolia*. Cross-hybridization was also found in other *Solanaceae* species (*Petunia hybrida*, *Solanum tuberosum*, *Lycopersicon esculentum*). These results suggest that Tnt1-related sequences were present in the *Solanaceae* family during the very early stages of speciation. No cross-hybridization could be detected with a number of other dicotyledon and monocotyledon species (*Arabidopsis thaliana*, *Sinapis alba*, *Beta vulgaris*, *Cucumis sativus*, *Trifolium repens*, *Medicago sativa*, *Pisum sativum* and *Zea mays*).

The relationship between the high somatic instability of the tl mutation and the activity of Tnt1 is hypothetical. Retrotransposons are known to excise at very low frequencies, by recombination between LTRs. It is therefore possible that Tnt1 is not involved in the tl unstable mutation. In maize, however, the Adh1-S5446 mutation caused by insertion of Bs1 has been described as highly unstable[28].

No previous example of the use of transposable elements for the *in vitro* selection of biochemical mutants at the somatic level has yet been reported in plants. Until now, gene tagging in plants has required screening of large populations of plants for visible mutation. If suitable cellular systems are available, new ranges of mutations can be obtained by selection at the cell level, and the type of approach described here could therefore extend the potential of transposable elements as genetic engineering tools in eukaryotes, especially in plants.

We are grateful to A. Deshayes for original support of this work and for providing the tl tobacco mutant, and to P. Rouzé for valuable assistance in computer data analysis. We thank A. Müller for providing the original NR⁻ tobacco line, C. Missonier, J. Goujaud and M. F. Dorbe for technical help, and H. Vaucheret for valuable advice. We thank J. P. Bourgin for constant encouragement, our colleagues of the Laboratoire de Biologie cellulaire for helpful discussion, and M. Kavanagh, C. Robaglia and M. Vincentz for detailed comments on the manuscript. This work was supported by a grant from the M.R.E.S. DNA sequence data will be available in the EMBL/GenBank/D.D.B.J. Nucleotide Sequence Databases under the accession number X13777.

Note added in proof: A quick analysis of the amino-acid sequence homologies between Tnt1 and the Ta1 retrotransposon recently isolated in *Arabidopsis*[5] has given the following approximations: endonuclease (integrase) domain, 42%; reverse transcriptase domain, 52% (D. Voytas, personal communication). Both elements seem therefore to be more closely related to each other than to *copia*.

The relationship of a prochlorophyte *Prochlorothrix hollandica* to green chloroplasts

Seán Turner*, Tineke Burger-Wiersma†, Stephen J. Giovannoni*‡, Luuc R. Mur† & Norman R. Pace*

† Laboratory for Microbiology, University of Amsterdam, Nieuwe Achtergracht 127, 1018 WS Amsterdam, The Netherlands

It is generally accepted that chloroplasts arose from one or more endosymbiotic events between an ancestral cyanobacterium and a eukaryote[1]. Such an origin fits well in the case of the chloroplasts of rhodophytes that, like cyanobacteria, contain chlorophyll *a* and phycobilin pigments[2]. The green chloroplasts from higher plants, green algae, and euglenoids however, contain chlorophyll *b* as well as chlorophyll *a*, and lack phycobilins. Consequently, it has been suggested that they arose independently of the rhodophyte chloroplasts, from an ancestral prokaryote containing that complement of pigments[3]. The 'prochlorophytes' *Prochloron didemni* (an exosymbiont on didemnid ascidians[4,5]) and *Prochlorothrix hollandica* (a recently discovered, free-living, filamentous form[6]) have been suggested to be modern counterparts of the ancestor of the green chloroplasts because they are prokaryotes that also contain both chlorophylls *a* and *b*, and lack phycobilins[7,8]. We report here a 16S rRNA-based phylogenetic analysis of *P. hollandica*. The organism is found to fall within the cyanobacterial line of descent, as do the green chloroplasts, but it is not a specific relative of green chloroplasts. Thus, similar pigment compositions do not necessarily reflect close evolutionary relationships.

Analysis of RNase T1-generated oligonucleotide catalogues of 16S rRNA from several samples of *Prochloron* sp. indicated that this symbiont falls within the cyanobacterial line of descent, but it seemed to be more closely related to the filamentous, heterocystous cyanobacteria of the genera *Nostoc* and *Fischerella* than to green chloroplasts[9,10]. This interpretation of the data has been disputed for methodological reasons[11]. Although the inability to cultivate *Prochloron* sp.[12] has retarded the investigation of its biochemistry and molecular biology, the discovery of *P. hollandica*[6] provided a tractable model for detailed investigations of prochlorophytes. The presence of chlorophyll *b* in *P. hollandica* suggests that it might be the closest known, free-living relative to the green chloroplasts.

At present, the best method for evaluating evolutionary relationships is the comparison of homologous macromolecular sequences. The 16S rRNA was the natural choice for the phylogenetic analysis of *P. hollandica* because of the broad database available, of cyanobacterial and chloroplast 16S rRNA sequences[13]. About 1,200 nucleotides of the *P. hollandica* 16S rRNA sequence were determined by dideoxynucleotide termina-

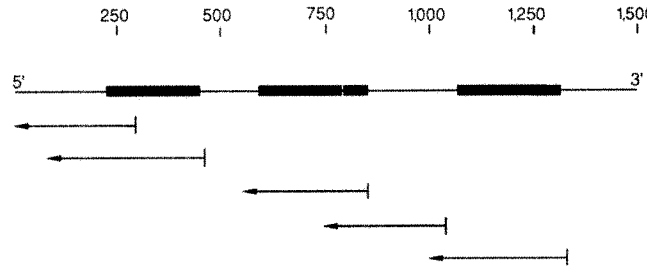

Fig. 1 Regions of 16S rRNA sequenced. *Prochlorothrix hollandica* cells were grown in liquid batch culture using medium BG-11[26]. Ribosomal RNA was obtained and purified as described[13], except that after phenol extraction and ethanol precipitation of the cell lysate, large rRNA was purified by electrophoresis on a denaturing 2.5% polyacrylamide gel. The band containing 16S RNA was excised from the gel and the RNA was electroeluted into 3M NaOAc (*p*H 5.5), followed by two rounds of ethanol precipitation. Dideoxynucleotide-terminated sequencing of 16S rRNA using reverse transcriptase and synthetic oligodeoxynucleotide primers was as described[13,27]. The *P. hollandica* 16S rRNA is represented as a line segment about 1,500 nucleotides in length. Arrows designate those regions of sequence determined from the the use of individual oligodeoxynucleotide primers. Thickened regions of the line segment represent the nucleotides used in the sequence analysis.

tion, using reverse transcriptase elongation from oligodeoxynucleotide primers on purified 16S rRNA (Fig. 1). The sequence has been depositied with GenBank and is available from the authors upon request. The inference of the evolutionary relationship of *P. hollandica* to other organisms used a distance matrix method to analyse 677 sequence positions that are approximately equally distributed among the three major domains of the 16S rRNA secondary structure[14] and are unequivocally homologous in all the organisms. The results are presented as a phylogenetic tree in Fig. 2.

P. hollandica is a deeply branching member of the cyanobacteria, most closely related to two unicellular forms, *Synechococcus* sp. strain PCC 6301 (*Anacystis nidulans*) and *Synechococcus* '*lividus*' strain CCC Y7C-S. *P. hollandica* is not specifically related, to the exclusion of other cyanobacteria, to the coherent phylogenetic grouping of the green chloroplasts and the cyanelle of *Cyanophora paradoxa*[13]. We feel that the continuous sequences of the cyanobacterial 16S rRNAs[13] do not overlap sufficiently with the RNase T1-generated, 16S rRNA oligonucleotide catalogues of *Prochloron didemni*[9] and the chloroplast of the red alga *Porphyridium* sp.[15] to allow the reliable inference of a phylogenetic tree that includes these latter components.

The assumption that all sequence positions are equally subject to change can lead to significant errors in the estimation of sequence divergence[16]. Although the likelihood of such errors decreases when sequences of closely related organisms are compared, the possibility of such an occurrence in our analysis was checked by inferring phylogenetic trees under the assumption that the rates of change of sequence positions are described by a log-normal distribution[17]. No differences in tree topology were found.

The reliabilities of several features of the inferred phylogeny were examined by a 'bootstrap' analysis of the data in which sequence positions were randomly selected, with replacement, to produce data sets that were analysed in the same manner as the original data set[18]. Twenty-five 'bootstrapped' phylogenetic trees were generated for this analysis. In 19 of them (76%), *P. hollandica* formed a coherent subgroup with *Synechococcus* sp. strain PCC 6301 and/or *Synechococcus* '*lividus*' strain CCC Y7C-S to the exclusion of all other members of the tree. In 23 'bootstrapped' trees (92%), *P. hollandica* formed coherent subgroups with one or both *Synechococcus* spp. and/or *Phormidium ectocarpi* strain PCC 7375. The association of the cyanelle of *Cyanophora paradoxa* with the green chloroplasts to form a coherent, exclusionary subgroup occurred in 22 'bootstrapped' trees (88%). In no instance did *P. hollandica* group

with one or more of the green chloroplasts or cyanelle to the exclusion of other organisms in the tree. This analysis firmly supports the conclusion that *P. hollandica* is not a specific relative of the green chloroplasts.

On the basis of these rRNA sequence comparisons, the closest known relative of green chloroplasts is the cyanelle of *C. paradoxa*. Cyanelles are believed to be the result of a relatively recent endosymbiosis between a cyanobacterium and a eukaryote[19]. This hypothesis is supported by the fact that cyanelles have both cyanobacterial and chloroplast-like features. Cyanobacterial qualities of cyanelles include a rudimentary peptidoglycan wall, and the presence of chlorophyll *a* and phycobilins. Cyanelles lack chlorophyll *b* and the membrane arrangements that are characteristic of green chloroplasts[19]. The chloroplast-like features of cyanelles include small genome size and genome organization[20,21]. Furthermore, as with chloroplasts, the expression of many cyanelle proteins is under the control of the eukaryotic host[22].

Some lineages that are not known to produce chlorophyll *b* diverged from the main cyanobacterial line at positions intermediate between the lines leading to the green chloroplasts and to *P. hollandica* (Fig. 2). This result implies that the ability to synthesize chlorophyll *b* arose independently in the ancestors of *P. hollandica* and the green chloroplasts, or that it was acquired by lateral transfer. Chlorophylls *a* and *b* differ in a minor way: the oxidation state of a single carbon (methyl in chlorophyll *a* but aldehyde in chlorophyll *b*) so the acquisition of the ability to synthesize chlorophyll *b* would not seem to be a significant biochemical change. A less likely interpretation of the phylogenetic relationships is that *P. hollandica* and the progenitor(s) of green chloroplasts shared an ancestor that produced chlorophyll *b*, but that multiple losses of the ability to synthesize chlorophyll *b* occurred among the intermediate cyanobacterial sublines. In any case, however, we must conclude that similar pigment compositions do not necessarily reflect particularly close evolutionary relationships.

All the currently available data indicate that cyanobacteria, prochlorophytes, and chloroplasts constitute a 'holophyletic' group; that is, a group that consists of a common ancestor and all lineages derived from it[23]. The creation of a new taxon, the Prochlorophyta, has been recommended to accommodate prokaryotes that contain chlorophylls *a* and *b* and lack phycobilins, to the exclusion of the cyanobacteria[24]. Such a taxon has been previously criticized on the grounds that pigment composition does not constitute sufficient evidence for the creation of a new taxon[25]. This report, that the ability to synthesize chlorophyll *b* occurs sporadically in separate lineages, shows that such a taxon would not constitute a natural grouping. It would be a 'polyphyletic' group, one composed of selected members of independent lineages.

psbA genes indicate common ancestry of prochlorophytes and chloroplasts

C. W. Morden & S. S. Golden*

Department of Biology, Texas A & M University College Station, Texas 77843, USA

It has long been suspected that chloroplasts evolved after an endosymbiotic event involving a photosynthetic prokaryote, presumably a cyanobacterium, and a eukaryotic organism. Recent studies have provided strong evidence about the cyanobacterial nature of chloroplasts[1]. Since the discovery of prochlorophytes[2], oxygen-evolving photosynthetic prokaryotes containing chlorophyll *a* and chlorophyll *b* and lacking phycobiliproteins, there has been speculation that these represent evolutionary intermediates between cyanobacteria and chloroplasts[3]. *Prochloron* sp., the first described prochlorophyte, proved difficult to work with because it is an obligate symbiont of marine ascidians[3]. *Prochlorothrix hollandica*, a recently isolated, freshwater filamentous prochlorophyte, is easily maintained in the laboratory[3,4]. Overall pigment composition and thylakoid membrane structure of *P. hollandica* suggest it has intermediate characteristics between cyanobacteria and the chloroplasts of higher plants[3]. The *P. hollandica psbA* genes, which encode the photosystem II thylakoid protein D1, were cloned and sequenced and the sequences compared to those reported for cyanobacteria, a green alga, a liverwort, and several higher plants. The two *psbA* genes present in *P. hollandica* encode an identical amino-acid sequence. As in all chloroplast *psbA* genes, there is a seven amino-acid gap near the C terminus of the derived protein relative to the protein predicted by cyanobacterial genes[5], suggesting that *P. hollandica* is part of the lineage that led to chloroplasts after a divergence from cyanobacteria. This hypothesis is also supported by phylogenetic analysis of derived D1 amino-acid sequences from *psbA* genes of thirteen taxa on the basis of parsimony.

Heterologous *psbA* gene probes from *Synechococcus* sp. strain PCC 7942 (ref. 6) were used to identify regions of sequence similarity in *P. hollandica*. These probes hybridized to two fragments when DNA was digested with either *Eco*RI (6.4 and 5.35 kilobases kb) or *Bam*HI (3.0 and 2.9 kb). Both *Eco*RI fragments were cloned and nucleotide sequence analysis revealed that each clone contained an entire *psbA* open reading frame (Fig. 1). The genes were named such that *psbAI* was sequenced from the 6.4 kb *Eco*RI fragment (which includes the 3.0 kb *Bam*HI fragment) and *psbAII* was sequenced from the 5.35 kb *Eco*RI fragment (which includes the 2.9 kb *Bam*HI fragment). Only two of the 1,059 base pairs (bp) in the open reading frame differed between the nucleotide sequences of the two genes. These differences represent silent transition mutations which did not alter the predicted polypeptide sequences encoded by these genes even though one, nucleotide 1,027, occurred in the first base position of a codon. The number of genes present and the nature of the predicted polypeptide is in contrast to the situation in both cyanobacterial and chloroplast genomes. Al

Fig. 1 Nucleotide and derived amino-acid sequences of the two *psbA* genes from *P. hollandica*. The nucleotide sequences upstream and downstream of the 1,059 bp open reading frame (ORF) are shown for *psbAI* and *psbAII*. Regions of sequence identity in the upstream and downstream regions of *psbAI* and *psbAII* are underscored. The nucleotide sequence of the *psbAII* ORF is shown in its entirety. Differences in the *psbAI* sequence are denoted above the *psbAII* sequence at positions 282 and 1,027. The single predicted amino-acid sequence for the protein encoded by both *psbAI* and *psbAII* is listed below each corresponding line of nucleotide sequence.

Methods. DNA was digested with *Eco*RI, ligated to *Eco*RI-cleaved λGT-10 cloning vector, and packaged *in vitro*. The library was plated on *Escherichia coli* host strain ER1458 (mcr⁻) and the resulting plaques were transferred to DuPont colony/plaque screen and probed with nick-translated[14] *psbA*-containing fragments from *Synechococcus* sp. PCC 7942. Positively identified plaques were picked, the phage amplified, and DNA isolated[14]. Cloned DNA was subcloned into plasmids for sequencing using a Sequenase dideoxynucleotide kit (United States Biochemical Corporation) and reactions were separated on a 7 M urea, 6% polyacrylamide gel[14]. Nucleotide sequences of different regions of both *psbAI* and *psbAII* were determined by a combination of subcloning restriction fragments, making nested deletions with exonuclease III, and preparing synthetic oligonucleotides from known regions of the genes to use a primers. Sequencing reactions were completed for each gene from overlapping clones to account for all bases on both DNA strands.

cyanobacteria that have been examined have three or more copies of *psbA* in their genomes which encode two different polypeptides[5,6] whereas the small circular chromosome of most chloroplasts contains a single copy of *psbA*[7].

The predicted D1 polypeptide of cyanobacteria contains 360 amino acids compared to 353 amino acids in *P. hollandica* and higher plants (352 amino acids in *Chlamydomonas*). Figure 2 shows a comparison of the C-terminal region of the D1 protein predicted from *psbA* genes from various cyanobacteria, eukaryotic species, and *P. hollandica*. Plastid and *P. hollandica* polypeptide sequences all share a seven amino-acid gap relative to the cyanobacterial sequences at a position six amino acids from the end of the polypeptide. The presence of well-documented insertion/deletion events in bacterial genomes has been implicated as a more reliable indicator of phylogenetic relationships than nucleotide or amino-acid sequences[8]: the definitive gap among the *psbA* genes of specific lineages suggests a more recent common ancestor among green plant chloroplasts and *P. hollandica* than among chloroplasts and cyanobacteria.

Cyanophora paradoxa (a photosynthetic protozoan) has been implicated as a descendant of the progenitor to green chloroplast-bearing organisms because of the presence of phycobiliproteins, rather than chlorophyll *b*, in the chloroplast-like cyanelle[9]. Comparisons of 16S rRNA sequences, however, show that *C. paradoxa* is not directly related to plastids and probably represents an independent endosymbiotic event[1]. They also suggest that a cyanobacterium, possibly similar to the endosymbiont of *C. paradoxa*, was probably the progenitor of chloroplasts[1]; however, a prochlorophyte was not included in that study. The *psbA* gene of *C. paradoxa* has recently been sequenced (W. Löffelhardt, personal communication). The seven amino acids characteristic of cyanobacterial sequences, but lacking in chloroplast-containing organisms, are present in the sequence of *C. paradoxa*. This strengthens the correlation between phycobiliprotein-containing organisms having a D1 protein of 360 amino-acid residues and chlorophyll *b*-containing organisms lacking the seven amino-acid domain at the C terminus of the protein. That *P. hollandica* also lacks this domain is further evidence that prochlorophytes, *P. hollandica* in particular, are members of the same lineage as the endosymbiont chloroplast progenitor which diverged from cyanobacteria. If prochlorophytes are not of this lineage, both chlorophyll *b* and *psbA* sequences shortened at the same position were derived independently in the two lineages.

As a further test to determine the relationships of *P. hollandica* to cyanobacteria and green chloroplast-containing organisms, the predicted polypeptide sequences of *psbA* genes from several species of vascular plants, a non-vascular plant, a green alga, four cyanobacteria, and *P. hollandica* were compared using PAUP, a computer program designed to determine phylogenetic

Fig. 2 Comparison of amino-acid sequences at the C terminus of the D1 polypeptide from different genera: *Anabaena*[5], *Fremyella diplosiphon*[15], *Synechococcus*[6], *Synechocystis*[16], *Chlamydomonas*[17], *Marchantia polymorpha*[18], spinach[19], soybean[20], alfalfa[21], *Prochlorothrix hollandica*. The C-terminal amino acids from residue 341 to the termination codon (*) are shown for each sequence, and those conserved among all sequences analysed are in bold type. Numerals following the genera *Anabaena*, *Synechococcus*, and *Synechocystis* refer to strain designations of the Pasteur Culture Collection. The *psbA* gene families of *Anabaena* sp. strain 7120 and *Synechococcus* sp. strain 7942 encode two slightly different D1 proteins; in each case the product of *psbA1* is designated by (1) and the product of the other members of the gene family is designated (2). Other plants with sequences identical to spinach in this region are *Amaranthus hybridus*[22], *Nicotiana debneyi*[19], *N. tabacum*[23], *Petunia hybrida*[24], and *Solanum nigrum*[25].

relationships based on parsimony[10]. Sequences of all taxa were aligned and were analysed by treating the gap region in four different ways: (1) excluding amino acids at positions 348–354 of cyanobacterial sequences from the analysis to compare the 353 remaining amino acids; (2) treating the seven amino-acid positions in the gap region as a single binary character (that is, presence or absence of this domain); (3) weighting each position of the gap region by 0.14 so the entire region is equal to a single character change with no loss of information at each position; (4) considering each position of the gap region as a separate and unique character. When amino acids of the gap region were completely excluded from the analysis (treatment 1), 30 equally parsimonious trees were produced, 15 of which were similar to that shown in Fig. 3 and 15 that associated *P. hollandica* in a lineage with the two *Synechococcus* sequences. The additional trees within each of these are accounted for by polychotomies and minor differences in topology of branches leading to higher plants. When the gap region was included in the analysis in any way (treatments 2, 3 or 4), tree topology was the same as in Fig. 3 with the major difference among the four treatments being the length of the branch (labelled *a*) leading to *P. hollandica* and chloroplast lineages: *a* was shortest in treatment 1 and longest in treatment 4 (data not shown). The length of each branch on the tree reflects the number of character state differences unique to that branch and the amount of divergence from a most recent common ancestor. The phylogenetic trees produced thus corroborate the phylogeny inferred from the gap distribution which places *P. hollandica* closer than cyanobacteria to green plant chloroplasts.

The predicted rate of divergence among highly conserved genes in bacteria has been estimated to be approximately 1% per 50 million years (Myr)[11,12]. The percentage similarity among *P. hollandica psbA* nucleotide sequences and those of *Anabaena* or *Synechococcus* range from 81.6% to 83.6% for the six genes examined, which would place the time of divergence between the cyanobacterial and prochlorophyte lines at about 900 Myr ago. This figure is within the range (800–2,000 Myr ago) previously predicted for the time of divergence between plastids and cyanobacteria based on 16S rRNA comparisons[11,12].

With the discovery of a third member of the *Prochlorophyta* which occupies deep marine euphotic zones[13], studies on this interesting group should continue to contribute to our understanding of the phylogeny of chloroplasts. Because *P. hollandica* is easily grown in culture[3,4] and represents an organism that

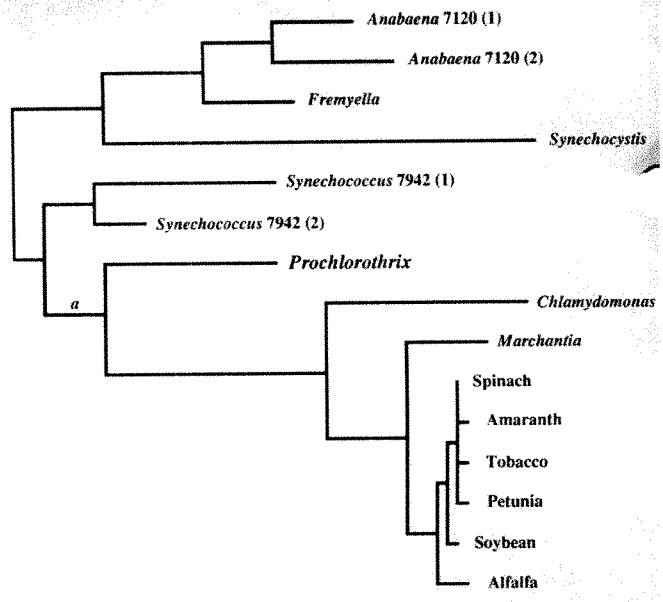

Fig. 3 Phylogenetic tree based on parsimony[10] among amino-acid sequences derived from *psbA* gene sequences of thirteen species. Branch length reflects the number of character state differences unique to that branch and the amount of divergence from a most recent common ancestor, but is not meant to depict evolutionary time. The branch labelled *a* was found to be variable in length among the four different analyses (see text). Gene designations for *Anabaena* sp. strain PCC 7120 and *Synechococcus* sp. strain PCC 7942 are as in Fig. 2. Sequences identical to that of spinach and not shown are *Nicotiana debneyi*[19] and *Solanum nigrum*[25]. Data for sequences were obtained from the same data set as in Fig. 2.

Methods. 118 positions along the amino-acid sequences were variable for at least one of the 15 sequences analysed. Amino acids were converted to a numeric character for each of the variable positions. The following numbers of equally parsimonious trees were generated for each of the four treatments used to compare sequences: (1) 30 trees, (2) 15 trees, (3) 15 trees, and (4) 15 trees. The order of branching was the same in all trees for treatments 2–4 and in half of the trees generated using treatment 1 (see text), with some minor differences in the branching order of higher plants. Amino acids 348–354 at the C terminus of cyanobacterial sequences were excluded from the analysis which produced this tree. All data were considered unordered and the tree was produced rooted at the midpoint of the greatest patristic distance using the branch-and-bound option of PAUP[10].

seems to be more chloroplast-like than cyanobacteria, *P. hollandica* may serve as a useful model organism for the study of oxygenic photosynthetic mechanisms.

We thank Drs George Bullerjahn, Ming-Che Shih, Jim Golden, and Steve Smith for their advice or assistance on various aspects of this work. This research was supported by a minigrant from Texas A & M University and an NIH Biomedical Research Support Grant through Texas A & M University.

Bacterial growth blocked by a synthetic peptide based on the structure of a human proteinase inhibitor

Lars Björck*, Per Åkesson*, Martin Bohus†, Jerzy Trojnar‡, Magnus Abrahamson§, Isleifur Olafsson§ & Anders Grubb§

Cysteine proteinases are important not only in the intracellular catabolism of peptides and proteins[1] and in the processing of prohormones and proenzymes[2,3], but also in the penetration of normal human tissue by malignant cells[4] and possibly microorganisms[5], including viruses. Cystatin C is a human cysteine proteinase inhibitor present in extracellular fluids[6]. We have synthesized peptide derivatives mimicking the proposed proteinase-binding centre of cystatin C[7] and find that they irreversibly inhibit cysteine proteinases. Several bacteria produce proteinases, so we tested a tripeptide derivative (Z-LVG-CHN_2) for *in vitro* anti-bacterial activity against a large number of bacterial strains belonging to thirteen different species. It was found to inhibit specifically the growth of all strains of group A streptococci. The susceptibility of these human pathogens to the peptide was compared with that to well-established anti-streptococcal antibiotics such as tetracycline and bacitracin. Moreover, the peptide was active *in vivo* against group A streptococci: mice injected with lethal doses of these bacteria were cured by a single injection of Z-LVG-CHN_2. The cysteine proteinase produced by group A streptococci was isolated and found to be inhibited by Z-LVG-CHN_2; moreover, excess proteinase relieved the growth inhibition caused by the peptide derivative, suggesting that the antibacterial activity of Z-LVG-CHN_2 is due to inhibition of this cysteine proteinase. This strategy of blocking proteinases with peptide derivatives that mimic naturally occurring inhibitors could be useful in the construction of new agents against other microorganisms, including viruses.

Of the peptide derivatives we synthesized to mimic the inhibitory reactive site of cystatin C (ref. 7), *N*-benzyloxycarbonyl-leucyl-valyl-glycine diazomethyl ketone (Z-LVG-CHN_2) most effectively inhibited papain, a model cysteine proteinase (association rate constant, $k'_{+2} = 600{,}000\ mol^{-1}\ s^{-1}$). The peptidyl portion of Z-LVG-CHN_2 was acting as a supersubstrate for the inhibited cysteine proteinase; the diazomethyl ketone group established a covalent link with the cysteine residue in the active site of cysteine proteinases[9], thereby making Z-LVG-CHN_2 an irreversible inhibitor.

Many microorganisms produce proteinases, so we investigated the effect of Z-LVG-CHN_2 on bacterial growth. Paper discs were impregnated with the synthetic inhibitor and applied to plates streaked with different bacteria (see legend to Fig. 1). Growth of all group A streptococcal strains tested was inhibited to a degree comparable with that shown by some well established antibiotics (Fig. 1); all other strains were unaffected by Z-LVG-CHN_2. We then analysed the anti-streptococcal activity of Z-LVG-CHN_2 in infected mice using a strain of group A streptococcus virulent in mice (strain 40/58). Ten outbred NMRI mice (ALAB, Sweden) were injected intraperitoneally (i.p.) with 10^6 streptococci in Todd–Hewitt broth. Thirty minutes later we injected (i.p.) five animals with 0.2 mg Z-LVG-CHN_2 in 0.5 ml 0.15 M NaCl in 1% dimethyl sulphoxide and five with 0.5 ml 0.15 M NaCl in 1% DMSO without Z-LVH-CHN_2. All mice in the control group died within 24 h, whereas among those treated with Z-LVG-CHN_2, one mouse died after three days and the

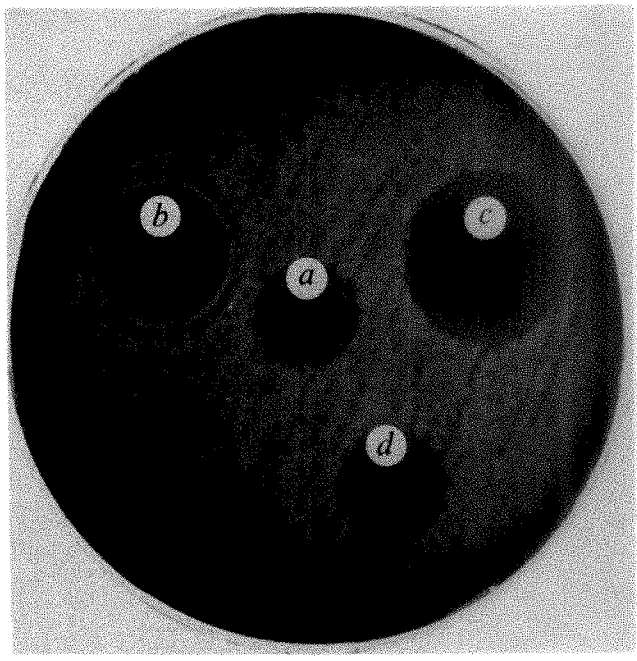

Fig. 1 Anti-bacterial activity of Z-LVG-CHN_2 in disc diffusion analysis.
Methods. Streptococci (strain 40/58 from the WHO Collaborating Center for Reference and Research on Streptococci, Institute of Hygiene and Epidemiology, Czechoslovakia) were plated on 0.8% purified agar in Todd–Hewitt broth containing 4% sheep's blood, and antibiotic-sensitivity discs were applied to the plate. In *a*, a non-impregnated disc had been prepared to contain 24 μg Z-LVG-CHN_2 by impregnating a sterile filter paper disc with 60 μl Z-LVG-CHN_2 (0.4 mg ml^{-1}) in 1% dimethyl sulphoxide in water. Disc *b* contained 30 μg doxycycline; disc *c*, 0.1 μg benzylpenicillin; disc *d*, 0.2 IU of bacitracin. All discs were from AB Biodisc, Sweden. Z-LVG-CHN_2 discs (24 μg per disc) were also used to screen a total of 190 strains of human pathogenic bacteria. All strains tested were from routine clinical specimens (Clinical Microbiology Laboratory, University Hospital in Lund). Species and number of strains were: *Staphylococcus aureus*, 12; *Staphylococcus epidermidis*, 14; group A streptococci, 28; group B streptococci, 14; group C streptococci, 19; group G streptococci, 11; *Streptococcus pneumoniae*, 8; *Streptococcus faecalis*, 10; *Branhamella catarrhalis*, 9; *Haemophilus influenzae*, 17; *Escherichia coli*, 22; *Klebsiella pneumoniae*, 15 and *Pseudomonas aeruginosa*, 11. All group A streptococcal strains showed a zone similar to *a* in the figure, with no bacterial growth surrounding the disc, whereas the other strains grew up to the edge of the Z-LVG-CHN_2-containing disc. In control experiments eight of the group A streptococcal strains were also tested against discs impregnated with 60 μl 1% dimethylsulphoxide or with 24 μg commercial (Sigma) cysteine proteinase inhibitor L-3-carboxy-*trans*-2,3-epoxypropionyl-leucylamido-(4-guanidino) butane (E-64). No inhibitory activity was shown by either the dimethylsulphoxide solution or by E-64.

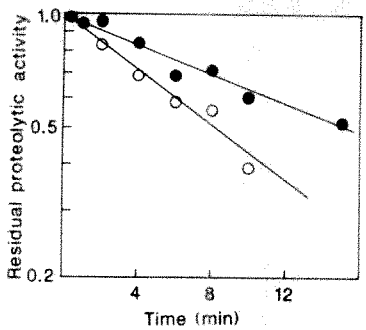

Fig. 2 Time-dependent inactivation of isolated streptococcal proteinase by 10 μM (●) or 20 μM (○) Z-LVG-CHN_2.

Methods. The streptococcal proteinase was isolated from growth medium of the streptococcal group A strain 40/58 from the Prague collection, as previously described[8]. The isolated enzyme was activated by preincubation at 25 °C during 1 h in 0.2 M sodium acetate/10 μM EDTA/50 μM dithiothreitol, *p*H 5.5. The activated enzyme (7.5 μg ml^{-1}) and Z-LVG-CHN_2 (from a stock solution in 1% dimethylsulphoxide) were mixed in the activation buffer at zero time. Samples were taken out at timed intervals and immediately added to assay tubes containing the chromogenic substrate Z-Lys-ONp (*N*-α-carboxybenzoyl-L-lysine-paranitrophenyl ester HCl (Bachem) at a final concentration of 0.2 mM. After 20 min at 25 °C, the reaction was stopped by addition of buffered chloroacetate, and the absorbance was read at 340 nm. A time-dependent inactivation of the enzyme was found. The residual proteolytic activity in the samples as a function of time gave a linear semilogarithmic plot typical of an irreversible second-order reaction. The rate of inactivation ($t_{0.5}$) at different Z-LVG-CHN_2 concentrations (10 μM and 20 μM) was dependent on the concentration of Z-LVG-CHN_2 ([*I*]). The apparent rate constant for association between enzyme and inhibitor, k'_{+2}, was then calculated as $\ln 2/t_{0.5}[I]$ (ref. 10).

remainder were still alive after two months. In a repeat experiment, all five control animals died within 24 h and the five mice treated with Z-LVG-CHN_2 survived (four weeks observation time). We then investigated the toxicity of Z-LVG-CHN_2: no ill-effects were seen in four mice each injected i.p. with 2 mg in 5 ml 0.15 M NaCl in 1% dimethylsulphoxide (two months observation time). So Z-LVG-CHN_2 is atoxic even at doses tenfold higher than those necessary to cure lethal streptococcal infections in mice.

Although Z-LVG-CHN_2 could inhibit streptococcal growth both *in vivo* and *in vitro*, the molecular mechanism behind this activity was not clear. There is a cysteine proteinase that is produced by all group A streptococcal strains but which has not been identified in other bacterial species, including other species of streptococci; the enzyme is produced as a zymogen that can be transformed into an active proteinase by reduction[8]. We purified the zymogen to apparent homogeneity from growth medium containing the same group A strain as we used in the animal experiments, when we found that the activated enzyme was irreversibly inhibited by Z-LVG-CHN_2. The association rate constant (k'_{+2}) of the reaction was determined as 102 mol^{-1} s^{-1} (Fig. 2). Moreover, Z-LVG-CHN_2-mediated growth inhibition could be impeded by addition of the activated proteinase. These data indicate that Z-LVG-CHN_2 could be inhibiting growth of group A streptococci by blocking their cysteine proteinase. E-64 is a well-known cysteine proteinase inhibitor[10], whose activity against the isolated streptococcal enzyme is comparable with that of Z-LVG-CHN_2, but E-64 did not inhibit growth of group A streptococci. This might be explained by the relatively greater hydrophobicity of Z-LVG-CHN_2 facilitating penetration of the bacterial cell wall, or by the fact that Z-LVG-CHN_2 is recognized by a permease, whereas E-64 is not. On this basis, proteinase-inhibiting peptide derivatives could be made more useful for antimicrobial therapy if their N-termini were recognizable by permeases that permit efficient intracellular uptake[11].

The biological function of the streptococcal proteinase is n known, but our data indicate that blocking the enzyme inhibi growth of these bacteria both *in vivo* and *in vitro*, which suggest that the proteinase is essential for the multiplication of grou A streptococci. This is supported by the fact that we have s far been unable to isolate any mutants of group A streptococ devoid of the cysteine proteinase, neither have we seen an Z-LVG-CHN_2-resistant mutants of the 40/58 strain (frequenc less than 10^{-6}). It will be interesting to see which of the othe microorganisms that are known to require proteinases for multi plication and/or tissue penetration are affected by inhibitor that imitate supersubstrate sections of naturally occurring pro teinase inhibitors.

We thank Inga-Maria Frick and Ingbritt Gustafsson for tech nical assistance. This work was supported by the Swedis Medical Research Council, the Medical Faculty at the Universit of Lund, the Österlund Foundation, and the Anna-Gret Crafoord Foundation for Rheumatology Research.

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

Nature is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature*'s staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

CATEGORIES OF PAPER

Review Articles survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

GENERAL

All contributions submitted for publication in *Natu* should conform with these rules.

Manuscripts should be typed, double-spaced, with good-quality printer, on one side of the paper only. Fo copies are required, each accompanied by letter artwork. Four copies of half-tones should be include Reference lists, figure legends and so on should be separate sheets, all of which should be double-spaced a numbered. Copies of relevant manuscripts in press submitted for publication elsewhere should be include clearly marked as such. Revised and resubmitted man scripts should also be clearly marked as such and labell with their reference numbers.

Titles should say what the paper is about with the mi mum of technical terminology and in fewer than 80 cha acters. Authors should avoid active verbs, numeric values, abbreviations and punctuation and should inclu one or two key words for indexing purposes.

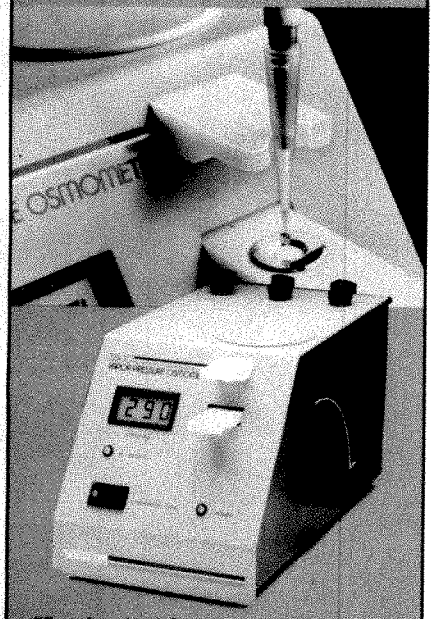
Artwork should be marked individually and clearly wi the author's name, figure number and, when know manuscript reference number. Original artwork shou be unlettered. Ideally, no figure should be larger than by 22 cm. Figures with several parts are permitted only the parts are closely related, either experimentally logically. Suggestions for cover illustrations, with ca tions, are welcome. Original artwork (and one copy of t manuscript) will be returned when a manuscript cann be published.

Colour Artwork. A charge of £500 a page is made for colour figures. Inability to meet these costs will not pr vent the publication of essential colour figures if the ci cumstances are explained.

Figure legends must not exceed 300 words and ideal should be much shorter, and should use telegraphic for wherever possible. The figure should be described firs then, briefly, the method. Reference to a method d scribed elsewhere is preferable to a full description Methods should not be described in detail in the text.

References should be numbered sequentially as the appear in the text, followed by those in tables and finall those in the figure legends. Reference numbers appl only to papers published or in the press, and a differe number should be given to each paper cited. All oth forms of reference (including unrefereed abstract should be included in the text as personal communicatio manuscript in preparation or preprint (with number an institution where appropriate). Text should not be incl ded in the reference list. References should be abbrev ated according to the *World List of Scientific Periodica* (fourth edition, Butterworth, London, 1963 – 65). Th first and last page numbers should be cited. Reference books should clearly indicate the publisher and the dat and place of publication.

Abbreviations, symbols, units and Greek letters should b identified the first time they are used. Acronyms shou be avoided as much as possible and, when used, define Editors will shorten words if necessary. In case of doub SI units should be used.



Footnotes should not be used except for changed addre ses or to identify the corresponding author if differe from the first-named.

Acknowledgements should be brief. Grant numbers an contribution numbers are not allowed.

Submission. *All manuscripts may be submitted to either London or Washington. They should not be addressed to editor by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' t prevent the imposition of import duty and value-added tax (VAT).*

The ideal way to measure osmolality.

The biotechnology explosion has expanded the need for measuring the osmolality of solutions. Such measurements are critical in many areas of research. The most current and accurate means of measuring osmolality is the Wescor Vapor Pressure Osmometer. More than 5,500 laboratories now use the Wescor VPO routinely.

Here's why it's so popular:

- Accepts any biological sample, including viscous liquids, tissue specimens and cell suspensions with no need to alter the physical state of the specimen.
- Accepts sample volumes as small as 2 microliters.
- Avoids measurement artifacts that often accompany freezing point measurements.
- Electronic accuracy and reliability without mechanical complexity.

If you are working with living cells or have other applications for accurate concentration measurements, investigate the Wescor VPO. It's the ideal osmometer.

PROTEIN KINASE INHIBITORS & ACTIVATORS

H-7, H-8, H-9, HA1004 | ML-7, ML-9 | SC-9, SC-10

The isoquinolinesulfonamide derivatives H-7, H-8, H-9, HA1004 and the newly synthesized naphthalenesulfonamide derivatives ML-7 and ML-9, are protein kinase inhibitors which exert their inhibitory effects by direct binding to the protein kinase molecule.

The naphthalenesulfonamide derivatives SC-9 and SC-10 are the first protein kinase C activators ever to be synthesized, and are extremely useful, in combination with H-7, for examining protein kinase C phosphorylation.

Over the years, history has shown that progress occurs through growth and development... our extensive research and development programme has resulted in a wide range of innovative products to meet the demands of today's Molecular Biologists. *GIBCO BRL's thorough testing and quality control programme gives our customers complete confidence in the reliability and reproducability of our products.*

The worldwide distribution network of GIBCO BRL *matches the quality of our products and a rapid, efficient delivery service combines with a high standard of technical support from some of the most experienced scientists in the field... so why not grow with* GIBCO BRL...

GIBCO BRL

Cationic liposome-mediated transfection

P.L. Felgner and G.M. Ringold

A lipid named DOTMA has been created that forms unilamellar liposomes which complex with DNA and RNA for the transfection of mammalian cells, including suspension cells and hybridomas.

EFFORTS to develop methods for functionally delivering polynucleotides into living cells have continued steadily over the past several years. Effective methods include the use of calcium phosphate, liposomes, retroviral vectors, reconstituted viral envelopes and electroporation. In addition, there are several procedures which employ polycations such as polylysine, DEAE-dextran and polyornithine[1-3].

Recently, a DNA delivery reagent was developed which consists of polycationic liposomes comprised of a positively charged lipid named DOTMA, for (*N*[1-(2,3 - dioleyloxy)propyl] - *N,N,N* - triethylammonium)[3]. The advantages of this reagent over other methods have been demonstrated for a variety of cell types, and include improvements in convenience, reproducibility, efficiency and efficacy.

The reagent is particularly notable for its ease of use. An aliquot of the aqueous reagent is simply added to the tissue culture experiment together with the DNA or RNA of interest. Although the level of observed expression is heavily dependent upon the cell line and expression vector, in the vast majority of cases, expression levels are at least comparable to — and frequently much greater than — those obtained with either the calcium phosphate or DEAE-dextran methods[3].

Mechanism of action

The postulated mechanism of action for the liposome reagent, based on experimental evidence, is illustrated in Fig. 1. DOTMA forms liposomes in an aqueous environment alone or together with other phospholipids[3,4], and the active reagent consists of sonicated vesicles containing equal parts of DOTMA and dioleoylphosphatidylethanolamine in water. DNA/DOTMA complexes form spontaneously after mixing an aliquot of the reagent with an aqueous solution of DNA[3], trapping nearly all of the polynucleotide in the complex interior.

The ratio of DOTMA to DNA is critical to the reagent's efficacy[3,5,6]. Theoretically, the optimal ratio should be such that the amount of positive charge contributed by the DOTMA liposomes slightly exceeds the number of negative charges on the DNA, so that the complexes have a net positive charge to facilitate their interaction with the negatively charged target cell surface. In practice, however, the optimum quantity of DOTMA is usually found to be roughly half this amount, and it is best to calibrate the concentration for each specific system to be studied.

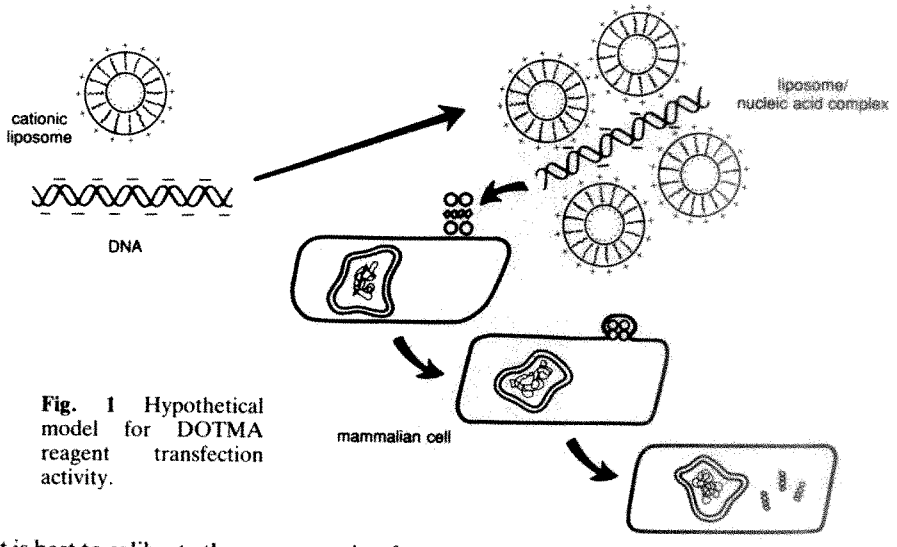

Fig. 1 Hypothetical model for DOTMA reagent transfection activity.

We hypothesize that DNA/DOTMA complexes consist of four liposomes in association with each plasmid. Liposomes that are 250 nm in diameter — the approximate size of the vesicles in our reagent — contain about 2,500 lipid molecules[7]. Half of the molecules in each liposome, or 1,250 molecules, are positively charged DOTMA molecules. Because 5,000 negative charges are present in a standard 2,500-base-pair plasmid, approximately four liposomes are necessary to neutralize the negative charges of the plasmid DNA. The average diameter of the complexes is only slightly larger than that of the original liposomes as measured by laser light scattering (unpublished data), indicating that they contain a very small number of plasmids (perhaps only one) per complex. Complexes containing a larger number of plasmids would show a substantial, measurable size increase.

Liposomes comprised of DOTMA and dioleoylphosphatidylethanolamine fuse with negatively charged lipid membranes and with cell surfaces[4]. Micrographs of cells exposed to fluorescent DNA/liposome reagent complexes which contain rhodamine-labelled lipid also indicate cell-surface fusion[3]. Comparable fusion results obtained with a positively charged lipid analogue which is structurally very similar to DOTMA have recently been published[8]. Liposomes comprised of stearylamine or dioctaldecyl-dimethylammonium bromide were inactive in transfection assays (unpublished data).

Different subpopulations of cells and cell types seem to take up DNA/DOTMA complexes with equal affinity. Following transfection with DNA/DOTMA complexes containing a fluorescent lipid analogue, essentially 100 per cent of cells become fluorescent[3]. Furthermore, cells exposed to radioactively labelled complexes adsorb 20-80 per cent of the added polynucleotide[6]. In a typical experiment in which 2 μg of a 2,500-base pair plasmid are exposed to one million cells (with approximately 10^6 plasmids per cell) about 500,000 plasmids would be expected to be taken up per cell. But at the end of a two-day transfection experiment with mouse L- cell fibroblasts, only 300 intact psV2-CAT plasmids per cell were recovered in the nuclear fraction (unpublished data), indicating that less than one per cent of the adsorbed plasmids were reaching the nucleus intact. In a parallel experiment using the calcium phosphate method, however, less than 10 plasmid copies per cell were found in the nucleus.

In histochemical staining experiments on cells transfected with β-galactosidase expression vectors, up to 25 per cent of the cells were positive. It is not known whether the remaining 75 per cent of the cells were truly negative, or whether they were expressing activity below the sensitivity of the staining procedure: experiments with double-stranded RNA clearly show that more than 99 per cent of the cells are transfected[5]. Stable transformation efficiencies of as high as 10 per cent have been obtained, although this varies depending on vector and cell type.

The transfection step is performed in serum-free media to overcome the effects of an inhibitory component present in serum. The duration of this incubation

period ranges from 2 to 24 hours. Because purified sulphated proteoglycans are potent inhibitors of DOTMA-mediated transfection (unpublished results), a similar polyvalent negatively charged serum component is presumably responsible for this effect.

The efficiency of the method is essentially unaffected by variances in *p*H between 6.0 and 8.0[3]. Where a *p*H difference of as little as 0.1 in a calcium phosphate transfection experiment can influence the result, it has no effect on the DOTMA reagent[1]. Precise mixing protocols, careful attention to the level of DNA, and the presence of low levels of contaminants are also less important to the outcome of DOTMA-mediated transfection experiments. In addition, large DNA molecules such as baculovirus DNA (130 kilobase pairs) have been successfully transfected into tissue culture cells using the technique (J. Barnett, personal communication).

Applications

Detailed quantitative data comparing the DOTMA reagent with other optimized transfection methods is available for only a few selected systems[3], but some general statements regarding relative efficacy are possible. As with all transfection methods, the transient expression levels and transformation efficiencies obtained are strongly dependent upon the particular expression vector and the cell line to be tested. In a number of cell lines, 10- to 100-fold improvements over other methods have been demonstrated[3]. The reagent has also been used to transfect cells unresponsive to other methods (such as PC12 cells), suspension cells and hybridomas. The DOTMA liposome reagent has been used successfully to transfect, both stably and transiently, over 50 cell lines and primary cell cultures.

Relatively crude preparations of plasmid DNA, such as those made in minipreps, can be efficiently introduced into cells using the reagent, allowing large numbers of different DNAs to be screened. For example, the products of site-directed mutagenesis can be conveniently transfected without time-consuming purification protocols.

Particularly exciting is the recent finding that the reagent is broadly applicable for the delivery and expression of messenger RNA in a wide variety of both adherent and suspension culture cell lines[5]. This has opened up a new experimental approach to the characterization of mRNA structure and function, areas that were not possible to study using more conventional transfection procedures. For example, the method has shown that the expression efficiency of mRNA synthesized *in vitro* is strongly dependent upon the presence of specific untranslated elements in the RNA construct[6]. The reagent has also been used successfully to deliver Sinbus virion RNA or *in vitro*-transcribed infectious RNA, resulting in active virus particles (S. Schlesinger, personal communication).

Despite the advantages offered by the liposome reagent, other transfection protocols may be more effective for some applications. A notable example is the optimized calcium phosphate procedure of Okayama[1], which gives excellent results in some cell lines. Similarly, for many suspension cultures, electroporation continues to be the only effective method for introducing nucleic acids. Despite these observations, the DOTMA-mediated transfection procedure stands out as one that can be broadly, successfully and conveniently applied to a a very wide variety of different cell types for both stable and transient expression, and which can be applied to other polynucleotides, including both double-stranded[5] and single-stranded messenger RNA[6]. Future studies with reagents of this type should reveal even more efficacious delivery systems for the introduction of small oligonucleotides, very large DNA fragments or even proteins into intact cells.

The DOTMA reagent is now commercially available from Bethesda Research Laboratories (Bethesda, Maryland USA) under the name Lipofectin. Still other cationic liposome delivery systems may eventually prove applicable to the delivery of polynucleotides *in vivo* for therapeutic applications. □

Cell-to-cell communication

Products for examining the intricacies of cell function will be on hand next week when the American Society for Cell Biology and the American Society for Biochemistry and Molecular Biology hold their joint meeting in San Francisco, California. Below are several examples.

PROMEGA now offers confidential **cDNA and genomic library construction** services *(Reader Service No. 101)*. The company will take polyadenylated RNA or genomic DNA, and construct a library using their line of vectors, including those prepared from lambda gt10, lambda gt11 and lambda gt11 *Sfi- Not*. These vectors allow cloning strategies such as directional cloning, subtraction library construction, and expression of cloned inserts as polypeptides fused with β- galactosidase. Each lambda library is packaged *in vitro* using Promega's Packagene extract, which the company says is prepared from a single strain devoid of *Eco* K activity to avoid destroying inserts with that restriction site. Promega will also isolate RNA from tissue, screen libraries, prepare plasmids and phage DNA, and produce antisera on a contract basis.

Benchtop power

Flow has a Cell Raiser of a **benchtop bioreactor** that prevents sleepless nights of worry and tedious trips to the lab to check growth parameters *(Reader Service No. 102)*. Flow's bioreactor of that name comes complete with its own data acquisition system, so researchers can keep an eye on fermentation data from home or a separate office using a modem. The Cell Raiser has built-in controls for *p*H, dissolved oxygen, agitation and temperature. Using its diagnostic software, the bioreactor's controller continuously tests its control loops, including tests for sensor operation and control elements. If any control value deviates from parameters set by the user, it sets off visual and

Flow's Cell Raiser bioreactor.

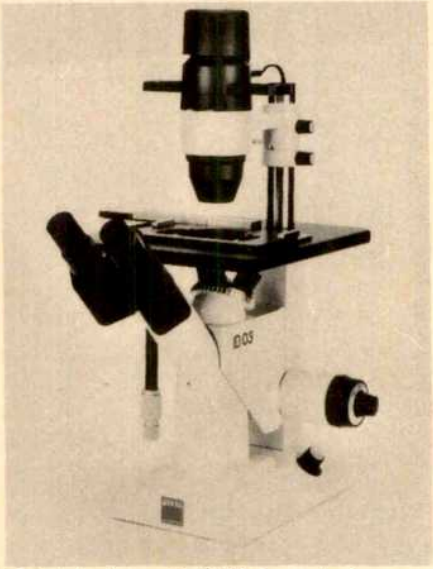
udible alarms. The computer can also be et to call users remotely via a modem to eliver alarm information. What's better, sers can alter parameter settings through he modem to fix minor problems.

Jouan has a **midrange benchtop centrifuge** that can be used to spin microtubes nd bottles — without changing the rotor *(Reader Service No. 103)*. Jouan's model 2312 centrifuge comes with rotors equipped with plastic insert modules onfigured for labware ranging from 0.5 nl tubes to 250 ml bottles. The modules

Jouan's benchtop centrifuge comes with modular plastic tube inserts.

allow several types of samples to be centrifuged in one run, in different wells of the same rotor. The microtube inserts can also be used as a tube rack, so that experiments can be whisked from the benchtop directly to the centrifuge. The centrifuge's horizontal T4 rotor achieves up to 3,600 r.p.m., generating 2,550 *g*. The fixed angle rotor generates up to 6,300 *g*. The C312 centrifuge comes in both a non- refrigerated version and a refrigerated version which has a temperature range of 0–30 °C.

Yamato has incorporated the innovative technology of molecular sieving into a **freeze dryer** that fits onto the lab bench *(Reader Service No. 104)*. Yamato has altogether eliminated bulky cooling mechanisms in its model DC41 freeze dryer: the unit silently "cages" sublimating water vapour molecules without dry



Yamato's bath-free freeze dryer.

ice, chilled alcohol baths or mechanical refrigeration. Heating the sieves releases the accumulated water and regenerates them for reuse. The freeze dryer has five ports, and can process 200 ml of sample at one time. Its instrument panel has a timer with a buzzer to signal the conclusion of the sublimination, and either a thermocouple vacuum gauge or a Bourdon Tube for measuring pressure in centimetres of mercury. The company says its freeze dryer is particularly useful for the preservation of temperature-sensitive biologicals.

The small world

Zeiss has rounded out its line of **inverted microscopes** with its low-priced model ID03 *(Reader Service No. 105)*. The inverted microscope features a new 6 V, 20 W illuminator with a diffusing disk that Zeiss says assures even illumination in brightfield techniques. It contains an aperture iris diaphragm and a three-position slider that allows it to be switched instantly from brightfield to either of two phase-contrast techniques. The new illuminator in the model ID03 has a working

Zeiss's basic model IDO3 inverted microscope comes with a host of features.

distance of 70 mm at 0.3 numerical aperture, and its housing has a flip-top for replacing the bulb.

Olympus's new SZH model **zoom stereomicroscopes** have a remote control facility for hands-free operation *(Reader Service No. 106)*. Focusing is controlled using a foot pedal — a feature that Olympus says is particularly useful when dissecting using micromanipulation tools. Firm foot pressure is used to make rapid movements, and fine focusing is controlled by pressing gently. An anti-crash sensor prevents damage to the specimen or microscope. Olympus SZH stereomicroscopes have an 8.5:1 zoom ratio and a potential magnification range of 3.75 × to 384 ×. The microscopes can also be equipped with remote control pedals for zoom function.

The Microvid **computer microscopy module** from Wild Leitz turns microscope eyepieces into a computer screen, so that data can be reflected into the microscope and photographed together with the image *(Reader Service No. 107)*. The Microvid projects text, graphics and

Text-processing meets microscopy in Leitz's Microvid computer microscopy module.

measuring scales onto the viewing image of any modern Leitz microscope through an optical link. The system fits onto the side of Leitz microscopes for measuring and marking the original microscope image, outside the darkroom. The Microvid's software performs measurements of area and perimeter, speed and time. Text can be input at any position on the image, in two different character sizes. Self-drawn and standard graticules can be faded in over the microscope image for sizing and precise counting.

DNA details

MilliGen/Biosearch, a division of Millipore Corporation, has announced the introduction of its model 8800 **large-scale DNA synthesizer** to meet the demand for

Large-scale DNA synthesis using β-cyanoethyl phosphoramidite chemistry.

large quantities of DNA in diagnostic and therapeutic applications *(Reader Service No. 108)*. The model 8800 is a modular, benchtop instrument controlled by an IBM PC workstation which MilliGen/Biosearch says can synthesize from 30 to 300 μmol of DNA at one time. The system has a batch reaction design which relies on base- dependent coupling and deblocking protocols. The fully programmable synthesizer has software which performs reagent calculations and has notebook capabilities. The standard protocols are based on β-cyanoethyl phosphoramidite chemistry, but the system can be adapted for other chemistries as well.

DNAStar, Inc. has a **compact disk** containing the Brookhaven Library of Protein Structures which allows researchers to view the structures of protein molecules in three dimensions by wearing stereo glasses *(Reader Service No. 109)*. The company developed the X★RAY disk as a less inexpensive adjunct to high-performance molecular workstations for protein chemists, and as an aid for students wishing to familiarize themselves with 3-dimensional protein structures. DNAStar says X★RAY rapidly paints the detailed composite molecular structures in colour stereo views on the screen of any IBM PC/AT/XT or PS/2 equipped with an EGA or VGA colour graphics monitor. The displayed molecules can be fully rotated with and without side chains, and can be printed out on a dot matrix or laser printer, or an HP Plotter.

Biotix, Inc. is introducing a **high-speed DNA synthesizer** at the San Francisco exhibition that it says is capable of pro-

Five-minute oligonucleotides with 99 per cent purity from Biotix.

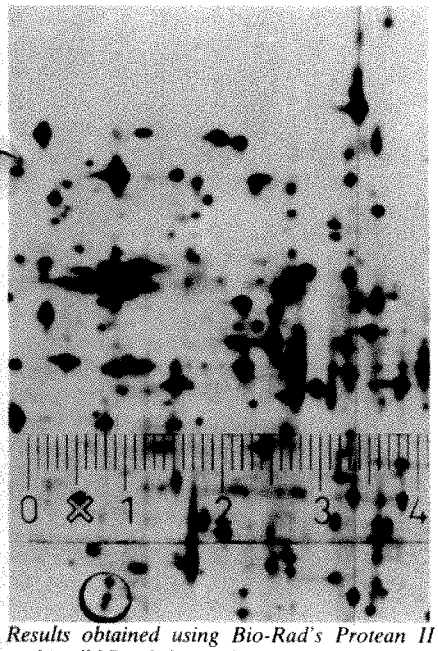
ducing high-purity oligonucleotides with 99 per cent efficiency in coupling cycles of under five minutes *(Reader Service No. 110)*. Both the one- and two-column models of the synthesizer are fully automated and user programmable. The synthesizer has a 200-mer capacity, and Biotix guarantees that it will synthesize oligonucleotides of up to 125 bases. The $14,950 single-column instrument comes complete with an IBM- compatible PC.

Perkin-Elmer Cetus is now producing **recombinant *Taq* DNA polymerase** for use in the polymerase chain reaction (PCR) for DNA amplification *(Reader Service No. 111)*. The company's AmpliTaq

Recombinant Taq *DNA polymerase from Perkin-Elmer Cetus comes singly or as a kit.*

DNA polymerase is genetically engineered and purified using an enzyme process that Perkin-Elmer Cetus says removes unwanted thermostable nucleases. The company says further that studies comparing AmpliTaq with native *Taq* DNA polymerase show that the thermostability and specificity of the recombinant enzyme is equivalent to that of the native form in the PCR process. AmpliTaq DNA polymerase is available separately in 250-unit, 0.05 ml microtubes, or as part of Perkin-Elmer Cetus' GeneAmp DNA amplification reagent kit. The company says researchers who are currently using native *Taq* DNA polymerase can switch to AmpliTaq without modifying their protocols.

Gels and more



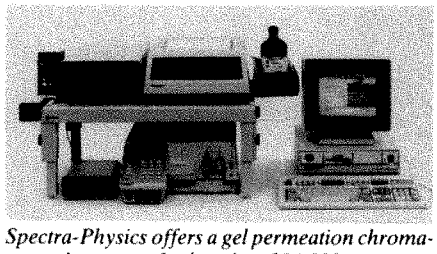
The new model 270A **analytical capillary electrophoresis** system from Applied Biosystems couples the separation power of electrophoresis with microprocessor-controlled instrumentation *(Reader Service No. 112)*. The company says the system makes the fast analysis of a wide variety of molecules routine and minimizes the pre-run preparation time traditionally required by standard electrophoretic protocols. Unlike traditional gel methods, the model 270A automates the electrophoretic separation of molecules in free solution within small-bore capillary tubes, without a gel matrix or denaturant. The entire procedure is automated by an integral, menu-driven system controller.

Applied Biosystems brings analytical capillary electrophoresis to the lab with the model 270A.

Sample loss is virtually eliminated due to the small amount of sample required for analysis, says ABI, and the overall reagent and buffer consumption is extremely low because a small-bore capillary is used.

Bio-Rad has recently released an updated version of its Protean II multi-cell **two-dimensional gel electrophoresis** apparatus *(Reader Service No. 113)*. The improved system comes with a more efficient cooling system that permits higher power settings with minimal diffusion. The gels are first attached to the three central cooling cores of the multi-cell, for uniform heat removal. Two

Results obtained using Bio-Rad's Protean II multi-cell 2D gel electrophoresis setup.

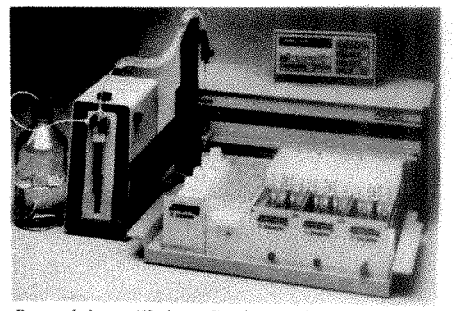


aluminium cooling coils coated with an electrically non-conductive material that exhibits high thermal conductivity are then placed in the lower buffer chamber to chill the second dimension running buffer. The gels are run submerged in the chilled running buffer for optimal heat dissipation. Two new detergents that eliminate equilibration and overnight focusing steps — CHAPS and NONIDET P-40 — are available for use with the system, which comes complete with a step-by-step protcol manual.

Amersham International now offers its Hyperfilm-MP and Hyperfilm- β max high-performance **autoradiography films** in rolls of 20 cm × 25 m *(Reader Service No. 114)*. The larger films are designed for applications which require longer pieces of film than the sizes currently available in sheets, such as DNA sequencing, where users are frequently forced to splice two pieces of film together. For applications such as whole body autoradiography and thin-layer chromatography which require less than one conventional sheet of film, the rolls are more economical. Amersham's Hyperfilm-β max roll film is intended for high-speed, high-resolution direct autoradiography of compounds labelled with ^{14}C, ^{35}S or ^{125}I. The Hyperfilm-MP film is for use with ^{3}H, ^{14}C, ^{32}P or ^{125}I, and can be used with intensifying screens or fluorography.

Molecular Dynamics says its new HRDI Autophoresis 1000A instrument will do for electrophoresis what the telescope did for astronomy *(Reader Service No. 115)*. The company's astronomical claims centre on the high-resolution dynamic imaging (HRDI) properties of the instrument, that allow the detection of bands in electrophoresis gels in real time, without staining. The Autophoresis system not only eliminates gel staining steps and autoradiography, but also allows the user to determine when the compounds of interest are sufficiently separated. Because diffusion is virtually eliminated, Molecular Dynamics says smaller compounds — such as peptides and other molecules which either diffuse rapidly or do not stain well — can be detected. The HRDI optical technique is related to the phase contrast imaging used in microscopy. The gel is illuminated by a HeNe laser light source which projects the image of the gel onto a screen. Portions of the gel which do not contain sample bands appear as dark areas on the screen because light which passes straight through the gel is absorbed by a mask. Bands in the sample bend the light so that it bypasses the mask and is focused on the viewing screen.

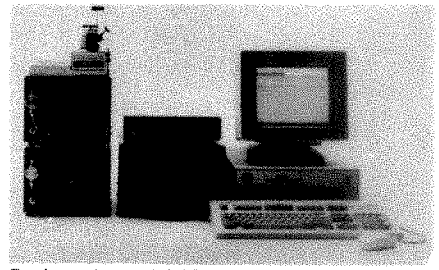
Separation and analysis



The GPC System for **gel permeation chromatography** from Spectra-Physics

Spectra-Physics offers a gel permeation chromatography system for less than $14,000.

includes modular LC hardware, comprehensive software and a selection of columns *(Reader Service No. 116)*. The system consists of two parts: the chromatography hardware including a pump, detector and column oven which the company says is capable of delivering performance repeatability in the one per cent range; and the multi-tasking software which runs on either a Spectra-Physics WINner+ or a ChromStation/2 workstation/integrator. The GPC sofware performs standard operations, collects and stores raw data, calculates molecular weight distribution, plots raw chromatograms, and calibrates using narrow range, broad range or universal standards. Time/area slices or complete reports can be stored automatically, and reports can be customized to fit specific requirements. Once the data are stored, annotated replots of original chromatograms can be produced with drawn-in baseline. The complete hardware system costs $11,300 (US) and the accompanying sofware, $1,250 (US).

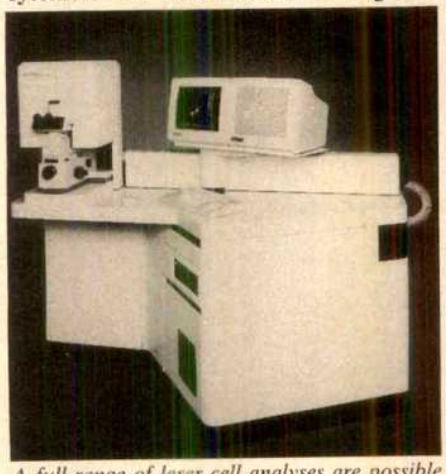


Gilson Medical Electronics has a **sample preparation system** that both cleans a sample automatically and injects the prepared sample into an on-line HPLC system without supervision — the

Busy labs will benefit from Gilson Medical Electronics' ASPEC system.

ASPEC system *(Reader Service No. 117)*. Gilson says the ASPEC system is compatible with most standard 100-mg and 500-mg disposable extraction columns and can process up to 108 complex samples. ASPEC can be used automatically to perform extraction, elution and concentration steps, or for liquid handling operations such as transfers and dilutions. The software is flexible so that operators may select the proper volume and flow rate of each solvent at each extraction step, or program a unique operational sequence. Applications of the ASPEC system include liquid-solid extractions of hormones and drugs in biological fluids, nucleic acids and lipids in tissue/cell extracts, and pesticides in soil and water.

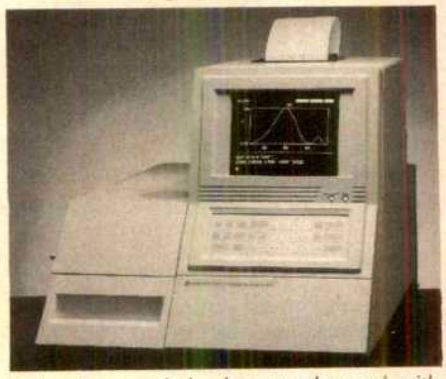
The model 338 **gradient liquid chromatograph** from Beckman Instruments links reliable pumps with programmable UV-visible detectors and provides single-point instrument control *(Reader Service No. 118)*. The system's model 110B pump flow rate range of 0.01–10 ml min^{-1} can be increased to 28 ml min^{-1} with the addition of preparative pumpheads, so that only one system is needed for analytical, high-



Beckman's model 338 gradient liquid chromatograph.

speed and semipreparative chromatography. The variable wavelength Beckman UV-visible 166 detector offers sensitivity down to 0.001 AUFS with low refractive index response and stable baselines, says the company. Results can be optimized automatically through the built-in time programming of absorbance range, wavelength and auto zero. The model 338 system's controller is a NEC lap-top computer, which is linked through an analogue interface to the pump and digitally to the detector module. For more powerful data handling, the system can be used with a desktop PC running Beckman's System Gold software.

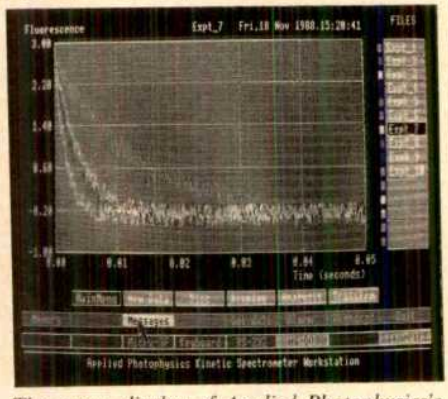
A look inside



Meridian Instruments has recently introduced its ACAS 570 **interactive laser cytometer** for adherent cell sorting and

A full range of laser cell analyses are possible using Meridian's ACAS 570.

quantitative fluorescence analysis *(Reader Service No. 119)*. A focused laser spot provides the capability to use interactive methods, as well as to perform automated quantitative fluorescence imaging and analysis, confocal microscopy, and the measurement of intracellular ions such as calcium and *p*H. Meridian's instrument can be used for optical sectioning, intercellular communication studies, the real-time measurement of cellular dynamics, and the isolation of mutant or transfected cells for propagation or analysis using a unique patented process called "cookie cutter". The ACAS 570 uses an argon ion laser and dual photometric detection system for single or simultaneous dual parameter or ratio measurements on single cells or entire cell populations. Meridian says the system provides optimal sensitivity and quantitation of fluorescence measurements with minimal photobleaching.



Hitachi Instruments has a new **intracellular calcium measurement system** designed for use with Quin, Fura or Indo dyes — the model F-2000 *(Reader Service No. 120)*. A sample introduction system combined with report generation for both tabulated and graphical data provide a

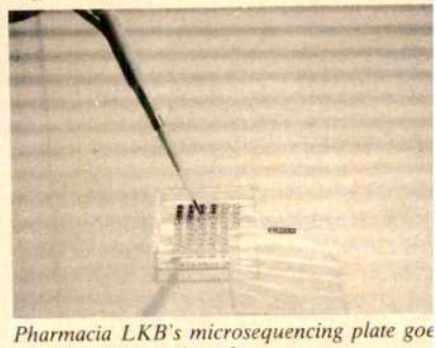
Quin, Fura or Indo dyes can be used with Hitachi's new calcium measurement system.

complete package for the application. The F-2000 features a wavelength slew rate of 200 nm s^{-1} so that a maximum number of data points can be measured during the analysis. Hitachi says the horizontal beam geometry provides a four-fold increase in sensitivity and allows samples of 0.6 ml to be measured routinely in a standard 1 cm cuvette.

Applied Photophysics will be launching two new **spectrometry instruments** at the San Francisco meeting *(Reader Service No. 121)*. The company's model SF.17MV microvolume biocompatible stopped-flow spectrofluorimeter requires just 100 µl of each reactant to prime the sample flow circuit. Comprehensive absorption and fluorescence capabilities, facilities for anaerobic and large-ratio mixing, and a high-performance 32-bit RISC-processor spectrometer workstation

The screen display of Applied Photophysics's stopped-flow spectrofluorimeter.

are provided as standard. Applied Photophysics' model RX.1000 rapid mixing spectrometer accessory can be fitted to any absorbance or fluorescence spectrometer that has a regular 1-cm cuvette holder. The company says the accessory can reduce the shortest half-life measurable on a spectrometer from minutes down to less than one second. Designed to satisfy the users of precious and sensitive chemical and biological samples, the accessory also features an anaerobic capability and large-ratio mixing, and offers comprehensive thermostatting facilities.



Enzymes, etc.

The radiochemicals division of ICN Biomedicals, Inc. has expanded its series of ^{125}I-labelled immunoglobulins with the addition of **goat anti-mouse IgM ^{125}I** *(Reader Service No. 122)*. The antibodies are prepared by immunizing the appropriate host with a purified immunoglobulin from normal serum. The hosts are bled, and the antisera is pooled and then affinity-purified to ensure species specificity. The purified antibodies are then labelled by a mild chloramine-T method and further purified by HPLC. Each batch is tested by measuring its binding to the appropriate immunoglobulin.

Seikagaku America offers a host of products for **cell culture** and manipulation, including enzymes for mucopolysaccharide lysis, cell wall lysis, glycosidases, reverse transcriptase, two inhibitors of myosin light chain kinase and protein kinase activators *(Reader Service No. 123)*. The company's Cellmatrix medium is a collagen gel for culturing cells and tissue. Seikagaku says Cellmatrix is superior to rat-tail collagen because it forms gels more rapidly and reproducibly yields higher strength gels. The medium is useful not only for coating tissue culture surfaces, but for collagen gel matrix culture. Cells can be grown inside the gels to mimic three-dimensional growth *in vivo*.

Pipettes and plates

Pharmacia LKB offers a **microplate for DNA sequencing** which will allow researchers to perform all of the sequencing reactions in a handy sample holder, with no need for tubes and racks *(Reader Service No. 124)*. The company's microsample plate is specifically designed for Sanger reactions: each of its 60 wells accommodates 15 µl and reagents can be added directly to the mixture. The new DNA strand is separated by simply floating the plate on the surface of boiling

Pharmacia LKB's microsequencing plate goes from bench, to bath, to freezer.

water. No evaporation of sample is required. After the gels are loaded, the sample holder can be covered with the lid provided and placed in the freezer.

Eppendorf has a **pipette** for dispensing solutions directly from tall bottles *(Reader Service No. 125)*. The company's Multipipette can now be coupled with its Combilong adaptor to reach into the depths of large bottles. The Combilong consists of an aspirating tube and chamber which has to be filled with solution. The liquid level in the chamber remains constant: the Combitip of the Multipipette takes the liquid directly from the reservoir. The 30-cm long Combilong can be shortened to any length.

These notes are compiled by Carol Ezzell from information provided by the manufacturers. To obtain further details about these products, use the reader service card bound inside the journal. Prices quoted are sometimes nominal, and apply only within the country indicated.

ANNOUNCING AN IMPORTANT EVENT IN SCIENCE PUBLISHING!

THE MACMILLAN MOLECULAR BIOLOGY SERIES

General Editor: Dr C J Skidmore, University of Reading

MACMILLAN MOLECULAR BIOLOGY

Genetic Elements in *Escherichia coli*

NEW

by Dr Peter Smith-Keary

Written for students of molecular genetics and molecular biology, the first volume in the series sets the scene by introducing aspects that provide the scientific background for the major technical advances of genetic engineering. Central topics such as replication, mapping, mutation, transposition and both general and site specific recombination are fully documented.

PB *0333 442687* **£9.95** **HC** *0333 442679* **£25.00**

Organelles

NEW

by Dr Mark Carroll

Aimed at second and third year undergraduate students following courses in biochemistry and cell biology, Organelles draws together the latest developments in our understanding of the ultrastructure and function of cell components. Each major cell organelle is the subject of one complete chapter, which ends with self-study questions to focus the reader on central concepts and principles. Throughout the book there are numerous micrographs and line illustrations.

PB *0333 44244X* **£9.95** **HC** *0333 442431* **£25.00** *(February 1989)*

Forthcoming titles include:

What is a Gene? by Dr C J Skidmore
Protein Biosynthesis by Dr R Jagus
The Molecules of the Cytoskeleton by Dr L Amos and Dr W B Amos

Postdoctoral Associate Positions Plant Molecular Biology

University of Minnesota

Postdoctoral associate positions are available for Ph.D. graduates who wish to participate in an interdisciplinary effort to study the molecular biology of plants. Faculty involved are from the Departments of Agronomy and Plant Genetics (B.G. Gengenbach, R.L. Phillips, D.A. Somers), Biochemistry (A. Das. J.L. Schottel), Botany (J. Berman, J.S. Gantt, N. Olszewski, I. Rubenstein), Genetics and Cell Biology (P.A. Lefebvre, R. Pruitt, C. Silflow, D.P. Snustad), Horticultural Science and Landscape Architecture (M.L. Brenner, A. Smith), and Plant Pathology (R. Brambl). Current areas of interlaboratory research include: floral induction and development, kernel development, organelle biogenesis, gene expression, chromosome structure, and gene transfer.

Salary is commensurate with experience. Applicants should send a curriculum vitae, a brief statement of research interest, and three letters of recommendation to: **Dr. Burle G. Gengenbach, Director, Plant Molecular Genetics Institute, 250 BioScience Center, 1445 Gortner Ave., University of Minnesota, St. Paul, MN 55108–1095, (Telephone: 612-625-6282).** Additional information can be obtained from the Director or any member of the faculty. Applications should be submitted in a complete form by April 30 1989.

The University of Minnesota is an Equal Opportunity Educator and Employer and specifically invites and encourages applications from women and minorities. (NW3180)A

POSTDOCTORAL POSITIONS

are available to work on the molecular biology of adrenergic receptors: Cloning, expression, gene structure, site-directed mutagenesis. Applicants should have a strong background in recombinant DNA technology. Send curriculum vitae and two to three letters of reference to:

Dr. Robert J. Lefkowitz and Dr. Marc G. Caron
Howard Huges Medical Institute
Box 3821
Department of Medicine
Duke University Medical Center
Durham, North California USA 27710
(NW3169)A

ASSISTANT PROFESSORS

CELL PHYSIOLOGY AND EVOLUTIONARY BIOLOGY

The Department of Zoology, University of Tennessee, Knoxville invites applications for tenure-track positions at the ASSISTANT PROFESSOR level. We are seeking a Cell Physiologist with preference given to candidates with expertise in membrane or sensory physiology, or signal transduction, and a Vertebrate Evolutionary Biologist demonstrating a strong research emphasis on morphology, ecology, or ethology. Ph.D. or equivalent and postdoctoral experience required. The successful applicants will be expected to maintian active and funded research programs, teach at undergraduate and graduate levels, and direct undergraduate and graduate research. A course in Comparative Vertebrate Biology will be taught by the Vertebrate Evolutionary Biologist.

Send Curriculum Vitae, brief statements of research interests and teaching experience, reprints of recent publications, and three letters of recommendation to: **Physiology *or* Evolution Search Committee, Department of Zoology, University of Tennessee, Knoxville, TN 39776-0810.** Review of applications will begin 20 February 1989.

UTK is an EEO/AA/Title IX, Section 504 Employer. (NW3220)A

LEAD SCIENTIST

Atherosclerosis Research

For more than a century, scientists at ELI LILLY AND COMPANY have developed innovative, high quality pharmaceutical products. In 1988, Lilly invested over $500 million in research-and-development programs. More than 3,000 scientists at the company's Lilly Research Laboratories are pursuing creative research programs that involve many important health care needs.

To further build its research capabilities, Lilly is seeking an accomplished scientist to lead an atherosclerosis program. This individual will establish a preclinical group of Senior Scientists whose mission will be exploratory research and discovery of drugs to treat atherosclerosis and related vascular disorders, and should have the following qualifications:

- Self-motivation, vision, and the ability to conceptualize, focus, and organize a basic research and drug-discovery program with particular emphasis on biology of the vascular wall.
- Either Ph.D. or M.D. degree, with a minimum of seven years academic or industrial experience, and an indepth understanding of the mechanisms underlying the atherosclerotic process.
- An established research record in the area of atherosclerosis and a national scientific reputation.

In addition, this scientist must have the leadership capabilities needed—analytical, communication, interpersonal, and organizational skills—to build a research program. The successful candidate will have an opportunity to recruit Senior Scientists in the process of building the program.

Eli Lilly and Company is committed to scientific excellence. Lilly provides a stimulating professional atmosphere with many opportunities for collaborative, multidisciplinary research. The company offers an attractive total compensation program. Entry level and salary will be based upon the candidate's experience.

For prompt consideration, please forward your *curriculum vitae* to:

John W. Crooks, Manager
Ph.D. Recruitment (ASR)2
Eli Lilly and Company
Lilly Corporate Center
Indianapolis, Indiana 46285

Lilly

Equal Opportunity Employer

(NW3216)A

UBC

The University of British Columbia

FACULTY OF SCIENCE DEAN

Outstanding candidates are sought for the position of Dean of the Faculty of Science. The new Dean will take office July 1, 1989 or as soon thereafter as possible. The Faculty comprises eleven departments that offer B.Sc., M.Sc. and Ph.D. programs. The B.Sc. can also be earned in selected departments in the Faculties of Arts and of Medicine. There are more than 300 full-time faculty members.

The successful candidate will be a scholar recognized internationally in a field of research that enhances the Faculty. He or she will provide dynamic leadership within the Faculty and play a constructive part in the University's general academic leadership. The Dean will have proven administrative ability and will be dedicated to excellence in teaching.

Applications and nominations should be directed to **Dr. Daniel R. Birch, Vice President (Academic) and Provost, The University of British Columbia, 6328 Memorial Road, Vancouver, B.C. V6T 2B3, no later than March 31, 1989,** and must include a curriculum vitae, a list of publications and the names of at least three referees.

In accordance with Canadian Immigration requirements priority will be given to Canadian citizens and permanent residents of Canada. The University of British Columbia offers equal opportunity for employment to qualified female and male applicants.

(NW3211)A

BIOTECHNOLOGY

CODON is a research and manufacturing, product-oriented biotechnology corporation specializing in the development and manufacture of high value-added recombinant protein products. We are rapidly expanding, and focused at finding novel solutions to today's most complex medical and veterinary conditions.

Employment opportunities at Codon cover a wide range of disciplines, including protein chemistry, molecular biology, immunology, tissue culture, process development, fermentation, biochemical engineering and quality assurance. Most positions require a minimum of a baccalaureate degree and laboratory experience in the above or allied fields.

To find out how you may fit into this exciting, intellectually stimulating environment, please send your resume and letter outlining area of interest to: **CODON, Human Resources Dept. 572, 213 E. Grand Ave., South San Francisco, CA 94080.** Equal Opportunity Employer

Our location, just south of San Francisco, California, places us in one of the major biotechnology centers in the country and affords close contact with prime educational institutions such as Stanford University, The University of California, San Francisco, and The University of California, Berkeley.

CODON

(NW3186)A

UNIVERSITY OF LIVERPOOL

Department of Physiology

Postdoctoral Senior Research Assistant

A three year post is available to investigate a second messenger system recently discovered to operate in the brain in association with excitatory amino acid receptors of the NMDA type (see Nature 336, 385-388, 1988). The work will be multidisciplinary in approach and will be carried out on isolated CNS cells and brain slices. Applications from individuals whose primary expertise is in electrophysiology, pharmacology, biochemistry or cell biology are all welcome.

The project is funded by the MRC at an initial salary within the range £9,865-£11,680 per annum. Informal enquiries may be made to Dr. John Garthwaite. Tel. 051-794 5329.

Applications, together with the names of 3 referees, should be received as soon as possible by **The Director of Staffing Services (AS). The University, P.O. Box 147, Liverpool, L69 3BX,** from whom further particulars may be obtained. Quote ref. RV/238/N.

An Equal Opportunity Employer (8179)A

ROYAL POSTGRADUATE MEDICAL SCHOOL (University of London) DEPARTMENT OF CLINICAL PHARMACOLOGY SENIOR RESEARCH OFFICER In Cellular Biochemistry/Immunology

Applications are invited from post-doctoral scientists to work on the signal-transduction system involved in IgE-mediated response of macrophages. The events appear complex, and involve the CD23 antigen which fulfils a receptor role for both low MWt B Cell Growth Factor and IgE. Funding is for 3 years from the Asthma Research Council.

Salary will be on the scale: £9865-£15720 plus £1650 London allowance a year.

Application forms and further particulars are available from the **Personnel Officer, Royal Postgraduate School, 150 Ducane Road, London W12 0NN** (tel: 01-740 3204) quoting ref: AEW3.

Closing Date: 9th February 1989. (8168)A

POSTDOCTORAL POSITIONS/MOLECULAR BIOLOGY

Positions available immediately for independent and highly-motivated molecular biologists to join a group of immunobiologists studying molecular and cell biological aspects of T cell activation, including transmembrane signalling and the role of receptors, protein kinases and G proteins. Experience in molecular biology techniques (library construction, gene cloning and sequencing, mRNA expression and cDNA transfection) is essential. Well-qualified candidates with keen interest in this area should apply to:

Dr. Amnon Altman
Research Institute of Scripps Clinic
10666 North Torrey Pines Road/IMM3
La Jolla, California 92037
(619) 554-8602

An Affirmative Action/Equal Opportunity Employer (NW3187)A

FACULTY, MOLECULAR VIROLOGY

The Department of Ophthalmology of Washington University School of Medicine invites applicants for a position at the Assistant or Associate Professor level to join a dynamic core research faculty with interests in infectious and inflammatory diseases that may affect the eye. The successful Ph.D. or M.D. candidate will have an active research program in molecular virology, experience with one or more ocular pathogens (herpesviruses, adenovirus, HIV), and an interest in combining basic scientific methodology to the study of ocular disease processes. Previous specific experience in ophthalmic research is not required. Start-up funds, laboratory and a competitive salary are available. Submit curriculum vitae and three letters of reference to:

Henry J. Kaplan, M.D.
Chairman, Department of Ophthalmology
Washington University School of Medicine, Box 8096
660 South Euclid Avenue
St. Louis, MO 63110 (NW3182)A

FACULTY POSITIONS

SLOAN-KETTERING INSTITUTE

CELL BIOLOGY AND GENETICS PROGRAM

The Sloan-Kettering Institute invites applications for several tenure-track junior and senior faculty positions in the Cell Biology and Genetics Program. This research program is one of four in the Institute, and is undergoing a major expansion in research at the molecular level on the areas of positive and negative growth control, differentiation, cell structure, intercellular recognition, and morphogenic pattern formation. The Cell Biology Program and the Molecular Biology Program at the Sloan-Kettering Institute are jointly relocating to a new research building which also houses advanced facilities for protein and nucleic acid microchemistry, transgenic mice, and automated mammalian cell micromanipulation. The faculty members of the Cell Biology and Genetics Program are also affiliated as faculty with the Cell Biology Graduate Program at Cornell University Medical School. The positions offered are highly competitive with regard to start-up funds, laboratory space, salary and housing.

Eligible candidates should have a doctoral degree, post-doctoral experience and demonstrate potential and ability to develop an independent, imaginative research program. Formal applications are invited from junior as well as established investigators. Applications should include a curriculum vitae, a list of publications, a summary of research activities and research plan, and the names of three or more references. Applications should be addressed to: **Dr. Joan Massague, Cell Biology and Genetics Program, Sloan-Kettering Institute, 1275 York Avenue, New York, NY 10021.**

(NW3199)A

STRUCTURAL BIOCHEMISTRY FACULTY POSITION UCLA

The Department of Chemistry and Biochemistry and the Molecular Biology Institute have a **TENURE-TRACK OPENING** in structural biochemistry. The position probably will be filled at the assistant professor level, but applications for a more senior position will also be considered. We are seeking a candidate who will establish a strong and innovative research program in the area of biological structure, although highly exceptional applications in other areas will be considered. Teaching responsibilities will include undergraduate biochemistry and participation in graduate courses appropriate to the appointee's interests. Candidates should submit curriculum vitae and statement of research plans, and should have three letters of recommendation sent to:

Dr. David Eisenberg
Department of Chemistry & Biochemistry
University of California
Los Angeles, CA 90024–1569
by April 15, 1989

The University of California is an Equal Opportunity/Affirmative Action Employer, and encourages applications from women and minority candidates. (NW3224)A

Animal Physiology/ Molecular Biology/ Tissue Culture

STAFF SCIENTISTS

TKT Inc. is a newly established biotechnology company dedicated to the development of innovative technologies for the treatment of human disease, emphasizing gene therapy. We are seeking Ph.D. level scientists to conduct research on animal physiology, mammalian gene expression, and regulation of cell growth. Experience in one of the following areas is essential:

Animal physiology: development of animal model systems; mammalian endocrinology and metabolism. Experience in small animal surgery is essential.

Molecular biology: recombinant DNA technology; structure and function of mammalian genes.

Tissue culture: establishment, maintenance and transfection of mammalian cell lines.

Excellent location in Cambridge, Massachusetts, competitive salaries and benefits, and an opportunity for equity participation in a challenging environment. Send resume and list of three references to: **TKT Inc., Suite 154, 295 Cambridge St., Boston, MA 02114.**

(NW3217)A

Oregon State University

Assistant or Associate Professor Laboratory for Nitrogen Fixation Research Oregan State University

A 12-month tenure-track position is available at the rank of Assistant or Associate Professor with responsibility to lead a vigorous research program on the molecular biology and physiology of symbiotic nitrogen fixation and to teach a graduate course in the area of expertise. Requirements include a Ph.D. degree, postdoctoral experience, a strong background in biochemistry or plant physiology and in molecular biology, and an established record of research productivity. Applicants should submit a curriculum vitae, statement of research and teaching interests, list and samples of publications, and names of four references to: **Search Committee for Nitrogen Fixation Position, Department of Botany and Plant Pathology, Oregon State University, Cordley Hall 2082, Corvallis, OR 97331-2902.** Closing date: March 31, 1989. Position available: September 1, 1989. OSU is an AA/EOE and complies with Section 504 of the Rehabilitation Act of 1973. OSU has a policy of being responsive to the needs of dual-career couples. (NW3214)A

RESEARCH ASSOCIATE

MOLECULAR BIOLOGY OF CYTOKINES

Laboratory of Medical Biochemistry
The Rockefeller University

Independently conduct molecular and genetic research in ongoing projects to characterize macrophage-derived inflammatory mediators and immunomodulatory monokines. The highly motivated scientist we seek will have demonstrated competence in applied molecular biology including cDNA cloning and expression, gene regulation, PCR applications and hybridization techniques. Must demonstrate competence to coordinate all molecular biological approaches in the efforts of a multidisciplinary team exploring the biochemistry, cell biology, immunology, in vivo functions and clinical importance of several newly-discovered cytokines.

Salary commensurate with research experience and leadership abilities. The Rockefeller University is an Equal Opportunity/Affirmative Action Employer and invites applications from all qualified individuals. Please contact:

Anthony Cerami, Ph.D.
Professor and Head,
Laboratory of Medical Biochemistry
The Rockefeller University
1230 York Avenue
New York, NY 10021

THE ROCKEFELLER UNIVERSITY

(NW3204)A

Cell Biologist
Biophysicist
Structural Biologist
Molecular Biologist

The Pennsylvania Muscle Institute and the University of Pennsylvania School of Medicine seek outstanding candidates for two tenure track positions in the area of fundamental cardiovascular or motility research. One position will be in the field of molecular genetics of contractile proteins.

The other position is in the broad area of cell biology, biophysics and/or structural biology of muscle. These positions are primarily aimed at, but not restricted to, the Assistant Professor level. Appointment will be made in the department appropriate to academic interest.

Applicants should send CV and research statements and the names of three references to: **Yale E. Goldman, M.D., Ph.D., Director of Pennsylvania Muscle Institute, School of Medicine, University of Pennsylvania, Philadelphia, PA 19104-6085.**

Equal Opportunity/Affirmative Action Employer. (NW3052)A

Career Opportunities in Chemical Information

Molecular Biology

General Biochemistry
(German, French, Japanese, Russian)

Analytical Biochemistry
(German, French, Japanese, Russian)

Pharmaceutical Chemistry
(German, French, Japanese, Russian)

Medicinal Chemistry
(German, French, Japanese, Russian)

The continuing growth of CAS's information services has created openings for full-time chemical scientists to be involved in the extraction and analysis of chemical information. An advanced degree in one of the scientific areas listed above plus skills with one of the languages listed is required. However, you do not need prior work experience in this activity.

CAS is located in Columbus, Ohio, a growing and dynamic metropolitan area with excellent housing, cultural, recreational and transportation facilities. Our modern offices, situated in a campus-like setting, provide a professional and comfortable working environment.

CAS provides a complete benefits package, which includes flexible working hours, tuition reimbursement, generous vacation and a range of employer-paid insurance programs.

Applicants must be located in and be eligible to work in the U.S. If you meet our specific qualifications, you can apply by sending your resume (indicating position desired) and salary requirements to:

Chemical Abstracts Service
Employment Department-B
P.O. Box 3012

A Division of the American Chemical Society

An Equal Opportunity Employer M/F

UNIVERSITY OF LIVERPOOL
Interdisciplinary Research Centre for Surface Science

Experimental Officer/Senior Experimental Officer

Applications are invited for the position of Experimental Officer/Senior Experimental Officer in the Interdisciplinary Research Centre in Surface Science. The successful applicant will be attached to the Interfaces and Semiconductor Surface Chemistry project of the IRC.

The appointee will be responsible for the support of existing equipment and the installation and development of new equipment. There will also be opportunities to take part in the planning and execution of the research programme. Applicants should have a degree or equivalent qualification. Experience of surface science instrumentation would be an advantage.

This is a permanent position. Initial salary on the scale for Experimental Officer £8,675-£13,365 per annum or Senior Experimental Officer £12,145-£15,720. Informal enquiries may be made to Dr. P. Weightman. Applications, including c.v. and the names of three referees, should be received not later than 17 February 1989, by **The Director of Staffing Services (AS), The University, P.O. Box 147, Liverpool, L69,** from whom further particulars may be obtained. Quote ref. RV/243/N.

An Equal Opportunity Employer (8178)A

UNITED MEDICAL AND DENTAL SCHOOLS
LECUTRESHIP IN THE DIVISION OF PHARMACOLOGY & TOXICOLOGY

Applications are invited for a Lecturer in the Division of Pharmacology and Toxicology. The post will be for three years in the first instance with a possible extension to five years.

Teaching commitments will be primarily to pre-clinical medical students and there may be some administrative duties. The lecturer will be expected to pursue research in pharmacology. No particular line of research is required but the Division has particular interests in psychopharmacology (Guys Campus), electrophysiology of muscle, central transmitters and retinal degenerative diseases (St Thomas's Campus). The new lecturer will be based at the campus most appropriate for his/her area of research.

Intending applicants should have a first degree in medicine, pharmacology or related subject, a PhD or MD and must have the ability to present lecturers, communications etc in a clear and interesting way.

Further information may be obtained from Professor M J Neal, Division of Pharmacological Sciences, UMDS, St Thomas's Campus on 01-928 9292 Ext 2080. Salary will be on the lecturer scale Grade 'A' £9,260-£14,500 or Grade 'B' £15,105-£19,310 plus London Weighting Allowance, depending on age and qualifications.

Applications, with full curriculum vitae (six copies) and the names of two referees, should be sent to the **Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH** quoting reference STH/PHAR 283 by 15 January 1989. (8180)A

CHAIRPERSON

DEPARTMENT OF STOMATOLOGY
UNIVERSITY OF CALIFORNIA, SAN FRANCISCO
SCHOOL OF DENTISTRY

Full-time position as Chairperson of the Department of Stomatology which includes programs in oral biology, oral medicine, oral pathology, periodontology, and oral radiology. Responsibilities include providing academic and administrative leadership in research, teaching, patient care and community and university service for undergraduates, predoctoral and postdoctoral students, and faculty.

Demonstrated administrative experience and academic qualifications (D.D.S., M.D., Ph.D. or equivalent degree) for a senior professorial rank are required. Salary commensurate with qualifications and experience. Applications from women and minorities are encouraged. The University of California, San Francisco is an equal opportunity, affirmative action employer.

Please send curriculum vitae and the names of three individuals familiar with your work to **Dr Leonard B. Kaban, Chair, Search Committee, in care of: Office of the Dean, School of Dentistry, Box 0430, UCSF, San Francisco, California 94143.**

Applications should be submitted by February 28, 1989.

(NW3171)A

ERATO

Exploratory Research for Advanced Technology

RESEARCH DEVELOPMENT CORPORATION OF JAPAN

RESEARCH ENGINEERS AND SCIENTISTS: You are invited to COME TO JAPAN to do research at the forefront of basic science and engineering. ERATO, a program fully funded and administered by the Research Development Corporation of Japan (JRDC), a statutory corporation of the Japanese government, has been inviting non-Japanese researchers to Japan since 1981. ERATO is now seeking researchers for the following projects:

SAKAKI QUANTUM WAVE (1988-1993) – **Solid physicists, solid state chemists,** and **semiconductor engineers** will research the fabrication and behavior of quantum wells and wires, structures with features smaller than the electron's mean free path.
Project Director: Professor Hiroyuki Sakaki, Research Center for Advanced Science and Technology, University of Tokyo

MASUHARA MICRO PHOTOCONVERSION (1988-1933) – **Spectroscopists, applied physicists, electronic engineers, physical chemists, catalysis chemists, polymer chemists, synthetic organic chemists, materials scientists,** and **bioengineers** will research the use of lasers to drive, measure, and control pico-second chemical reactions in micrometer-size volumes.
Project Director: Professor Hiroshi Masuhara, Kyoto Institute of Technology

MIZUTANI PLANT ECOCHEMICALS (1988-1993) – **Natural products chemists, organic chemists, analytical chemists, biochemists, molecular biologists, genetic engineers, botanists, plant physiologists, microbiologists, entomologists, zoologists,** and **ecologists** will research the ways in which plants use chemical substances to regulate surrounding plants and animals.
Project Director: Professor Junya Mizutani, Hokkaido University, Sapporo

NISHIZAWA TERAHERTZ (1987-1992) – **Solid state physicists, electron physicists, electronic engineers, solid state chemists,** and **communications engineers** are researching the fabrication, behavior, and measurement of semiconductor devices for operation at terahertz frequencies.
Project Director: Professor Jun'ichi Nishizawa, Tohoku University and Semiconductor Research Institute, Sendai

FURUSAWA MORPHOGENE (1987-1992) – **Protein chemists** are invited to join embryologists, developmental biologists, and other protein chemists in researching the identification and expression of gene groups which control morphogenesis with special focus on the early differentiation and development of germ cells and on the fundamental processes of gastrulation.
Project Director: Dr. Mitsuru Furusawa, Deputy General Manager, Dai-ichi Seiyaku Research Institute, Tokyo

KUNITAKE MOLECULAR ARCHITECTURE (1987-1992) – **Synthetic chemists, polymer chemists, surface chemists,** and **solid state physicists** are researching the architecture and function of self-assembling organic systems – their molecular design and synthesis, the introduction of function, and the creation of three-dimensional architectures.
Project Director: Professor Toyoki Kunitake, Kyushu University, Fukuoka

HOTANI MOLECULAR DYNAMICS ASSEMBLY (1986-1991) – **Biophysicists, biochemists,** and **molecular and structural biologists** are researching the ways in which supramolecules perform functions such as self-organization, energy conversion, and information processing.
Project Director: Dr. Hirokazu Hotani, Associate Professor, Kyoto University

ERATO RESEARCHERS BENEFIT FROM

Well-funded, multidisciplinary research
Long-term positions – allowing for significant, in-depth research
Industry-competitive salaries
Sharing of patent rights and profits
Assistance for Japanese language learning (ability in Japanese not required)
Cooperative agreements with industry to allow corporate researchers to join

For an evaluation of ERATO, see "JTECH (Japanese Technology Evaluation Program) Report on ERATO," National Science Foundation, Dec. 1988 – available from NTIS, 5285 Port Royal Road, Springfield, Virginia 22161 USA, Telephone (703)487-4826.

Please send your resume and list of publications to ERATO, c/o

CHAIRPERSON

DEPARTMENT OF BIOCHEMISTRY

emple University School of Medicine is seeking an individual with emonstrated administrative skills and an outstanding record of chievement in research and teaching to succeed the present chairan. The candidate should demonstrate a commitment to excellence research, medical education, and graduate training. The departent currently has excellent research and graduate programs, and fective collaborative arrangements with the Fels Institute for Cancer esearch and Molecular Biology and the Thrombosis Center at emple University. As one of the five medical schools in the Philadelhia area, there are excellent opportunities for collaborative ograms with other institutions, the Fox Chase Cancer Center, and veral major pharmaceutical companies in the Delaware Valley and rrounding area.

pplications and nominations together with curriculum vitae may be nt to: **John J. O'Neill, Ph.D., Chair, Search Committee, Department Pharmacology, Temple University School of Medicine, 3400 North road Street, Philadelphia, PA 19140.**

n Equal Opportunity/Affirmative Action Employer. (NW3200)A

PENN STATE

FACULTY POSITION

PROTEIN X-RAY CRYSTALLOGRAPHY

Applications are invited for a tenure-track faculty position at any level in protein x-ray crystallography. The position will be available in either the Department of Chemistry, the Department of Molecular and Cell Biology, or as a joint appointment in these departments or with Penn State's Biotechnology Institute. Applicants, with a Ph.D. degree, should have the background, motivation, and ability to develop vigorous, productive research programs and to be excellent teachers.

Include a detailed curriculum vitae, statement of research interests, and up to three recent reprints, and have three letters of reference sent directly to: **The Search Committee, Department of Chemistry, 152 Davey Laboratory, Box N, University Park, PA 16802.** Deadline for receipt of applications is 15 March 1989, or until a suitable candidate is identified.

Equal Opportunity Employer. Women and minorities encouraged to apply. (NW3166)A

POSTDOCTORAL POSITIONS IN AUDITORY PHYSIOLOGY AND NEUROANATOMY

Institutional Postdoctoral Fellowships are available in the Johns Hopkins Center for Hearing Sciences. Current research areas include: hair cell physiology, stimulus coding and signal processing in the peripheral and central auditory system, neuroanatomy of the cochlear nucleus, cellular biophysics and electrophysiology in cochlear nucleus and psychoacoustic measures of hearing in animals.

Send vita and names of three references to: **Director, Center for Hearing Sciences, The Johns Hopkins University School of Medicine, Baltimore, MD 21205.**

The Johns Hopkins University is an equal opportunity/affirmative action employer. (NW3194)A

POSTDOCTORAL POSITIONS

available to study biology and biochemistry of basic fibroblast growth factor (bFGF). Ongoing projects include regulation of bFGF synthesis and expression, autocrine activities of bFGF, biochemistry of growth factor interaction with extracellular matrix, and characterization of the bFGF receptor. Experience in biochemistry or molecular biology preferred. Send curriculum vitae and names of three references to **Dr. Daniel B. Rifkin or Dr. David Moscatelli, Department of Cell Biology, New York University Medical Center, 550 First Ave., New York, NY 10016.** (NW3178)A

RESEARCH POSITIONS

available immediately for (two) recent PhD's with strong background in molecular biology, recombinant DNA studies, and/or biochemistry. Projects involve studies on regulation of cellular and viral oncogenes and their products in mammary cells. Related areas of research include the expression of HIV genes under hormonal control. Technical help is available. Positions could lead to nontenure track faculty position within 12 months and the candidates will be given opportunity in developing independent research programs. Salary is negotiable. Please submit curriculum vitae and names of three references to: **Professor N. H. Sarkar, Head Laboratory of Molecular Virology, Department of Cell and Molecular Biology, Medical College of Georgia, Augusta, GA 30912-2100.** EOE/AAP. (NW3208)A

POSTDOCTORAL POSITION IN CELLULAR NEUROBIOLOGY

Position available immediately to study physiology and pharmacology of synaptic events in the spinal slice preparation and molecular mechanisms of tachykinin actions. Project involves the use of single-electrode voltage-clamping and whole-cell voltage-clamping with a patch electrode. Send curriculum vitae, statement of research interests, and names of three references to:

Mirjana Randic,
Department of Veterinary Physiology and Pharmacology,
College of Veterinary Medicine,
Iowa State University,
Ames, IA 50010, U.S.A.

Closing Date: March 1, 1989. (NW3193)A

ASSISTANT PROFESSOR

MOLECULAR NEUROBIOLOGY

A tenure-track position is available in a growing interdisciplir neuroscience research program between the Departments of Pec rics and Anatomy. Preference will be given to applicants who h demonstrated expertise in applying molecular biology to the foll ing areas of CNS research: oncology, development, immunolog genetics. The successful applicant will be expected to conduct active research program which complements ongoing resea efforts, to obtain extramural support and to participate in the med school teaching responsibilities of the Department of Anatomy.

Please submit curriculum vitae, statement of research goals, names and addresses of four references to: **Shirley Ann Gilm Ph.D., Professor and Chairman, Department of Anatomy (#5 University of Arkansas for Medical Sciences, 4301 West Markh Little Rock, AR 72205-7199**

The University of Arkansas for Medical Sciences is an Equal Oppo nity/Affirmative Action Employer. (NW3219)

SENIOR STAFF INVESTIGATOR

Applications are invited for a full-time resea position in the Renal Research Program, Departm of Medicine. The position involves research in broad areas of extracellular matrix biology. Applica must have demonstrated strong motivation tow creative research and ability for independent wo Candidates must possess a Ph.D. or M.D. degree a substantial experience in the molecular biology a biochemical aspects of collagen/proteoglyc biosynthesis. Excellent facilities and support available. Please submit curriculum vitae and repri of most recent significant publications to: **Mr. Da Shepherd, CFP-514, Henry Ford Hospital, 2799 W Grand Boulevard, Detroit, MI 48202.** (NW3172)A

UNITED MEDICAL AND DENTAL SCHOO GUY'S CAMPUS — CLOSE TO LONDON BRIDGE

LABORATORY SCIENTIFIC OFFICER or RESEARCH ASSISTANT (pending on experience and qualifications) in Bacteriology, with rel ence to an immunological research project into prevention of colc sation of Oral Streptococci and Anaerobic Bacteria. The appointm is for two years in first instance.

Salary in range: £6,190 + £1,267 London Weighting (LSO) — £13, + £1,650 London Allowance (Research Assistant), according to perience and qualifications.

For further information please contact Miss Lesley Bergmeier (01-4 7600 ext 2965).

Applications, with full curriculum vitae and names of two referees, **Staffing Officer, UMDS, Lambeth Palace Road, London, SE1 7E** quoting Ref: G/IMM/286. (8192)A

UNITED MEDICAL AND DENTAL SCHOOL GUY'S COMPUS — CLOSE TO LONDON BRIDGE

RESEARCH ASSISTANT IN MOLECULAR SCIENCE required for clo ing and sequencing of microbial surface proteins or T cell surfa receptors. Graduate or Postdoctoral scientists may apply if they ha experience in molecular biology or protein chemistry.

Salary, according to qualifications and experience, in range £8,675 £14,500 plus £1,650 London Allowance. Appointment is for thr years.

For further information, please contact Professor Thomas Lehner Dr Charles Kelly — 01-407 7600 ext 2960/2965.

Applications, with full curriculum vitae and names of two referees, **Staffing Officer, UMDS, St Thomas's Campus, Lambeth Palace Roa London SE1 7EH,** quoting Ref: G/IMM/284. (8191)A

NWO

The Laboratory for Space Research, part of the Space Research Organisation of the Netherlands (SRON), has a tenure tracked position for an

astronomer

available to support their work on infrared spectroscopy and submm observations.
SRON is founded within the framework of the Netherlands Organisation for Scientific Research (NWO). The Laboratory is located at the University of Groningen.

The astronomer should be oriented towards theory and interpretation and should also be able to guide observational programmes. The work should be mainly motivated by the data bases already acquired by the Laboratory, and to be obtained in the future: IRAS and the IRAS low Resolution Spectrometer data (special processing is done in Groningen), data obtained with the JCMT at Hawaii and in the future ISO spectrometer data.

The candidate is expected to have close contacts with the data analysis group and with the Kapteyn Astronomical Institute. He will also play an important role in the ISO observations programmes, particulary in spectroscopy.

The salary depends on experience and ranges from ƒ 3.867,— to ƒ 6.908,— a month.

Candidates are invited to apply for this position. Letters, together with three letters of recommendation, should be addressed to the personnel manager, Mrs. W. Lawerman, SRON, Beneluxlaan 21, 3527 HS Utrecht, the Netherlands. Reference number ROG 88/6. More information on the job can be obtained from the Director of the Laboratory, Dr. Th. de Graauw (tel.: 31-50-634074). The closing date for application is march 1, 1989.

(W5790)A

UNIVERSITY OF OXFORD
Departmental Demonstrator in Pharmacology

The Department of Pharmacology wishes to appoint a Demonstrator to teach CNS pharmacology. The person appointed should have the appropriate research experience and would be expected for the first three years to join an existing research group, either in the Department or in the MRC Anatomical Neuropharmacology Unit. Projects available are: neurochemistry and neurophysiology of modulatory mechanisms in the basal ganglia (Dr. S.A. Greenfield) or the pharmacology and chemical neuroanatomy of cerebral cortex, hippocampus, basal ganglia or medullary cardiovascualr centres (MRC Unit).

The salary is on the scale from £8675 to £12150 p.a. according to age and the post is for three years in the first instance. The appointment may be extended for a further maximum period of three years in which case the Demonstrator would be allocated independent research space.

Applicants must have experience in the appropriate techniques in neuroscience (e.g. intracellular recording or neuroanatomy) and should apply by March 1st 1989 to **Professor A.D. Smith, Department of Pharmacology, South Parks Road, Oxford OX1 3QT, from whom further particulars may be obtained. (Tel: 0865- 275162; FAX: 0865-275161).**

THE UNIVERSITY IS AN EQUAL OPPORTUNITY EMPLOYER (8201)A

POSTDOCTORAL/RESEARCH SCIENTIST

Ph.D. in Biochemistry or Biology. To study adipocyte differentiation at the cellular and molecular levels. Work will include purification of cell produced factors influencing differentiation, study of their expression and action during differentiation at the molecular level. Positions available in June and September 1989. Please send curriculum vitae and three letters of references to **Dr. Ginette Serrero, c/o Personnel Office, W. Alton Jones Cell Science Center, 10 Old Barn Road, Lake Placid, NY 12946.**

Please refer to Job No. 88-21. The Cell Science Center is an Equal Opportunity/Affirmative Action Employer. (NW3170)A

ansto

AUSTRALIAN NUCLEAR SCIENCE & TECHNOLOGY ORGANISATION

RESEARCH FELLOW
MATERIALS SCIENCE/ELECTRON MICROSCOPY

Position No. 762

Research Scientist
$A31,003-$A38,045 per annum

Senior Research Scientist
$A39,349-$A45,177 per annum

A vacancy currently exists within the Advanced Materials Program of the Australian Nuclear Science and Technology Organisation (ANSTO) for a research fellowship within the Electron Microscopy Group. The successful applicant will be expected to interact fully with other scientists in the program and will have opportunity to participate in collaborative programs with industry. Current projects include:

- Phase development and crystal chemistry of Synroc, a titanate ceramic for nuclear waste encapsulation.
- Studies of structural changes in minerals and synroc during weathering or hydrothermal dissolution.
- Radiation damage in metamict minerals and neutron irradiated ceramics.
- Advanced ceramics for biomedical and electrical applications e.g. high Tc superconductors, proton conductors etc.
- Remnant life studies of steels.

The fellow will also be encouraged to develop his/her own research projects and/or industrial collaboration, provided such interests fall within the Programs general aims.

The Advanced Materials Program has one JEM 2000 FX TEM fitted with a Gatan TV system and a conventional Si/Li ED spectrometer; and a second JEM 2000 FX fitted with a wide bore pole piece and a thin window detector. Other facilities include a JEOL JSM 6400 SEM, a JEOL JXA 840 analytical SEM, a computer controlled Phillips PW 1050 diffractometer, a Siemens D 500 automatic XRD unit, optical microscopes, a Zeiss quantitative image analysis system, mechanical testing equipment and an extensive ceramics processing laboratory.

The Organisation utilises a salary system based on personal merit for this category of staff. Progression to higher grades is possible as experience, skills, knowledge and personal contributions to the Organisation's programs increase.

Salary depending upon qualifications and experience will be within the above range.

Knowledge, qualifications and Skills
Applications are sought from electron microscopists **and** from materials scientists with experience in analytical TEM techniques. The skills sought include experience with HRTEM, ATEM, image processing, image simulation, materials fabrication, metallurgy, crystal chemistry, mineral dissolution/alteration, structure/property relationships, radiation damage, and electroceramics.

Applicants should have a PhD or equivalent in relevant physical sciences and extensive experience with transmission electron microscopy.

At least two Professional referees should be nominated. It is intended that the skills and experience of the successful applicant will complement those of existing staff.

Employment will be for a term of 3 years, with Australian Government superannuation benefits available.

Contact Officer for further information is Dr K Smith telephone (02) 543 3505 or Fax (02) 543 5097.

Closing date for applications is 17 February, 1989, although applications received after that date may be considered. It is hoped that the successful applicant would begin duties on or before 1/4/89.

Application forms and selection criteria may be obtained by telephoning (02) 543 3064 or writing to the Recruitment Officer, Australian Nuclear Science and Technology Organisation, Private Mail Bag 1, Menai, N.S.W. 2234, Australia, quoting the above position number.

ANSTO IS AN EQUAL OPPORTUNITY EMPLOYER.

SW3175

NEUROBIOLOGIST

Two postdoctoral positions are available immediately in a multidisciplinary laboratory for individuals interested in pursuing studies on the function of astrocytes. One position involves examination of astrocytic responsiveness using a video-based imaging system to monitor changes in intracellular ions via fluorescent probes. The second position involves isolation of pharmacologically-distinct subpopulations of astrocytes and examination of factors released from astrocytes following receptor stimulation. Individuals interested should have a strong background in biochemistry and pharmacology.

Send curriculum vitae to **Dr. Ken D. McCarthy, Department of Pharmacology, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC 27599-7365.**

Equal Opportunity Employer. (NW3212)A

UNIVERSITY OF WARWICK

Senior Technician

The Department of Biological Sciences has a vacancy for a technician to organise and co-ordinate the technical facilities of a section of the Virology Research Group. The person appointed will also be actively involved in research, under the direction of Professor N J Dimmock, on projects which currently range from viral immunology to molecular cloning.

Applications are invited from persons who are suitably qualified and experienced in one or more of these areas and who have an interest in technical administration. The post has prospects for regrading if proposed developments materialize.

Salary on the Technician Grade 5 scale: £8088–£9549 pa.

Application forms from the **Personnel Office, University of Warwick, Coventry CV4 7AL (0203 523685)** quoting Ref No 24/4T/88/14 (please mark clearly on envelope). Closing date for applications 2 February 1989.

AN EQUAL OPPORTUNITIES EMPLOYER (8194)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)
DEPARTMENT OF HAEMATOLOGY
MRC/LRF LEUKAEMIA RESEARCH UNIT

RESEARCH TECHNICIAN required in Leukaemia Cell Biology Laboratory. The work in this laboratory is directed towards immunological control of leukaemia cell growth.

The position includes responsibility for long term storage of blood and bone-marrow in liquid nitrogen, preparation of culture media and reagents, and maintenance of cell lines. General duties will include maintenance of laboratory supplies.

Applicants should have good general laboratory experience, preferably with a haematology/immunology background. For further information please call Dr Julie Adams 743-2030 Ext 3237.

Salary on range £7415-£10148 plus £1267 London Allowance pa.

Application forms and further particulars are available from the **Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road London W12 0NN** (tel: 01-740 3204) quoting reference AFB3.

Closing Date: 7th February 1989 (8169)A

UNITED MEDICAL AND DENTAL SCHOOLS
GUY'S CAMPUS — CLOSE TO LONDON BRIDGE

LABORATORY SCIENTIFIC OFFICER

required to join a team working on DNA sequencing and cloning of microbial proteins and T cell surface receptors. Experience in molecular biology or microbial biochemistry is desirable.

Salary, according to qualifications and experience, in range £6,190 to £12,214 plus £1,267 London Weighting. Appointment is for three years.

Applications, with full curriculum vitae and names of two referees, to **Staffing Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH**, quoting Ref: G/IMM/285. (8193)A

UNIVERSITY OF GLASGOW
Department of Veterinary Pathology
Postdoctoral and Graduate Research Assistants
Retrovirus Vectors and Transgenic Animals

Applications are invited from postdoctoral and graduate molecular biologists for an AFRC funded project aimed at developing retrovirus for the production of transgenic domestic animals.

These positions are available for three years from February 1989 on the 1A Scale for postdoctoral applicants (£11,680 – £15,720) and the 1B scale for graduates (£8,675 – ££11,680).

The successful candidates will join an active group involved in the production of transgenic animals resistant to viral infections and they will be part of a department which has a major interest in the molecular biology of human and animal retroviruses.

Postdoctoral applicants must have an extensive working knowledge of recombinant DNA procedures. Experience of work on the molecular biology of viruses, particularly retroviruses, would be an advantage. Graduate applicants should have a degree in virology, molecular biology, or a related discipline and must have had experience of recombinant DNA techniques.

Applicants should send a CV, including publications and the names of two referees, to **Prof. D. Onions, Director, Leukaemia Research Fund Centre, Department of Veterinary Pathology, University of Glasgow Veterinary School, Bearsden Road, Bearsden, Glasgow G61 1QH, from whom further details may be obtained.** (8176)A

THE ROYAL VETERINARY COLLEGE
University of London
Department of Veterinary Basic Sciences
POSTDOCTORAL RESEARCH ASSISTANT

An appointment is available to assist in a project to determine the molecular and cellular response to physical loadbearing in bone tissue. Experience in molecular and cellular biology is an advantage but not essential.

The project is supported by The Wolfson Foundation and the appointment will be for one year in the first instance with extension possible up to three years.

SALARY on the University Research Grade 1A scale, ranging from £11,515 to £17,370 per annum. Starting salary according to age and experience. Eligibility for Universities' Superannuation Scheme.

Further details may be obtained from Professor L E Lanyon (phone 01-387 2898).

Applications with a cv and the names of two referees to the **Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU.**

CLOSING DATE FOR APPLICATIONS: 23 February 1989 (8234)A

Medical Research Council
Radiobiology Unit
Cell and Molecular Biology Division

Molecular/Cellular Biologist

Applications are invited for a non-clinical scientific post which may be filled by either a SHORT TERM appointment of five years or a CAREER appointment according to the age and experience of the successful candidate. A career appointment will be tenable at this Unit in the first instance. The successful candidate will join a group studying molecular and cellular aspects of DNA repair and radiation mutagenesis, chromosome replication and aberration induction and the biophysics of radiation damage. Excellent research facilities are available and the Unit also includes groups studying mammalian genetics, radiation leukaemogenesis, cancer therapy and radiation chemistry. The postholder will be required to continue and expand the current programme on DNA repair and mutagenesis; in addition, a career appointee will develop his/her own programme of research and promote studies involving molecular biology.

Salary on scales equivalent to those for University non-clinical academic staff: Grade 2/1: £11,070–£19,310 or for Senior Grade up to £22,910 pa. Pension provided. The Unit is situated in a pleasant rural area equidistant to Newbury and Oxford. Hostel accommodation available.

Please send applications, including full c.v., publication list and the names and addresses of 2 referees, to the Personnel Officer, MRC Radiobiology Unit, Chilton, Didcot, Oxon, OX11 0RD. Please telephone Dr. John Thacker (0235 834393) for further information. Closing date: 24th February 1989.

The Council is an Equal Opportunity Employer (8226)A

UNIVERSITY OF BIRMINGHAM
DEPARTMENT OF CLINICAL CHEMISTRY
WOLFSON RESEARCH LABORATORIES
LECTURESHIP (NON-CLINICAL) IN CLINICAL CHEMISTRY

pplications are invited for this post of Lecturer (non-inical). The successful candidate will have a thorough aining and achievement in research and the ability to itiate and develop a research programme which comple-ents and extends the scientific interests of the Wolfson esearch Laboratories and the University School of Med-al Science. These include the development and clinical pplication of biochemical markers of malignant and ndocrine disease using molecular, cellular and novel nmonassay techniques. The Lecturer will contribute to esearch training and teaching of students, especially at ostgraduate level and formal qualifications in clinical hemistry are not essential.

alary will be within Lecturer A or B scales plus super-nnuation. It is anticipated that an experienced candidate f high calibre will be appointed on the Lecturer B scale urrently £15,105 – £19,310 pa).

urther particulars may be obtained from: **The Senior ssistant Registrar, University of Birmingham Medical chool, Vincent Drive, Birmingham B15 2TJ. Tel: 021 414 049 Ext 3377.**

o whom applications, including curriculum vitae and ames and addresses of three referees should be sent not ter than: February 24 1989. (8188)A

IVERPOOL SCHOOL OF TROPICAL MEDICINE
(University of Liverpool)
Department of Parasitology
OST DOCTORAL RESEARCH ASSISTANT

pplications are invited for the above MRC/EEC funded post which is ailable immediately for a period of 2 years with the possibility of tension for a 3rd year. The successful candidate will be involved imarily in applied immunological research on human hydatidosis d cysticercosis. The project has strong collaborative links in Kenya, ina and Mexico. Experience in both immunology and molecular ology would be advantageous. Starting salary within the range 865-£10460 pa. Applications with full c.v. and three references ould be sent by 10 February 1989 to **Dr P S Craig, Dept of Parasitology, verpool School of Tropical Medicine, Pembroke Place, Liverpool 5QA.** The Liverpool School of Tropical Medicine is an Equal Oppor-nity Employer. (8205)A

UNIVERSITY OF SUSSEX
POSTDOCTORAL POSITION IN MOLECULAR GENETICS

plications are invited from candidates interested in membrane otein structure and assembly for the above MRC-funded post.

e successful candidate will use a newly developed gene fusion stem to analyse the membrane organisation and mechanism of embrane insertion of selected eukaryotic membrane proteins. Prev-us experience in rDNA technology would be useful, but is not sential.

e project is funded for 3 years on the RA1A scale (£9,865 – £11,070 a.) and is available to start immediately.

.v. with the names and addresses of two referees, should be sent to **Jenny Broome-Smith, Microbial Genetics Group, School of ological Sciences, University of Sussex, Falmer, Brighton BN1 G, E. Sussex.**

EQUAL OPPORTUNITY EMPLOYER (8233)A

PLANT BREEDING INTERNATIONAL
NEW OPPORTUNITIES WITHIN OUR EXPANDING SCIENCE GROUP
ASSISTANT MANAGERS/RESEARCH ASSISTANT

Two assistant managers and one research assistant are required for two different teams, one working on the molecular biology of plant viruses, and the other on the molecular biology of potato nematode disease resistance. The assistant managers will have line management responsibilities.

Qualifications: Either a HND, BSc or equivalent, and laboratory experience in molecular biology and/or biochemistry, extensive in the case of assistant managers, together with a high degree of care and reliability in experimental work.

For further particulars telephone Cambridge 840411 ext 307, or write to the **Personnel Officer, PBI Cambridge Ltd, Maris Lane, Trumpington, Cambridge CB2 2LQ quoting Ref: SCI/42/43.**

An Equal Opportunities Employer (8231)A

RESEARCH FELLOW
$A31,003-$A38,045

DIVISION OF RADIOPHYSICS
MARSFIELD, NSW AUSTRALIA

THE DIVISION: The Division of Radiophysics, a Division within the Institute of Information and Communications Technologies, provides research, development and consulting for signal and image processing, VLSI design, gallium arsenide design, millimetre and microwave technology receivers, earth station and satellite antennas. It is the host institution of the Australia Telescope, and has a highly regarded international reputation in the area of radio astronomy.

THE GROUP: The Signal and Imaging Technology Group within the Division is currently involved in the areas of VLSI design, ultrasonics, radar systems, tomographic imaging, medical electronics, special purpose high-speed processors for image processing, and other aspects of signal processing. The potential of using new technology together with theoretical research in signal and image processing techniques forms much of the work within the group. Much of this work is done in cooperation with Australian industry, although some of the work is applied to the radio astronomy research being undertaken by the Division.

THE JOB: The appointee will undertake research associated with the application of modern interactive image processing technology to novel geophysical techniques being developed for the coal industry. This project is being carried out under contract to the Australian Coal Industry Research Laboratories and involves collaboration with Macquarie University. The appointee will be required to liaise closely with geophysicists from these groups in the evolution of techniques for both measurement and processing. To this end it will be necessary for the appointee to participate in underground surveys.

THE PERSON: Applicants should hold a PhD degree or equivalent qualification in electrical engineering or geophysics, with demonstrated ability in original research. Extensive experience with numerical computation is essential. Expertise in modern image reconstruction technology, familiarity with geophysical practice and some knowledge of geology would be of considerable benefit.

CONDITIONS: Appointment will be for a term of 2 years, with Australian Government superannuation benefits available.

ENQUIRIES: Prospective applications are invited to contact Mr Glynn Rogers or Dr John O'Sullivan (02) 868 0222 for further information.

APPLICATIONS: Applications should be submitted by 24th February and should quote reference number A7002. They should provide details of relevant personal particulars, including qualifications and experience. The nomination of at least two professional referees should also be included. Applications should be addressed to:

Advanced Drug Delivery Research

Head of Molecular Cell Biology

Horsham, West Sussex, U.K.

The Advanced Drug Delivery Research Unit of Ciba-Geigy Pharmaceuticals is working at the forefront in the design of methods for achieving the site-specific delivery of conventional and genetically defined drugs. A senior position has become available within the Unit for an experienced Cell Biologist. This person will act as the scientific leader of a multi-disciplinary project team comprised of up to 20 staff working on achieving the epithelial and endothelial transport of macromolecules.

This is an exciting career opportunity for a creative and effective senior scientist with a renowned track record in cell and molecular biology and possessing proven team leadership skills. The successful applicant will preferably have had at least 10 years' post-doctoral experience as well as industrial and international experience.

The remuneration package offered reflects the seniority of this position, and includes comprehensive relocation assistance where appropriate.

Candidates wishing to discuss this position in confidence may contact Professor Eric Tomlinson, Head of the Advanced Drug Delivery Research Unit at Horsham (ext. 3638).

Applicants should send a full CV quoting ref: V40 to the Personnel Department, Ciba-Geigy Pharmaceuticals, Wimblehurst Road, Horsham, West Sussex RH12 4AB. Telephone: (0403) 50101.

PROFESSIONAL VACANCIES

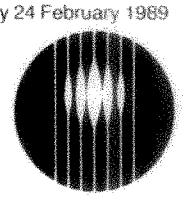
RESEARCH SCIENTIST/ SENIOR RESEARCH SCIENTIST (Several Positions)

$A30,100-$A43,801 p.a.

DIVISION OF APPLIED PHYSICS
SYDNEY, NSW, AUSTRALIA

Fields: Physics, electrical and mechanical engineering, and related fields.

General: The Division of Applied Physics undertakes research in Physics and Engineering and collaborates with industry to develop new or improved products and processes. It also maintains Australia's primary standards of measurement for a wide range of physical quantities and undertakes research related to the development of new or improved standards. Most of the Division's staff, numbering about 300 in all and including some 130 professional scientists, are located at a modern laboratory in the Sydney suburb of Lindfield. The research of the Division is carried out in five programs: Electrotechnology; Applied Electricity and Magnetism; Plasmas, Thin Films and Thermometry; Acoustics and Mechanics; and Optical Technology. Vacancies exist in these programs and we seek applications from experienced scientists who believe they have attributes that would enable them to make innovative contributions both to existing and future projects.



Duties: To undertake research within one of the programs listed above. Current projects include: superconductivity at low and high temperatures and related device applications; systems for the transport of bulk materials; fabrication and application of new magnetic materials; electricity supply technology; plasma applications, e.g. in materials processing; surface modification and thin film technology; applied ultrasonics; optical information processing; fabrication and coating of high-quality optical components; and several projects on measurement science, related to mechanical, electrical, acoustical, optical and temperature measurement technology, both in the standards context and for specific industrial applications. Further information may be obtained by phoning Dr John Collins on (02) 467 6324.

Qualifications: Ph.D or equivalent in a relevant field of science or engineering plus a proven record of achievement in independent research indicating self motivation and adaptability. Experience working in or with Industry would be an advantage.

Tenure: Indefinite with Australian Government Superannuation benefits available.

Applications: Applications should be submitted by 24 February 1989 and quote reference No. AS88/22. They should include relevant personal particulars, including qualifications and experience and the names of at least two professional referees, and be addressed to:

The Chief,
CSIRO Division of Applied Physics,

CSIRO IS AN EQUAL OPPORTUNITY EMPLOYER (W5774)A

GBF

Gesellschaft für Biotechnologische Forschung mbH —
The National Research Centre for Biotechnology, Braunschweig, Federal Republic of Germany

seeks two experienced

IMMUNOLOGISTS/CELL BIOLOGISTS

for the Division of Microbiology.

Two posts are available, one which is tenured for a senior scientist (No. 14/89), the other of which is available for two years (renewal possible) for a postdoctoral fellow (No. 15/89).

Requirements and Responsibilities
Candidates for both posts should possess a doctoral degree in medicine of science and have extensive experience (documented by excellent publications) in immunology and with modern immunological methods. The persons appointed will camp out fundamental research on intestinal immune and non-immune defences against microbial infections. They will interact closely with microbiologists and geneticists of the Molecular Medical Mircobiology group that are studying pathogenesis mechanisms of and developing vaccines against bacterial intestinal pathogens. The more senior appointee will additionally be responsible for setting up and supervising a monoclonal antibody facility for the Department of Microbiology, and thus extensive experience in tissue culture methods and hybridoma techniques is important. Appropriate resources will be made available for this facility.

Applications, which should be sent with the anounced number to the **Personnel Department, GBF, Mascheroder Weg 1, D-3300 Braunschweig, FRG**, should include a complete c.v., list of publications, reprints/preprints of the most important publications, a description of past and present research activities, and the names and addresses of three persons willing to provide critical references. (W5777)A

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
DEPARTMENT OF MEDICAL MICROBIOLOGY

Position with honorary College appointment for Post Doctoral molecular biologist to collaborate with virologists in research on drug resitant HIV. Experience preferred in application of PCR and DNA sequencing. Academic associates in discipline already present. Salary available for immediate appointment with three years MRC support.

Apply to Professor George Gee Jackson or Dr John Oxford, Department of Medical Microbiology, The London Hospital Medical College, Turner Street, London E1 2AD (Tel: 01-377 7141). (8185)A

Christie Hospital & Holt Radium Institute

PATERSON INSTITUTE FOR CANCER RESEARCH

Department of Carcinogenesis

RESEARCH SCIENTIST

Experienced post-doctoral scientist required to participate in one or more aspects of the group's work on molecular mechanisms of cancer causation and treatment, with particular emphasis on DNA damage and repair.

She/he would be expected to generate new research programmes within the framework of the group's interests. Experience in gene transfer techniques, especially the use of retroviral vectors or transgenics, or methods for the detection of DNA damage in human tissues could be relevant.

MRC conditions of employment and remuneration depending upon age and experience.

Please send CV and an outline of research interests to Dr P J O'Connor, Head, Carcinogenesis Department, Paterson Institute for Cancer Research, Christie Hospital & Holt Radium Institute, Manchester M20 9BX, U.K.

FUNDED BY THE CANCER RESEARCH CAMPAIGN (8221)A

THE AUSTRALIAN NATIONAL UNIVERSITY

Applications are invited for appointment to the following position:

FACULTY OF SCIENCE
FIXED-TERM LECTURER IN CHEMISTRY

Duties will include teaching to undergraduate and graduate students and conducting research in chemistry. The appointment is for 3 years in the first instance with the possibility of extension. The appointment is in inorganic chemistry, preferably with a biological interest, although other areas will be considered. It is expected that an appointment will be made mid-year. For further information contact the Head of the Department of Chemistry, Dr Ben Selinger (062) 492391 or Dr John Broomhead (062) 492934.

Closing date: *13 March 1989.* Ref. FS.23.12.1

SALARY: A$30,737–A$40,100 p.a. APPLICATIONS should be submitted in duplicate to the Registrar, The Australian National University, GPO Box 4, Canberra ACT 2601, Australia, quoting reference number and including curriculum vitae, list of publications and names of at least three referees. The University reserves the right not to make an appointment or to appoint by invitation at any time. Further information is available from the Registrar, or from Appointments (35929), Association of Commonwealth Universities, 36 Gordon Square, London WC1H 0PF.

BP VENTURE RESEARCH FELLOW

Department of Biological Sciences

UNIVERSITY OF CALIFORNIA, SANTA BARBARA

Professor Ian K. Ross and his associates are investigating novel nuclear/cytoplasmic interactions that regulate differentiation in higher filamentous fungi (Basidiomycetes) under the auspices of the BP Venture Research scheme. The following postdoctoral position is available, offering opportunities to engage in challenging, new, research of considerable significance.

* A molecular biologist with a background in the molecular biology and biochemistry of fungi. Expertise in cloning and transformation techniques required. Experience in protein purification and characterization and/or immunological techniques would be advantageous.

Salaries for the Venture Research Fellow will be (US) $23,000-24,000. The appointment will be for three years initially, but may be renewable.

To apply, send curriculum vitae and three letters of recommendation to Prof. Ian K. Ross, Department of Biological Sciences, University of California, Santa Barbara, 93106, USA.

The University of California is an equal opportunity/ affirmative action employer. Applications from women and members of minority groups are strongly encouraged.

(8174)A

UNITED MEDICAL AND DENTAL SCHOOLS of Guy's and St Thomas's Hospitals

POSTDOCTORAL RESEARCH ASSISTANT

required in the Division of Surgery, St Thomas's Campus, to work on a project investigating the experimental effects of chemical manipulation on carcinogenesis. Candidates should preferably have a higher degree in biology, and a biochemical background would be advantageous.

Salary scale: £9,865 — £12,760 plus £1,650 London Weighting Allowance per annum depending on qualifications, experience and age. Appointment is for one year in the first instance.

For further information, please telephone Mr K G Burnand or Mr D Rutt on 01-928 9292 extns 2117 and 2424 respectively. To apply, please write with full CV and names and addresses of two referees to: **The Personnel Officer, UMDS, St Thomas's Campus, Lambeth Palace Road, London SE1 7EH, quoting reference No. STH/SURG/282(A).**

Closing date: 10 February 1989. (8181)A

WOLFSON POST-DOCTORAL RESEARCH FELLOW

required to join group in the Academic Department of Medicine at St. Mary's Hospital Medical School (Head of Department: Professor H.C. Thomas) to work on the molecular biology of delta hepatitis virus. Previous experience in gene cloning and general molecular biology techniques will be an advantage. Post funded by the Wolfson Foundation for a period of three years with starting salary of £13,330 pa inclusive of London Allowance.

Further enquiries to Dr. J. Monjardino (01-725 6381/1606).

Applications in form of full C.V. with names and addresses of 2 referees should be sent to **Personnel Department at above address. Please quote ref. 591.** (8183)A

UBC

The University of British Columbia

FACULTY OF SCIENCE

DEAN

Outstanding candidates are sought for the position of Dean of the Faculty of Science. The new Dean will take office July 1, 1989 or as soon thereafter as possible. The Faculty comprises eleven departments that offer B.Sc., M.Sc. and Ph.D. programs. The B.Sc. can also be earned in selected departments in the Faculties of Arts and of Medicine. There are more than 300 full-time faculty members.

The successful candidate will be a scholar recognized internationally in a field of research that enhances the Faculty. He or she will provide dynamic leadership within the Faculty and play a constructive part in the University's general academic leadership. The Dean will have proven administrative ability and will be dedicated to excellence in teaching.

Applications and nominations should be directed to **Dr. Daniel R. Birch, Vice President (Academic) and Provost, The University of British Columbia, 6328 Memorial Road, Vancouver, B.C. V6T 2B3, no later than March 31, 1989,** and must include a curriculum vitae, a list of publications and the names of at least three referees.

In accordance with Canadian Immigration requirements priority will be given to Canadian citizens and permanent residents of Canada. The University of British Columbia offers equal opportunity for employment to qualified female and male applicants. (NW3173)A

RESEARCH SCIENTIST
MOLECULAR GENETICS AND CARCINOGENESIS
CROSS CANCER INSTITUTE

The Cross Cancer Institute, a comprehensive cancer centre serving the population of northern Alberta, is seeking two molecular/cellular biologists for a tenure track position at the assistant or associate research scientist level. The successful applicants will join a highly interactive multi-disciplinary research group recently established under the aegis of the Alberta Heritage Foundation for Medical Research (AHFMR); the program is devoted to studying the molecular biology of human cancer. Candidates should hold a Ph.D. and/or M.D. degree(s), have relevant postdoctoral experience, and have a demonstrated potential for developing a vigorous and productive research program. While the specific area of research is not as important as excellence, preference will be given to applicants committed to advancing the understanding of human neoplasia in general and cancer cytogenetics, oncogenes/tumor-suppressor genes, control of gene expression, and developmental regulation in particular. Excellent start-up facilities and research support are available, as are opportunities to interact closely with basic and clinical researchers. The position has no formal teaching responsibilities but cross-appointment in the adjoining University of Alberta Medical School can be anticipated. Rank and salary (currently ranging from $38,000 to $57,000 per annum) will be commensurate with qualifications. The successful candidate will be encouraged to obtain AHFMR Scholarship support.

Interested persons should send a curriculum vitae, three reprints, and a synopsis of previous and proposed research, and also arrange to have three references directly forwarded to: **Dr. Malcolm C. Paterson, Director, Molecular Genetics and Carcinogenesis Laboratory, Cross Cancer Institute, 11560 University Avenue, Edmonton, Alberta, Canada T6G 1Z2.** To assure full consideration, applications should be received by May 31. In accordance with Canadian Immigration regulations, priority will be granted to Canadian citizens and permanent residents; however, others are strongly urged to apply. (NW3230)A

UNSW

THE UNIVERSITY OF NEW SOUTH WALES
SYDNEY, AUSTRALIA

Equality of employment opportunity is University policy

SCHOOL OF PHYSICS

RESEARCH ASSOCIATE

(Ref. 027)

DEPARTMENT OF CONDENSED MATTER PHYSICS

A position at the Research Associate level is available for a PhD graduate to work on an Australian Research Council funded project on theoretical physics. The project involves the interactions between nuclear spins in metals and electron spins in semiconductors and the consequent ordered structures. Preference will be given to applicants who have had experience in both analytical and numerical theoretical condensed matter physics.

Excellent conditions offered by the University include a garden setting with easy access to public transport, on campus parking, fully equipped sports centre with olympic pool and gym, shops, banking and credit union facilities.

Salary will be in the range $A26,617 to $A30,360 and a contribution towards initial removal expenses may be required. In addition generous leave, flexible working hours and study leave are provided.

Appointment will be initially for 2 years, with the prospect of extension for a further year.

Further information from Dr D. Miller on (02) 697 4582. (W5773)A

Please submit written application, quoting reference number and the names and addresses of two referees to: The Recruitment Officer, General Staff Office, P.O. Box 1, Kensington, N.S.W. 2033, Australia by 31 March, 1989.

A Cray X-MP supercomputer was installed in Finland at the beginning of 1989. The Centre for Scientific Computing, located in the Finnish State Computer Centre is responsible for operating the computer and developing its environment. Principal users of the computer include universities, the Institute of Meteorolgy, the Finnish State Technical Research Centre, and the Finnish State Computer Centre.

In order to further develop supercomputing in Finland we are now seeking a

SCIENTIFIC DIRECTOR

The scientific director will work directly under the manager of the State Computer Centre. The job contract is for a period of 2-5 years. The duties of the scientific director are the following:

- The main task is to promote supercomputing culture in all ways, both in scientific and applied computing.
- He/she must establish and maintain national and international connections necessary for supercomputing.
- He/she will make proposals to improve the environment of the supercomputer.

Candidates are required to have the competence level of a professor. In particular, international experience, connections to research groups in universities and in industry, and the ability to cooperate are considered beneficial.

For additional information, please contact the chairman of the scientific board, Dr Risto Raitio, Tel. 358-0-134171, network address RAITIO@FINFUN.BITNET.

Send applications to the secretary of the scientific board: Hannu Karttunen, VTKK/TLP 2106, Box 40, SF-02101 Espoo, Finland. Deadline for applications is 6 March 1989. The application should include a Curriculum Vitae, salary requirement and all documents the candidate wants to refer to. (W5796)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
(University of London)

POST-DOCTORAL RESEARCH FELLOW

DEPARTMENT OF IMMUNOLOGY

Applications are invited for a post-doctoral position, supported by an MRC programme grant, to work in the molecular immunology group of Dr Robert Lechler and Professor J R Batchelor. The aim of the proposed research project is to investigate the human T cell repertoire using T cell receptor gene cloning and gene transfection techniques. Applicants with experience in recombinant DNA technology are particularly encouraged to apply. Previous experience in immunoligical research is not essential.

Salary scale will be £11,070–£12,150 plus £1,650 London Allowance a year.

Application forms and further particulars available from the **Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0NN (tel: 01-740 3204)** quoting reference AIB2.

Closing Date: 2nd February 1989. (8170)A

RESEARCH OPPORTUNITY IN JAPAN

The Frontier Research Program at the **RIKEN** Institute of Physical and Chemical Research (see Nature 325: 569, 1987) invites applications for postdoctoral positions in the following areas:

— Molecular biology of the immune system and protein chemistry (purification and analysis of proteins) including expression of cloned genes and characterization of gene products at the Laboratory for Molecular Regulation of Aging headed by *Dr. Gabriel Gachelin.*

— Molecular biology of tumor suppresser genes, protein chemistry including characterization of proteins from the brains of Alzheimer patients, and biochemistry, molecular cell biology including eukaryotic cell during proliferation and differentiation at the Laboratory for the Aging Process headed by *Dr. Koiti Titani.*

— Molecular biology of phytochrome, including immunocytochemistry, isolation and analysis of genomic clones *in vivo* footprint analysis and site-directed mutagenetics at the Laboratory for Plant Biological Regulation headed by *Professor Masaki Furuya.*

— Nonlinear optics of organic materials, characterization and device application and organic molecular beam epitaxy technique at the Laboratory for Nonlinear Optics and Advanced Materials headed by *Professor Anthony F. Garito.*

— Protein design and synthesis, and bioelectronics at the Laboratory for the Bioelectronic Materials headed by *Dr. Kevin M. Ulmer.*

Appointments will be initially for one year and may be renewable thereafter.

These Laboratories are located at RIKEN Institute's two establishments in Wako, Saitama and Tsukuba, Ibaraki, on the outskirts of Tokyo.

Candidates should send a detailed curriculum vitae, a list of publications and the names of two individuals who may be contacted for references and summary of research interests to:
Director, Division of the Frontier Research Program,
RIKEN, Wako, Saitama, Japan
Zip code 351–01

(W5785)A

University College, London
Postdoctoral Research Associate
Membrane Biogenesis

A position is available immediately to work with Drs Paul Quinn and David Allan on a project funded by the Wellcome Trust to study the kinetics of membrane biogenesis in relation to the secretory pathway and the control of cell growth. Experience in membrane biochemistry or virology would be an advantage. The post, for one year in the first instance, carries an initial salary of up to £11,680 p.a. (under review) + £1,650 London Allowance.

Applications including c.v. and the names and addresses of two referees should be sent to **Dr P. Quinn, Department of Experimental Pathology, University College and Middlesex School of Medicine, University St, London WC1E 6JJ. Telephone: 01-380 9603 for further information.**

RHONE MERIEUX
N°1 in veterinary medicine

RHÔNE MÉRIEUX

Turnover : 1,2 billion FF - staff : 2000 worldwide

VIROLOGIST

Leader in veterinary research, 10 % of our turnover is invested in research.

To develop this research, we are looking for a virologist with well-based experience in general and systematic virology plus competence in biochemistry and/or immunology.

A doctor or veterinarian, he must prove his knowledge of pathology.

The job based in Lyons (France) implies a lot of travel. Knowledge of English and French desirable.

Please send letter of application, C.V. and pretentions to : **RHONE MERIEUX**
Personnel Department, P. O. Box 2006
69227 Lyon Cedex 02.

(W5797)A

TWO POST-DOCTORAL POSITIONS

are available. (1) Protein chemist with experience in immunochemistry or protein modification chemistry to investigate monoclonal antibody-photosensitizer conjugates as potential agents of cancer photochemotherapy. Familiarity with cell biology and photobiology highly desirable. (2) Biochemist/cell biologist to investigate the biochemical mechanisms of photosensitized damage to mitochondria of carcinoma cells. Experience in mitochondrial function studies desirable. Send CV to

Dr. T. HASAN,
WELLMAN LABORATORIES OF PHOTOMEDICINE,
HARVARD MEDICAL SCHOOL,
MASS GEN. HOSPITAL,
BOSTON, MA 02114.

Phone: 617/726-6996 (NW3175)A

ROYAL POSTGRADUATE MEDICAL SCHOOL
BONE MARROW TRANSPLANT UNIT
MLSO

A qualified MLSO interested in haematology and transplantation is required for our bone marrow transplant unit. Duties include assisting with bone marrow harvests, in vitro marrow processing and laboratory monitoring of recipients after unrelated donor bone marrow transplants. Previous experience in Southern blotting would be useful, but not essential. Study for higher degrees and participation in laboratory based research projects is encouraged. There are excellent library facilities at the RPMS.

Salary: £7415 £10148-£1267 London Allowance a year.

Application forms available from the **Personnel Office, Royal Postgraduate Medical School, 150 Ducane Road, London W12 0NN** quoting ref: AF23.

Closing Date: 15th February 1989 (8224)A

GEOMAR

C 3-POSITION IN PALEOCEANOGRAPHY International Distribution

GEOMAR, a Research Center for Marine Geosciences, was founded in 1987 at the Christian-Albrechts-University, Kiel, Federal Republic of Germany. Within this new Institution, the Paleoceanography Department has a position available for a **C 3-Professor in Paleoceanography** (approx. senior Associate/junior Full Professor). Applicants are expected to have demonstrated research and teaching experience in the field of paleoceanography. Apart from doing independent research work they are expected to participate in teaching marine geosciences at the Christian-Albrechts-University.

Applications from women candidates are strongly encouraged.

Applications with supporting documents and a short summary of research perspectives should be sent before **March 30, 1989** to: **the Dean, "Mathematisch-Naturwissenschaftliche Fakultät, Christian-Albrechts-Universität zu Kiel, Olshausenstraße 40, 2300 Kiel 1" Federal Republic of Germany.** (W5778)A

ANGLO-AUSTRALIAN OBSERVATORY
Research Astronomer

The Anglo-Australian Observatory comprises the 3.9-metre Anglo Australian Telescope and the 1.2-metre UK Schmidt Telescope nea Coonabarabran, NSW, and a laboratory in the Sydney suburb o Epping, Australia. There is currently a scientific staff of 14 astrono mers (including Fellows) nominated by the United Kingdom an Australia, plus a number of visitors and associated PhD students Applications are sought for one position which will become availabl in mid 1989.

Candidates should have a strong background in physics or astro physics. The appointment will be for a fixed term of 1 to 5 years, with salary in the range Aust. $31,003-$53,099 per year, plus other allow ances, fares, etc. The successful applicant will provide assistance t visiting astronomers and contribute to the development, mainter ance and general running of the telescopes and their instrumentatior An interest in infrared instrumentation and its use would be particu larly valuable. Approximately half of the appointee's time will b spent in personal research, and there will be opportunities for co laboration with Australian and British astronomers.

Applications should include:

1. age, nationality, qualifications and experience, and date PhD.
2. research proposals for AAT time during the first year of th appointment.
   Sufficient information is required to show that proposals a competitive with applications to the time assignment panels
3. any instrument development project in which applican have a particular interest.
4. any projects involving use of the UKST, or data from th plate library.
5. starting date and length of appointment envisaged.
6. names and addresses of 3 referees, whose references th applicants should arrange to be sent directly to the Directo

CHAIR, DEPARTMENT OF PHARMACOLOGY

The University of North Dakota invites applications and nominations for a chairperson of the Pharmacology Department in its School of Medicine. Candidates should have a Ph.D. or an M.D.degree, and strong credentials in research, grantsmanship at a national level, teaching in pharmacology, as well as an aptitude for effective administration. Selection will depend on professional qualifications and the potential to provide the talent and judgement to foster an effective research and educational program in Pharmacology. Review of applications will begin on 15 February 1989 and continue until a candidate is appointed.

Applicants are to provide a letter of application, curriculum vitae, a statement of research and representative publications, and cause three letters of recommendation to be forward to: **Dr. James J. Kelleher, Chair, Pharmacology Search Committee, Office of Academic and Research Affairs, University of North Dakota, School of Medicine, 501 North Columbia Road, Grand Forks, ND 58201.**

UND is an Equal Opportunity/Affirmative Action Employer.

(NW3223)A

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
DEPARTMENT OF MICROBIOLOGY
BEECHAM LECTURER IN INFECTIOUS DISEASE
(Non-Medical)

Applications are invited for the above limited tenure position (5 years). Salary will be within the non-clinical Lecturer Grade A scale (£9,260 x 8 to £14,500) with membership of the Universities Superannuation Scheme. This is a developmental position in which the successful candidate will take part in research on molecular aspects of the pathogenicity of infectious diseases and the design of molecular probes. The position will also involve the establishment of collaborative research and teaching links within the University aimed at the formation of a Molecular Pathogenesis Group. Applicants should have a microbiology training with experience at the postgraduate and postdoctoral level in the application of molecular biological techniques to microbiological problems.

For further details contact Professor J P Arbuthnott, Department of Microbiology, University Hospital, Queen's Medical Centre, Nottingham NG7 2UH. (Telephone 0602-421421 extension 3523).

Other particulars and a form of application may be obtained from the **Deputy Registrar and Secretary, Medical School, Queen's Medical Centre, Nottingham NG7 2UH,** to whom the completed application should be returned by the 20 February 1989. (8216)A

Statistics and Computing Statistician

A Statistician responsible for the statistical aspects of the research of the Divisions of Virology, Bacteriology and Immunobiology is required. The appointment will be initially for five years with the possibility of tenure at the end of that period.

The main duties will be the design and statistical analysis of national and international collaborate studies for WHO, and other organizations to evaluate proposed biological reference materials. There is also scope for the successful candidate to develop new statistical techniques or to collaborate in the development of computing projects, particularly in the area of expert and knowledge based systems.

Minimum qualifications are an honours degree and extensive postgraduate experience or a PhD in applied statistics. Experience in the applications of information technology in any of the following areas would also be an advantage statistics, molecular modelling, DNA and protein sequencing, databases or imaging.

The Institute is situated in a pleasant area of Hertfordshire within reasonable distance of London.

Salary will be in the range of £10,910 to £20,960 per annum inclusive, depending on qualifications and previous experience.

To apply please send a full curriculum vitae with the names and addresses of three referees to:
The Personnel Office, National Institute for Biological Standards and Control, Blanche Lane, South Mimms, Potters Bar, Herts EN6 3QG.
Telephone: 0707 54753 Ext 457.

NIBSC

Please quote reference SS/184. Closing date for applications is: 17th February 1989. (8187)A

Johann Wolfgang Goethe-Universität
Frankfurt am Main

The Department of Chemistry, Institut of physical and theoretical chemistry of the Johann-Wolfgang-Goethe-Universität invites applications for a permanent position (full professorship/C4) in

Physical Chemistry

subject to the usual university employment conditions (HUG§39a).

Applicants are expected to be able to represent the field of physical chemistry both in teaching and research.

The applicant's research field should be a topic of modern physical chemistry. It would be desirable if this field could supplement the present lines of research of the Institute, however, this is not a necessary condition.

Applicants with the necessary documents should be sent to the **Präsident der Johann-Wolfgang Goethe-Universität, Senckenberganlage 31–33, D6000 Frankfurt M.–1,** up to March 31, 1989. (W5799)A

Experimental Pathologist

Position is available for a person with an M.D. degree and trained in Anatomic and/or Clinical Pathology, and techniques of Molecular Biology. Candidate must have a demonstrated record of productivity as evidenced by prime authorship publications in critically reviewed journals and as Principal Investigator on USPHS grants or contracts. The candidate will be expected to initiate and maintain an independent, extramurally-funded research program. At least 75% of time will be available for research; and teaching Pathology to medical students and residents will be assigned.

Please send CV and a letter describing current and planned research goals, and the names of three references to:

John W. Kreider, M.D.
Division of Experimental Pathology
Department of Pathology
The Milton S. Hershey Medical Center
P.O. Box 850 Hershey, PA 17033

An Affirmative Action/Equal Opportunity Employer Women and Minorities Encouraged to Apply (NW3177)A

MEDICAL RESEARCH COUNCIL
NATIONAL INSTITUTE FOR MEDICAL RESEARCH
Genes and Cellular Controls Group

LABORATORY OF DEVELOPMENTAL BIOCHEMISTRY

Applications are invited for a three-year post-doctoral appointment to conduct research in association with Dr T J Mohun on transcriptional regulation of gene expression during early embryogenesis in Xenopus. The successful candidate will also have opportunities to collaborate with other members of the Laboratory and the Institute. The salary will be in the range of £12,520–£15,950 inclusive of London Weighting.

Applications including a curriculum vitae, list of publications, and names of two professional referees, should be sent to **Mr C R Russell, Administrative Manager, NIMR, The Ridgeway, Mill Hill, London, NW7 1AA,** not later than 17th February 1989 quoting reference 0569/GDBM.

An Equal Opportunities Employer. (8219)A

MRC Medical Research Council

IMPERIAL COLLEGE OF SCIENCE, TECHNOLOGY & MEDICINE
University of London

Applicants are invited for a

LECTURESHIP IN THE BIOCHEMISTRY AND/OR MOLECULAR BIOLOGY OF PHOTOSYNTHESIS

to be held within the Department of Pure and Applied Biology. The appointee will be expected to develop an independent research programme in the area of photosynthesis and should have an interest in the application of biochemical and molecular biological techniques. She/he will be closely associated with the AFRC Photosynthesis Research Group headed by Professor J. Barber and the Photochemistry Group headed by Professor Sir George Porter PRS.

Salary (inclusive of London Weighting) £10,910-£16,150.

Formal application, including curriculum vitae and the names of two referees, should be made to

Professor R.M. Anderson FRS, Department of Pure & Applied Biology, Imperial College, Prince Consort Road, London SW7 2BB by 28th February 1989.

Informal enquiries to: Professor J. Barber, tel. 01 589-5111, ext. 7433 or Fax. 01 225-1234. (8225)A

UNIVERSITY OF EDINBURGH
DEPARTMENT OF CHEMISTRY
Research Fellow

Applications are invited for the post of postdoctoral research fellow (RA1A) in the S.E.R.C. supported High Field N.M.R. Service which will be available to chemists, biochemists and biologists in U.K. universities. The successful applicant will be required to assist in the operation of the Varian VXR-600 and Bruker WH-360 N.M.R. Spectrometers under the direction of Dr. I.H. Sadler. The applicant should have practical experience in high resolution n.m.r. spectroscopy of large naturally occurring molecules including proteins and polypeptides. The appointment will be for 3 years in the first instance.

Salary scale: £9,865–£15,720.

Applications, which should include a curriculum vitae and the names of two technical referees should be sent as soon as possible to: **Dr. I.H. Sadler, Department of Chemistry, University of Edinburgh, West Nains Road, Edinburgh, EH9 3JJ.** PLEASE QUOTE REFERENCE NO. 5629 (8208)A

THE AUSTRALIAN NATIONAL UNIVERSIT

MOUNT STROMLO AND SIDIN SPRING OBSERVATORIES

POSTDOCTORAL FELLC IN ASTROPHYSICS

Applications are invited appointment as Postdoct Fellow in Astrophysics from 1989.

The Observatories (Direc Professor A. W. Rodgers) o ates seven telescopes on Stromlo and Siding Spring, in ding the new 2.3-m telescope, a wide variety of instruments optical direct imaging and pol metry, and photometry and s troscopy in the optical and in red. The main lines of research on evolutionary problems in st the interstellar medium, glob clusters, galactic structure, Magellanic Clouds, exte galaxies, radio and x-ray sou and large scale structure. A astronomers have access to Anglo Australian Telescope the aperture synthesis Austra Telescope. A PDS microph meter, VAX 11/785 and sev other VAX and MicroVAX c puters are available for data rec tion and image processing. University also has a Fuj VP100 supercomputer.

The Observatories curre comprise 20 academic staff about 80 professional techn and other support staff. There about 25 PhD students.

Closing date: *31 March 1* Ref: MS.12.1.1.

SALARY: Postdoctoral Fe Grade 1 (fixed point); A$26,6 A$30,360 p.a. APPOINTME normally two years, possibilit extension to three ye APPLICATIONS should be s mitted in duplicate to the Re trar, The Australian Natic University, GPO Box 4, Canb ACT 2601, Australia, quo reference number and inclu curriculum vitae, list of publ tions and names of at least th referees. The University rese the right not to make an appc ment or to appoint by invitatio any time. Further informatio available from the Registrar, from Appointments (359 Association of Commonwe Universities, 36 Gordon Squ London WC1H 0PF.

CARDIFF

PURE AND APPLIED BIOLOGY
RESEARCH ASSOCIATE

(Fixed Term — 2 Years)

EEC funded project on the transfer, spread and survival of plasmid DNA in epilithic bacteria. Research involves travel to Belgium, Spain, Portugal and Germany. PhD in Microbiology or Genetics is essential.

Salary: £9865–£15720 per annum.

For further particulars and application form please write to **the University of Wales College of Cardiff, PO Box 431, Cardiff CF1 1TA, quoting Ref 88/171.**

Closing Date: 13 February 1989.

(8228)A

ASSOCIATE OR FULL PROFESSOR
MOLECULAR BIOLOGY

A tenured position is available in the Rosenstiel Basic Medical Sciences Research Center as a joint appointment with the Graduate Department of Biochemistry. We seek candidates who are investigating basic mechanisms in molecular biology, in fields ranging from replication to gene expression. Curriculum vitae should be sent to:

Dr. David DeRosier
Rosenstiel Basic Medical Sciences Research Center
Brandeis University
P.O. Box 9110
Waltham, MA 02254–9110

The deadline for applications is 1 March 1989. *Brandeis University is an Equal Opportunity/Affirmative Action Employer.*

(NW3205)A

Harvard Medical School and Children's Hospital Boston, MA

Assistant or Associate Professor. Major emphasis is on Cell and Molecular Biology of connective and skeletal tissue, cells and noncollagenous proteins. Candidate should be experienced in isolation and characterization of proteins and genes.

Write or send résumé to: **Dr. Melvin J. Glimcher, M.D., Children's Hospital, Enders Building 11th Floor, 320 Longwood Ave., Boston, MA 02115.**

(NW3207)A

DEPARTMENT OF BIOCHEMISTRY UNIVERSITY OF OXFORD

OXFORD LINK CENTRE
EUKARYOTIC MOLECULAR GENETICS
POSTGRADUATE RESEARCH ASSISTANT
Grade 1B BR/281

Applications are invited from suitably qualified persons for the above position in this active Centre under the direction of Drs. S. M. and A. J. Kingsman.

The research aims to study proteins that regulate viral gene expression in animal cells. Experience in virology, cell culture, or recombinant DNA techniques would be an advantage but applicants with backgrounds in other areas of Biochemistry and Cell Biology will be considered.

The position is available immediately and funding has been obtained for three years in the first instance.

Salary on the scale £8,675-£13,365 per annum.

Applications, including a curriculum vitae and the names and addresses of two referees, should be sent to: **The Administrator.**

An Equal Opportunity Employer. (8209)A

DEPT OF BIOCHEMISTRY, SOUTH PARKS ROAD,OXFORD,OX1 3QU

INSTITUTE OF CANCER RESEARCH
Sutton, Surrey
Technician

A Technician is required in the Joint Department of Physics of the Institute of Cancer Research and the Royal Marsden Hospital to assist with research aimed at improving the effectiveness of ultrasound as applied to the diagnosis and management of cancer. The post is primarily concerned with the management, processing and statistical analysis of data acquired from ultrasound images, using ORACLE relational database management software and the SAS statistical package on IBM PC and DEC VAX computers. It would thus be suitable for a new graduate in statistics, a physical science, or a related subject. An ability or an interest in learning to write computer programmes in FORTRAN is also desirable. Much of the work requires close co-operation with medical personnel. Suitable candidates must therefore be able to express themselves clearly and have good communicating skills.

The Physical Section has an active and broad-based research and teaching programme and provides a stimulating environment for someone wishing to work in the biomedical field. The post will be based at the Sutton, Surrey campus with occasional need to travel to our other branch at Fulham, London. Good sports and social facilities are on-site.

Salary in the range of £7811 to £10711.

Applicants are advised that smoking is prohibited in the majority of the Institute's premises.

Informal enquiries can be made to Dr. J.C. Bamber on 01-642-6011, ext. 3343.

To apply, please submit a Curriculum Vitae in duplicate with the names and addresses of two professional referees to the **Personnel Office, The Institute of Cancer Research, 17A Onslow Gardens, London SW7 3AL** quoting reference number 1.89.T.N.65.

INORGANIC CHEMISTRY LABORATORY
Appointment of Adminstrator

Applications are invited for the established post of Departmental Administrator on the Academic-related administrative Grade 4 scale, £17,630 to £20,920.

The Administrator is responsible to the Head of Department for all matters concerning the non-teaching staff, external grants and the departmental accounts, the purchase of equipment, the technical and office staff and the maintenance of the building.

Further particulars may be obtained from **Dr M.L.H. Green, Inorganic Chemistry Laboratory, South Parks Road, Oxford, OX1 3QR, to whom application, with a curriculum vitae and the names of two referees, should be sent by 17 February 1989.** (8229)A

The University is an Equal Opportunity Employer

ZOOLOGY
UNIVERSITY OF TORONTO

The Department of Zoology invites applications for a tenure-track position at the rank of Assistant Professor to begin 1 July, 1989, or thereafter. We are seeking an outstanding and innovative scientist who has recently received his/her Ph.D. (post-doctoral experience preferred). The successful candidate will be expected to establish a vigorous, independent research program, preferably of environmentally related vertebrate physiology and to teach at the undergraduate and graduate levels. Salary, currently between $31,500 and $53,600 for an assistant professor, will be commensurate with experience and qualifications. Applications to be submitted by 15 February, 1989, should include an up-to-date curriculum vitae, an outline of future research plans and names, addresses and telephone numbers of three referees.

If they wish, applicants may arrange with referees to send letters on their behalf. Please send documentation to **Dr. Michael Barrett, Physiologist Search Committee, Department of Zoology, University of Toronto, Toronto, Ontario, Canada M5S 1A1; (416) 978-3488.**

In accordance with the Employment Equity Policy of the University of Toronto, applications are invited from all qualified women and men. (NW3196)A

THE UNIVERSITY OF TEXAS Southwestern Medical Center AT DALLAS
Department of Biochemistry

POSTDOCTORAL FELLOW POSITIONS BIOCHEMISTRY AND GENETICS OF PROTEIN TRANSPORT

Positions are available to examine the molecular genetics of protein and ribonuclear protein transport across organelle membranes in yeast. Studies will focus on *in vitro* transport methods in conjunction with available genetic and immunological probes to define structure function relationships of the transport apparatus within the nuclear envelope and mitochondrial membranes. Send curriculum vitae or call 214-688-2120, **Dr. Michael G. Douglas, Department of Biochemistry, UT Southwestern Medical Center, 5323 Harry Hines Blvd., Dallas, Texas 75235-9038.** An equal opportunity employer. (NW3221)A

POSTDOCTORAL POSITION

Available immediately to study human B cell differentiation. Research in progress includes determining the usage of immunoglobulin variable region genes during ontogeny, especially of CD5 (Leu-1) positive B cells. Experience in molecular biology is desirable. Please submit a letter describing current and past research activities, c.v. and the names of two references to: **Carol Nottenburg, Ph.D., Division of Clinical Research, Fred Hutchinson Cancer Research Center, 1124 Columbia St., Seattle, WA 98104.** FHCRC is an AA/EEO, M/F/H employer. (NW3191)A

UNIVERSITY OF GLASGOW
Department of Physics and Astronomy

Applications are invited for two post-doctoral research posts in theoretical particle physics, both tenable for two years, from 1 October 1989.

Areas of interest to the group include:

1) electro-weak interactions, physics beyond the standard model and particle physics in cosmology;
2) numerical simulations of quantum field theories.

It is intended that one appointment would be made for collaboration in areas (1) and the other for collaboration in area (2).

The posts are funded through an SERC grant and appointment would be made at the usual UK salary (Range 1A for Research and Analogous staff) corresponding to age, up to age 27 on 1 October 1989. Applicants should send their curriculum vitae and request two referees to write, before the closing date of February 17th, to **Professor R.G. Moorhouse, Department of Physics and Astronomy, Glasgow University, Glasgow G12 8QQ.** (8210)A

THE UNIVERSITY OF LEEDS
DEPARTMENT OF BIOCHEMISTRY
POSTDOCTORAL RESEARCH FELLOW

Applications are invited for the above post, commencing 1st April, 1989 or as soon as possible thereafter for a fixed term of 36 months, to study the actions and metabolism of extracellular ATP inhuman articular cartilage.

The project is funded by a grant from the Wellcome Trust to Dr. A M Caswell and Professor R G G Russell (Department of Human Metabolism and Clinical Biochemistry, University of Sheffield Medical School).

Applicants should have a PhD or equivalent relevant experience preferably of tissue culture techniques.

Informal enquiries may be made to Dr A M Caswell (0532) 333114.

Salary on the RA IA scale (£9,865 – £11,070) according to qualifications and relevant experience.

Application forms and further particulars may be obtained from and completed applications forwarded to the **Registrar, the University, Leeds LS2 9JT (tel 333963 – direct line), quoting reference number 83/93.** Closing date for applications 16 February 1989. (8200)A

LA TROBE UNIVERSI
Melbourne, Australia

CHAIR OF GENETICS A
HUMAN VARIATION
School of Biological Scien

Applications are invited appointment to the Chair of (etics and Human Variation i School of Biological Scie which has become vacant fol ing the resignation of the fou tion professor, Professor I Parsons.

Research and teaching activ in the Department encompa broad spectrum of interests cluding human genetics, (d graphic, anthropological health, immunogenetics cancer genetics, molecular etics); ecological and conserva genetics (plants, insects, n mals, marine invertebra evolutionary genetics (ins marsupials, plants); and molec and cell biology or eukary especially mammals. A n strength of the Department diversity of approaches to study of the phenomena heredity.

The University invites app tions from distinguished scier in any field of genetical resea The successful applicant will sess an outstanding research b ground in his or her chosen f and will be expected to der strate strong academic leade and a dedicated commitmer teaching within the Departme

The University reserves right not to make an appointi or to make an appointmen invitation.

Salary: A$63,397.

Applications should quote erence number 150-0-217 an clude a curriculum vitae and names and addresses of t referees. The application, ma 'In Confidence', should be warded to the Manager, Sta and Secretariat, La Trobe versity, Bundoora, Victoria 3 Australia, by 31 March 1 Applicants resident in the should also send a copy Appointments (35948), Ass tion of Commonwealth Univ ties, 36 Gordon Square, Lor WC1H 0PF, from whom fur particulars are available.

ETH-Zürich, Switzerland

available to study the molecular basis of **chromosome- and chromatin structures in yeast** with respect to gene expression, replication, and DNA repair (Thoma & Zatchej, 1988, Cell 55, Dec. 23). The position is available for 3 years starting April 1989. The salary will be US$ 38000 to 44000 (Swiss National Science Foundation) depending on experience.
The candidate should have competence in yeast genetics and/or molecular biology and/or immunological techniques. Please call or send application to: **Dr. Fritz Thoma, Institut für Zellbiologie, ETH-Hönggerberg, CH-8093 Zürich, Switzerland. Tel: 0041-1-3773323 or 0041-1-3773352.** (W5793)A

THE UNIVERSITY OF LEEDS
DEPARTMENT OF MICROBIOLOGY
LECTURER

Applications are invited for the above post available from 1 December 1989.

Qualifications and special interests in molecular biology of herpesvirus required.

Salary on the Academic Scale for Lecturers Grade A (£9,260-£14,500) or Grade B (£15,105-£19,310) according to qualifications and relevant experience.

Informal enquiries may be made to Professor D H Watson (tel (0532) 335647).

Application forms and further particulars can be obtained from and completed applications forwarded to the **Registrar, the University, Leeds, LS2 9JT,** (tel (0532) 333963) quoting reference number 96/45. Closing date for applications 17 February 1989. (8215)A

ASSISTANT/ ASSOCIATE MEMBERS

The James N. Gamble Institute of Medical Research is seeking investigators in the Division of Enteric Viruses. Minimum requirements for successful candidates will be completion of postdoctoral studies and the ability and interest to establish or continue active research programs. Preference is for applicants specializing in viral immunology, molecular biology of enteric viruses, or animal modeling of human enteric viral diseases. No formal teaching will be required but a joint appointment at a local university is encouraged. Salaries and benefits are highly competitive and start-up funding will be available. Applications should be sent to: **R. L. Ward, Director, Division of Enteric Viruses, Gamble Institute of Medical Research, 2141 Auburn Avenue, Cincinnati, PH 45219.** *Equal Opportunity Employer.* (NW3210)A

THE HANNAH RESEAR INSTITUTE AND UNIVERSITY OF CARD

A post is available immediat the postgraduate level to j team studying the regulati adipose tissue development ferent body sites in sheep approach involves both stud vivo and in vitro, with exte use of cell culture techniques team comprises two groups t at Cardiff and the Ha Research Institute.

The post is funded for two by the AFRC University Research Group Scheme; th ary will be on the Universit (B) scale.

Further information car obtained from either Drs Ve or Flint (0292) 76013 or Dr ((0222) 874127. Applica should be submitted to The Sc ary, The Hannah Research tute, Ayr KA6 5HL, Scotlar 10 February 1989 quoting ence HRI/164. (8171

INSTITUTE O NEUROLOG
QUEEN SQUAR

1. POSTDOCTORAL RESEARCH ASSISTANT
(grade 1A, salary scale £9,865-£11,070 plus £1,65 London Allowance.

2. RESEARCH TECHNICI
(University grade 3, salary sc £6,636-£7,008 plus £1,750 London Allowance.

Candidates for the above posts required for studies of the m chondrial genome in patients defects of the respiratory c (mitochondrial myopathies). project is for three years an funded by the Muscular Dystro Group of Great Britain and North Ireland. Work will concentrate patients shown to have deletion muscle mitochondrial DNA, in ticular analysing breakpoint reg and the distribution of dele mtDNAs in muscle using in hybridization. Experience of r vant techniques is desirable for (1); training can be provided for (2).

Further particulars can be obtai from Dr A E Harding, Departm of Clinical Neurology, Institut neurology, Queen Square, Lon WC1N (tel 01 837 3611 ext 42 to whom applications (curricu vitae and the names of two refer should be sent within two week the date of this advertisem (8190)

Opportunities in Drug Discovery Research in Japan

Pfizer Central Research at Nagoya, Japan, is offering excellent career opportunities in our expanding drug discovery research programs. The laboratories located 35 km south of Nagoya city are an integral part of Pfizer Central Research worldwide and Pfizer Taito Co. Ltd., a Pfizer Inc. subsidiary. We are seeking Japanese scientists at the Ph.D. level with degrees in Biochemistry, Immunology, Pharmacology, Microbiology, and Organic Chemistry, and 1-3 years of post-doctoral or industrial experience. In addition to strong technical expertise, all positions require extensive English communication skills and computer literacy. Specific requirements are as follows:

Immunologist/Biochemist

The successful candidate will have work expertise in cytokines, cell surface receptors, and lymphocyte activation. Initially, he or she will be responsible for developing *in vitro* assays aimed at accomplishing several goals, including evaluation of the role of different mediators in the immune response. Knowledge of tissue culture techniques is essential.

Pharmacologist

A broad knowledge of, and experience with, various animal models of inflammation is essential. The successful candidate will be responsible for developing animal models of arthritis and autoimmunity. Some background in general pharmacology and cellular immunology is desirable.

Microbiologist

A strong background in biochemistry and molecular biology of micro organisms is essential. Knowledge of taxonomy is desirable.

Natural Products Chemist

The successful candidate will become a member of our discovery fermentation group. Experience in modern isolation techniques and spectral methods is essential.

Organic Chemist

Applicants should have extensive expertise in organic synthesis. Responsibilities include design and synthesis of biologically active compounds. Keen interest in the biological aspects of drug discovery is essential.

Pfizer Taito offers a competitive salary and excellent benefits, including a relocation package. Qualified applicants should submit their resumes and a brief description of their research accomplishments to **Mr. Kenji Takamatsu, Director of Personnel, Pfizer Taito Co. Ltd, P.O. Box 226, 1-1 Nishi-Shinjuku 2-Chome, Shinjuku, Tokyo 163, Japan.**

ファイザー名古屋中央研究所

GROUP LEADER POSITION IN MOLECULAR NEUROBIOLOGY

Friedrich Miescher-Institut Basel, Switzerland

The Friedrich Miescher-Institut, a foundation devoted to basic research in cell biology, invites applications for an independent group leader position in neurobiology. Candidates are sought who have an interest in using molecular biology techniques to study the differentiation and the regeneration of the neuronal cell in vitro and in vivo. The candidate should have at least three years postdoctoral experience in molecular aspects of cellular neurobiology. The appointee's group will join two other groups working in the field of neuronal development, led by Dr. Andrew Matus (cytoskeleton) and Dr. Denis Monard (growth factors).

The Institute has strong research programs in cellular and molecular biology and offers an outstanding scientific environment with excellent research facilities. Employment conditions for the offered position are highly competitive. The envisaged starting date is mid-1989 or later. Applications, including an outline of the candidate's proposed research project, should be submitted by February 28, 1989 to **Dr. Denis Monard, Friedrich Miescher-Institut, P.O. Box 2543, CH-4002 BASEL, Switzerland.**

(W5748)A

Biochemist/ Pharmacokineticist

Beecham Pharmaceuticals Research Division has a long established reputation for research and development of veterinary and animal health products and we are now seeking an experienced Honours graduate or post graduate scientist for our Veterinary Pharmacology Unit. The unit is concerned with evaluation of drugs for use in treatment of disease in domestic animals.

The post involves the setting up of a small group to carry out radio-labelled residue and balance studies on compounds in animals. Experience should include the design and execution of residue studies, and applicants should also be familiar with physico-chemical analytical methods for assay of drugs and metabolites.

Conditions of employment are attractive and include flexible working hours, a non-contributory pension and life assurance scheme. The laboratories are sited in rural Surrey and assistance may be given with relocation where appropriate.

To apply, write with full c.v. stating current salary, or telephone for an application form to the Site Personnel Manager, Beecham Pharmaceuticals Research Division, Walton Oaks, Dorking Road, Tadworth, Surrey KT20 7NT. Telephone 0737 364706.

Closing date for applications: 10 February 1989.

CELLULAR AND MOLECULAR PHYSIOLOGY

THE UNIVERSITY OF IOWA COLLEGE OF MEDICINE

Applications are invited to fill several positions this year at the ASSISTANT, ASSOCIATE or FULL PROFESSOR levels. We seek individuals with a strong record of research accomplishment using molecular biology, cell biology, protein chemistry or electrophysiology approaches to study mechanisms of intracellular and intercellular signalling, regulation of eukaryotic gene expression or structure and function of membrane proteins. Modern laboratory space and substantial startup funds are available. Excellent opportunities exist for participation in established interdisciplinary programs, including Cancer, Cardiovascular, Diabetes and Endocrinology Centers. Rank and salary will be based on academic and research record. Minimum requirements include Ph.D. or M.D. degree and two years of relevant postdoctoral training. Candidates should send a curriculum vitae, description of research activities, representative reprints, and request three letters of recommendation to be sent, preferably by March 15, 1989, to:

Dr. Richard Maurer
Chairman, Cell and Molecular Physiology Search Committee
Department of Physiology and Biophysics

RESEARCH INSTITUTE OF SCRIPPS CLINIC
DEPARTMENT OF IMMUNOLOGY
POSTDOCTORAL RESEARCH FELLOW

A postdoctoral position is available immediately for an immunologist/biochemist/molecular biologist to participate in studies of endocytosis of human histocompatibility antigens. Projects include biochemical and mutagenic analyses of structural requirements for endocytosis of histocompatibility antigens, analysis of intracytoplasmic processing/degradation pathways, and effects of endocytosis on the generation of immune responses. Experience with recombinant DNA techniques and protein analysis is desired. Salary is negotiable, depending upon experience. Send curriculum vitae and three letters of reference to: **Dr. Per A. Peterson or Dr. Shaokee Wu, Department of Immunology, Research Institute of Scripps Clinic, 10666 North Torrey Pines Road, La Jolla, California 92037.**

(NW3222)A

RESEARCH OFFICER

The Jersey Wildlife Preservation Trust is re-organising its research activities and needs a Research Officer to lead this work. Applications are invited from scientists with the following qualifications.

A PhD in a biological science and proven research experience; the ability to co-ordinate research projects through effective leadership; have the ability to write precise proposals, project outlines, grant applications and reports; use statistical techniques and computer systems; and to be able to work as a part of an enthusiastic professional team including animal curators and section heads involved in Jersey and overseas.

Applications must include curriculum vitae, description of research and career goals, publications (abstracts), statement of conservation philosophy, and names and addresses of three referees. Salary will be commensurate with education and experience and is linked to University research scales. Only non-family accommodation available.

Enquiries to: **The Zoological Director, Jersey Wildlife Preservation Trust, Les Augres Manor, Jersey, Channel Islands.** Closing date: 10th February, 1989.

RESEARCH SCIENTISTS MAMMALIAN CELL GENE EXPRESSION

Amgen, an industry leader in applied biotechnology, has an immediate need for 2 Research Scientists to contribute to our research programs in mammalian cell gene expression.

RESEARCH SCIENTIST CELLULAR PHYSIOLOGY

Dept. #347

This position requires a Ph.D. in mammalian cellular physiology and/or somatic cell genetics as well as a minimum of 2 years' postdoctoral experience in growth regulation and differentiation of animal cells. Familiarity with culturing various primary and established cell lines as well as experience in cloning and sorting cells and selecting metabolic and drug resistant mutants are essential. Some understanding and experience in cell culture scale-up are desirable.

RESEARCH SCIENTIST GENE REGULATION

Dept. #348

Qualified candidates for this position will have a Ph.D. and a minimum of 2 years postdoctoral experience in eukaryotic post-transcriptional gene regulation, including protein processing and secretion. Familiarity with glycosylation pathways and signal transport at the molecular level is essential.

Amgen offers an exciting and challenging research environment as well as an excellent compensation and benefits package including equity offerings. Qualified applicants should send a c.v. including references, in confidence, to:

UNIVERSITY OF LIVERPOOL

CANCER RESEARCH CAMPAIGN
Department of Radiation Oncology

Applications are invited for the non-medical post of J.K. Douglas Lecturer (Special Appointment) in Molecular Biology.

The successful applicant will be expected to interact with a group of 4 scientists investigating the potential of anti-sense oligonucleotides to inhibit oncogene expression, which has just commenced a 5 year Cancer Research Campaign programme grant. In addition the applicant would be able to develop his/her own interests in the molecular biology of cancer cells.

Initial salary on the Lecturer A or B scale (£9,260–£19,310 per annum). Grade III technical support and some recurrent expenditure will be available during the first two years of the appointment to enable the appointee to become rapidly productive.

The Department of Radiation Oncology is situated at Clatterbridge Hospital between Chester and Liverpool in a busy oncology department. Being close to both North Wales and the Lake District it offers excellent recreational opportunities.

Informal enquiries may be made to Professor Hilmar Warenius or Dr. David Tidd (051-334 7605).

Applications, together with the names of three referees, should be received not later than 20th February, 1989, by the **Director of Staffing Services (AS), The University, P.O. Box 147, Liverpool L69 3BX** from whom further particulars may be obtained. Quote Ref. RV/231/N.

An Equal Opportunity Employer. (8103)A

Cancer Research Campaign

POST DOCTORAL SCIENTIST

Beatson Institute for Cancer Research
Glasgow

A vacancy has arisen for a NUCLEIC ACID OR PROTEIN MOLECULAR BIOLOGIST to join an ongoing research programme funded by the Cancer Research Campaign investigating how sets of genes come to be co-expressed during erythroid cell differentiation. The position is for three years in the first instance with a salary in the range £11070-£14500. The Beatson Institute is a modern, well equipped laboratory comprising eight groups working in the fields of gene expression and tumour biology.

Applicants with relevant experience should send a complete CV to **Dr P.R. Harrison, The Beatson Institute for Cancer Research, Garscube Estate, Switchback Road, Glasgow G61 1BD (Tel: 041 942 9361).** (8204)A

UNIVERSITY OF TORONTO
BOTANY

The Department of Botany, University of Toronto (Scarborough Campus) invites applications for a tenure-stream position (Assistant Professor level) in cell biology or molecular genetics. Preference will be given to individuals familiar with recombinant DNA technology. The successful candidate will be expected to participate in undergraduate and graduate teaching and to develop a strong research program. Applicants should, by March 31, 1989, submit a curriculum vitae, including a statement of research interests, and have at least three letters of reference sent to **J.C. Ritchie, Acting Chair, Life Sciences Division, Scarborough Campus, University of Toronto, 1265 Military Trail, Scarborough, Ontario, Canada, M1C 1A4.** The University encourages both men and women to apply. In accordance with Canadian Immigration requirements priority will be given to Canadian citizens and permanent residents (landed immigrants) of Canada.

(NW3225)A

PEPTIDE CHEMIST/ MOLECULAR BIOLOGIST

— the professionals' choice

SENIOR BIOCHEMIST IN DRUG METABOLISM

Ware, Herts from £15,000

Glaxo Group Research is Britain's leading pharmaceutical research organisation with an enviable reputation for discovering and developing safe and effective medicines.

The Drug Metabolism unit of the Biochemical Pharmacology department is responsible for determining the metabolic fate of candidate drugs as part of their safety evaluation, and in aiding the design of better drugs.

Reporting to the Research Leader, you will plan, carry out and report studies on the metabolism, absorption, and excretion of novel compounds. You will use a range of biochemical and analytical techniques in these investigations and make full use of our extensive data acquisition and processing techniques. Comprehensive training will be given where appropriate.

You should have a degree or PhD in chemistry, biochemistry or a related discipline, and several years' experience in drug metabolism gained in the pharmaceutical industry or a similar environment. You should also have supervisory experience.

Experience in the use of various chromatographic and radiochemical techniques is expected and the possession of a Home Office Licence and experience of working to GLP standards would be an advantage.

Your starting salary will reflect your experience, and additional benefits will include a non-contributory pension scheme, profit-related bonuses and active sports and social club. Generous relocation assistance will be given where appropriate.

If you wish to take this opportunity of joining the market leaders, please write or telephone for an application form to Mr M J Linnane, Personnel Officer, Glaxo Group Research Limited, Park Road, Ware, Herts SG12 0DP. Tel: Ware (0920) 3993 ext 2293.

Glaxo Group Research

(8250)A

POSTDOCTORAL POSITIONS

Postdoctoral positions are available in cell, molecular and structural biology of membrane (D.W. Hamilton) and cytoskeletal systems (R.W. Linck). Membrane projects include: biogenesis during spermatogenesis, glycosylation, formation of the acrosomal, head and flagellar membranes, subsequent membrane maturation within the epididymis, and the function of membrane proteins. Cytoskeleton projects include: molecular structure and assembly of microtubules, gene structure and expression of microtubule proteins in development, and in vivo function of microtubules in cilia/flagella, centrioles/centrosomes and mitosis/meiosis. Experience is required in preferably more than one of the following: cytology, protein chemistry, immunochemistry, EM, diffraction methods, and/or recombinant DNA methods. Send curriculum vitae and three letters of reference to: **Dr. D.W. Hamilton or Dr. R.W. Linck, Department of Cell Biology and Neuroanatomy, University of Minnesota, 4-135 Jackson Hall, 321 Church Street, S.E., Minneapolis, MN 55455.** (NW3218)A

Director, Genetic Diagnostic Laboratory:

A position available immediately for a Ph.D. with experience in molecular biology/biochemical genetics to direct a genetic diagnostic laboratory. There is ample opportunity for independent research and faculty appointment at Duke University Medical Center (rank dependent on experience). The candidate will join an established and growing, comprehensive academic genetic and metabolic program with expertise in clinical genetics, molecular and biochemical genetics associated with a major mass spectrometry facility. Duke University is an Equal Opportunity/Affirmative Action Employer. Send curriculum vitae and three references to:

Y.T. Chen, M.D., Ph.D.
Associate Professor of Pediatrics
Division of Genetics and Metabolism
Department of Pediatrics
P.O. Box 3028
Duke University Medical Center
Durham, North Carolina 27710 (NW3161)A

RESEARCH MANAGER

CAMBRIDGE **Competitive salary + Car**

Agricultural Genetics Company Limited (AGC), a leading biotechnology specialist, was formed in 1983 to develop and market products and licensing opportunities in plant biotechnology. Products derived from AGC supported research have resulted in direct market launches and commercial partnerships worldwide. The Company currently funds over 100 research scientists in more than 50 specific teams in AFRC Institutes and British Universities and is structured around three strategic business units.

- Improved plants
- Microbial inoculants and Biological control agents
- Technology Transfer and Contract R & D

A vacancy has arisen in the corporate R & D research management team based at the Company's central office on the Cambridge Science Park.

The position of RESEARCH MANAGER will involve the identification, placement and management of research projects with commercial potential in research institutes and universities.

Applications are invited from candidates who are qualified to PhD level in one of the biological sciences with several years relevant research experience.

The company offers excellent conditions of employment including competitive salary, company car, company pension and health insurance schemes.

Please send your full CV and details of two referees to:

Dr Paul Boseley, Director of Research and Development, Agricultural Genetics Company Limited, 154 Science Park, Milton Road, Cambridge CB4 4GG

Closing Date for applications February 9th 1989

(8252)

POSTDOCTORAL FELLOW

A postdoctoral position is open for study of the biochemistry and cellular functions of membrane structural proteins in mammalian cells. Current projects include study of the proteins interacting with the spectrin-based membrane skeleton of brain and epithelial cells, and the role of spectrin and ankyrin in localization of membrane proteins at specialized cell domains such as nodes of Ranvier and basolateral domains of epithelial cells. Qualifications: Ph.D. with background and publications in either molecular biology, biochemistry, or cell biology. Please address applications to: **Vann Bennett, Howard Hughes Medical Institute, Department of Biochemistry, Duke University Medical Center, Box 3892, Durham, NC 27710.**

UNIVERSITY OF OXFORD

OXFORD CENTRE FOR MOLECULAR SCIENCES
Director: Professor J E Baldwin FRS

A new interdisciplinary research centre involving 10 departments at the University of Oxford has been established in the field of molecular and protein sciences with funding from SERC, MRC and industry. Research projects are concentrated in 6 areas: Blood clotting and fibrinolysis, Immunology; Signal transduction; Viruses; Enzymes of secondary metabolism; Protein folding and specificity. These projects will have access to the core research facilities of the Centre (crystallography, NMR spectroscopy, computation and graphics, glycobiology, organic chemistry) all of which are equipped to a very high level.

GRADUATE STUDENTSHIPS

A number of graduate studentships are available and we invite prospective graduate students to write for further information, giving some indication of their research interests.

POSTDOCTORAL FELLOWSHIPS

We invite those at a postdoctoral stage to write for further information, giving some indication of their research interests. In particular we have, at present, postdoctoral vacancies in the following areas:

FREE ENERGY METHODS
Computational chemist with a background in statistical mechanics or quantum chemistry to apply the free energy perturbation technique to protein-protein interactions and enzyme-inhibitor complexes.
Dr W G Richards, Dr G Lowe

ENZYME-BOUND INTERMEDIATES
Methods for investigating enzyme-bound intermediates by means of solid state NMR will be applied in mechanistic studies of β-lactamases. Experience of protein chemistry and/or NMR spectroscopy would be an advantage.
Dr S G Waley, Dr C M Dobson, Prof J E Baldwin, Dr A E Derome

STRUCTURE OF RECEPTOR FRAGMENTS
To investigate receptors associated with trans-membrane signalling. High resolution NMR, computation and molecular modelling will be used to determine structures of receptor fragments produced by peptide synthesis. Experience of structure determination by NMR and/or modelling would be an advantage.
Professor R J P Williams, Dr I D Campbell

NMR METHODS MULTIDOMAIN PROTEINS
NMR spectroscopist required to develop methods for the study of the structures, dynamics and folding properties of multidomain proteins, particularly those associated with blood clotting and fibrinolysis.
Dr C M Dobson, Dr C C F Blake, Dr P J Hore, Dr R A G Smith (Beechams)

COAGULATION FACTORS AND DOMAINS
Protein chemist with experience in protein purification and chemical modification of proteins required for work on structure & function of the various domains in coagulation factors and the proteins involved in fibrinolysis.
Dr C C F Blake, Dr I D Campbell, Prof R J P Williams, Prof G G Brownlee, Dr M P Esnouf

BLOOD COMPLEMENT SYSTEM
Protein chemist with strong molecular background required to work on synthesis of small structural domains found in blood complement system proteins, using yeast expression systems. Expressed domains will be used for analysis of tertiary sturcture by NMR & for functional studies.
Dr K B M Reid, Dr I D Campbell, Dr R B Sim

VIRAL AND SUBVIRAL STRUCTURES
Protein chemist and/or X-ray crystallographer required to work on crystallisation and structural analysis of various viruses and viral proteins using X-ray Laue diffraction.
Prof D H L Bishop, Dr J Hadju

INFLUENZA VIRUS NUCLEOPROTEIN
Protein chemist and/or crystallographer required for purification and X-ray structural analysis of influenza virus nucleoprotein (A and B subtype) to be purified from recombinant DNA sources.
Prof G G Brownlee, Dr D I Stuart

ANTIBIOTIC BIOSYNTHETIC ENZYMES
β-lactam biosynthetic enzymes cloned and expressed in *E. coli* will be prepared with isotopically labelled constitutent amino acids for structural and mechanistic NMR studies. This research will involve molecular biology and protein chemistry; experience in either area would be advantageous.
Prof J E Baldwin, Dr C M Dobson, Dr A D Derome, Dr A J Pratt

The Centre is funded for 6 years in the first instance, with all postdoctoral positions being tenable for 2 years initially, with the possibility of extension, on the scale RSAA1A £9865–£12760 (according to age and experience)

OMSC BORE STAFF POST NMR Spectroscopy

Research assistant required to join a small team who maintain and develop NMR spectrometers as well as work with a larger team who work on the structure and function of a variety of proteins. Excellent facilities include a 600 MHz, a 360 MHz and 2 500 MHz spectrometers, a micro vax and a cluster of SUN 4 computers. Some experience of sophisticated modern hardware is required, preferably with NMR.

The post is SERC funded for 5 years in the first instance on the scale RS1A £9865–£12760 according to age and experience.

TECHNICAL POSTS Peptide synthesis

OMSC has recently established a peptide synthesis facility which contains state of the art synthesis and purification equipment. A technician is required to operate and maintain an Applied Biosystems synthesiser, assisting members of the Centre to carry out peptide synthesis and to supply purified peptides to Centre members. Candidates with an interest in peptides and who have experience in some area of peptide or protein chemistry are preferred. HNC or equivalent is desirable but experience is of equal importance.

Microbiology

A technician is required to assist in the Microbiology facility. Duties will include preparation and maintenance of bulk enzyme stocks, enzyme purification, fermentation of genetically engineered bacteria, organisation and maintenance of laboratory equipment. Also making, dispensing and sterlising bacterial growth media. Experience of microbiological sterile technique is preferable and/or enzymology/biochemistry experience.

Both posts are SERC funded for 5 years in the first instance and on the scale T5 (£8,088–£9,549)

Applications for all posts should be made in writing, enclosing a full CV and the names of 2 referees and sent to **Sarah Hargreaves, Oxford Centre for Molecular Sciences, c/o Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY (0865 275654)**. Closing date for applications: 24 February 1989. (8236)A

PLANT MOLECULAR BIOLOGY/BIOCHEMISTRY ASSISTANT, ASSOCIATE, FULL PROFESSOR

The Department of Biology at The University of Michigan seeks applications for 2 positions. Both positions are on the tenure track, and one position is authorized at the level of Associate or Full Professor. We seek applications from individuals who utilize the techniques of plant molecular biology/biochemistry in attacking significant problems related to growth, development or metabolism in plants or algae. The department is now in a period of facilities renewal, and new faculty will be housed in modern laboratories. In addition, the Matthaei Botanical Gardens, a unit of Biology, provides excellent facilities for the growth of experimental material. Biology, in cooperation with the Department of Chemistry, has facilities for oligonucleotide synthesis and molecular graphics; peptide sequencing facilities are close at hand in the Medical School. The successful candidates will be expected to conduct active research programs and participate in the graduate and undergraduate teaching programs of the department. Applicants for a position at the Assistant Professor level should send a current c.v. and brief statement of future research plans. Applicants should also request letters of recommendation from at least 3 referees. Applicants for a tenured position should submit a c.v., statement of future research plans, and the names of 4 references. Candidates for the senior position will be contacted before references are sought, and all communications will be handled in strictest confidence. Application materials for both positions should be addressed to:

Chair, Plant Molecular Biology Search Committee
Department of Biology
The University of Michigan
Ann Arbor, MI 48109-1048

Evaluation of applications will begin on March 15, 1989 and continue until these positions are filled.

The University of Michigan is an Affirmative Action/Equal Opportunity Employer. (NW3237)A

Scientists

Paravax, Inc., an innovative new company focusing on the development o vaccines against parasites, has challenging opportunities for research scientist at all levels. Applicants should have training in one of the following areas:

- cDNA cloning methodology
- heterologous gene expression systems including living recombinant vectors
- mammalian or invertebrate cell culture.

A background in the immunology or molecular biology of parasitic disease or i veterinary vaccine development is also desirable. For consideration, pleas send résumé and names of references to:

Scientific Director, Paravax, Inc.,
3181 Porter Drive, Palo Alto, CA 94304 (NW3245)A

Paravax, Inc.

MOLECULAR BIOLOGY

Applications for a tenure-track position at the advanced assistant professor level are invited from scientists with experience in molecular biology. We seek applicants with sufficient experience to merit immediate consideration for promotion to associate professor with tenure. The appointee will be required to maintain an active research program and to teach a course and laboratory in molecular biology. Start-up funds and laboratory space are available for establishing a vigorous research program.

Oakland University is a state-supported institution situated on a 1,400-acre campus 25 miles north of Detroit. The Department of Biological Sciences is a well-equipped, research-oriented department in the College of Arts and Sciences.

Applicants should submit curriculum vitae, a description of their research plans, key reprints, and names of three references before 15 February 1989:

Dr. V.K. Moudgil, Chair, Search Committee
Department of Biological Sciences
Oakland University
Rochester, MI 48309-4401

Affirmative Action/Equal Opportunity Employer.

RESEARCH SCIENTIST PHARMACOLOGY

Amgen is a dynamic, growing organization producing human therapeutic products through recombinant DNA technology. Our leadership in the development of Erythropoietin and Granulocyte Colony Stimulating Factor has placed us at the leading edge of the biotechnology industry. Our continued growth has created an immediate opportunity for a Research Scientist in our Pharmacology Group.

Applicants must possess a Ph.D. in Pharmacology or a related discipline with a strong background in whole animal research and experience in one or more of the following areas: inflammation, wound repair, immunopharmacology, hematology and oncology. Proficiency in statistical analysis of data is essential, and postdoctoral training is highly desirable.

Amgen offers a competitive compensation and benefits package, including equity participation, as well as a challenging and stimulating research environment. Our location one hour northwest of Los Angeles offers the best in Southern California living. Qualified applicants should direct a resume and a list of 3 references, in confidence, to:

Recruitment, Dept. #372
AMGEN
1900 Oak Terrace Lane
Thousand Oaks
CA 91320 (NW3244)A

CLINICAL PROJECT MANAGERS

The Institute of Clinical Pharmacology (Irl.) Ltd., a world leader in drug research, is a fast growing, dynamic, Irish company with subsidiaries in the United States, U.K., Switzerland and Japan. Our clients include many major pharmaceutical companies throughout the world. Due to continuing expansion we now require Clinical Project Managers.

Ideal candidates should have medical or science qualifications with proven ability to establish and conduct clinical trails to meet with international regulatory requirements. The successful applicant will be based in Dublin but must be prepared to travel. Language skills and computer literacy would be an advantage.

Curriculum Vitae, which will be treated in the strictest confidence, should be submitted to:

ICP

Director of Personnel,
Institute of Clinical Pharmacology,
Sir Patrick Dun's Hospital,
Dublin 2.

ICP Joint venture HCA (8253)A

POSTDOCTORAL POSITION

ailable immediately to join a research am working on molecular approaches study viral diseases. Experience in ochemistry, molecular biology or cell ology required. Salary commensurate ith qualifications and experience. cellent fringe benefits. Send curric- um vitae, a brief summary of research terests, and three letters of reference **: Dr. Beatriz G.T. Pogo, Box 1061, The ount Sinai School of Medicine, epartment of Neoplastic Diseases, One ustave L. Levy Place, New York, Y 10029-6574.**

(NW3239)A

PROTEIN CRYSTALLOGRAPHY AND STRUCTURAL CELL BIOLOGY

Applications are invited for a **post-doctoral position** involving application of these disciplines in an on-going x-ray crystallographic study of a number of actin-binding proteins, including profilin, involved in the cytoskeleton and cell motility. The position is sponsored jointly by Drs. Thomas D. Pollard and Eaton Lattman at the Johns Hopkins University School of Medicine. Membership in the newly established Institute for Biophysical Research on Macromolecular Assemblies may be possible. Experience in at least one of these areas is preferred, but persons with experience in physics or protein chemistry and an interest in moving into biophysics are also encouraged to apply. The position is available in the spring for a period of 2 to 3 years. Salary $18,000-$20,000 depending on experience. Please contact either **Dr. Thomas D. Pollard, Department of Cell Biology and Anatomy, Johns Hopkins Medical School, Baltimore, MD 21205-2185, (telephone 301-955-5664), or Dr. Eaton Lattman, Department of Biophysics, Johns Hopkins Medical School, Baltimore, MD 21205-2185, (telephone 301-955-1210).** Johns Hopkins is an equal opportunity, affirmative-action employer. Applications from minorities or women are particularly encouraged.

(NW3241)A

University of Southern California

GRADUATE RESEARCH training positions in THE MARINE BIOLOGY RESEARCH SECTION of the Department of Biological Sciences. Students will receive Ph.D. degrees through the Department of Biological Sciences. Stipends and tuition waivers available for eligible candidates. Research areas include: at the organismal level, the biochemistry, physiology and evolution of marine bacteria, algae and invertebrates; at the ecosystem level, bacterial and plankton productivity, and community structure in polar, tropical and temperate ecosystems. Contact: **Dr. C.W. Sullivan, Marine Biology Research Section, Dept. of Biological Sciences, U.S.C., Los Angeles, CA 90089-0371.** (NW3246)A

READVERTISEMENT
BRUNEL UNIVERSITY
DEPARTMENT OF BIOLOGY AND BIOCHEMISTRY
READERSHIP IN CELL BIOLOGY

Applications are invited for a Readership in the Department of Biology and Biochemistry (Head of Department: Professor T.F. Slater) to work in the general area of cell biology/pathology.

Applicants should be established scientists with outstanding research ability. The successful candidate will play a major role in strengthening and expanding the existing Cell and Molecular Biology research group within the department. The present interests of this group include macrophage cell biology, comparative reproduction, cloning of catabolic genes, and parasite immunology. The department also has very well established research groups working on free radical biochemistry, and biochemical mechanisms of cell injury, and is well equipped for research in these areas.

It is hoped the successful candidate will be able to start on 1 July 1989 or as soon as possible thereafter. The salary will be within the Reader scale, (21,720-£24,360 inclusive of London Allowance, with USS benefits).

Further information is available from Professor T.F. Slater, and applications should be returned to the **Personnel Secretary, Brunel University, Uxbridge, UB8 3PH** by 15 March 1989. (8207)D

Post-doctoral positions

1) studying the multiple roles f EGF receptors during mouse levelopment. Techniques in- lude embryo dissection, cell ulture, recombinant DNA onstruction and transfection, mmunohistology and receptor neasurements. (2) working on he development of epithelial ayers using embryonal carci- oma cells and cell-cell and ell-matrix interactions. Send V and names of 3 referees to: **lr. Eileen Adamson, La Jolla ancer Research Foundation, 0901 N. Torrey Pines Road, La olla, CA 92037 (619) 455-6480.** OE/AA. (NW3167)A

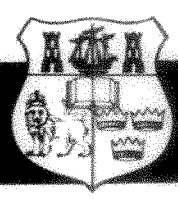
POSTDOCTORAL POSITIONS

available beginning Spring-Summer 1989, 1-3 years tenure. (1) Bioenergetic studies on mitochondria with altered membrane lipid composition and (2) Methionine metabolism by muscle and other tissues — a new pathway. Send résumé and three letters of recommendation to: **Dr. E. Jack Davis, Indiana Univ. Sch. of Medicine, Indianapolis, IN 46223.**

(NW3240)A

Applications are invited for a **College Lectureship** post in each of the following departments:

BIOCHEMISTRY
FOOD CHEMISTRY
MATHEMATICS
ZOOLOGY



Preference will be given to candidates for the post (a) in **Biochemistry** who have research experience in advanced protein chemistry or advanced enzymology, and (b) in **Zoology** who have expertise in molluscan biology and culture.

Salary scale: IR£12,488 - IR£17,063
Bar IR£18,956 - IR£24,968 p.a.

Application forms and further details may be obtained from the undersigned. Tel.010-353-21-276871, ext. 2364. Latest date for receipt of completed applications is **Friday, 24 February, 1989**

CARDIOVASCULAR RESEARCH TRAINING AT THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY PROGRAM OF EXCELLENCE IN MOLECULAR BIOLOGY

Postdoctoral Research Training Fellowships in the Molecular Biology of the Blood Vessel Wall are available for candidates with a M.D., or Ph.D. degree at a NIH-HLB, sponsored Program of Excellence in Molecular Biology of the Cardiovascular System. The twin goals of this Program are:

1) to develop an environment in which the most effective strategies of molecular biology will be employed to expand our knowledge of the function and malfunction of the cardiovascular system.

2) to train young investigators who will apply basic science approaches to the continued resolution of major unanswered questions in this area.

Our training program is designed to foster extensive interactions between the trainees and senior faculty at MIT as well as at a variety of Universities and Medical Institutions and to prepare these scientists for independent research careers.

Research opportunities are available in the laboratories of one or more of the following participating training faculty:

Robert Rosenberg	(Endothelial Cell Receptors)	Harvey Lodish	(Glucose Transporters)
Monty Krieger	(Genetic Analysis of Acetyl-LDL Receptors & Foam Cells)	Rudolf Jaenish	(Collagen and Cardiovascular Structure/Function)
David Housman	(Genetic Predisposition to Cardiovascular Disease)	Richard Mulligan	(Genetic Therapy of Hyperlipidemia)
Richard Hynes	(Fibronectin and Cardiovascular structure/function)	Earl Ruley	(Oncogene Induced Lipogenesis)

Interested candidates should send a resume indicating any preference in possible mentors to:

Robert D. Rosenberg, Program Director, Program of Excellence in Molecular Biology of the Cardiovascular System
Massachusetts Institute of Technology, Department of Biology
77 Massachusetts Ave., Cambridge, MA 02139. Telephone 617 253 8804

M.I.T. is an affirmative action/Equal Opportunity Employer (NW2823)E

UNIVERSITY OF GLASGOW DEPARTMENT OF BIOCHEMISTRY POSTDOCTORAL FELLOWSHIP

Applications are invited for an SERC Postdoctoral Fellowship, for which funding is available for 2 years, (1a scale, starting salary according to age and experience) to investigate the origins, structure and function of protein X, a recently-discovered component of eukaryotic pyruvate dehydrogenase multienzyme complex. The project will involve comparative sequence analysis of the human protein X and lipoate acetyltransferase (E2) genes to determine the relationship between these two polypeptides. Isolated gene sequences will be employed in studies on the targeting, import and intramitochondrial assembly of the high M_r core structure of the complex.

Qualified candidates should send a detailed C.V. **as soon as possible to Dr. J.G. Lindsay, Department of Biochemistry, University of Glasgow, Glasgow, G12 8QQ (telephone 041- 339 8855 Ext. 4720) from whom further details may be obtained.** Some experience in molecular, biological, immunological and protein-chemical techniques is preferable although not essential. COMMISSION OF THE EUROPEAN COMMUNITIES

Directorate-General for Science, Research and Development

Postgraduate fellowships for Cancer Research Training

EUROPE AGAINST CANCER
In 1985 the Heads of State and the Governments of the twelve Member States of the European Community stressed the importance of launching a European programme in the fight against cancer.

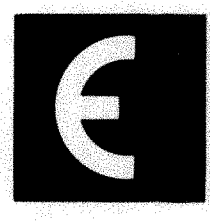
In order to implement that conclusion of the European Council, a «Europe against Cancer» programme has been prepared.

Among the areas covered by this proposal for a plan of action is Cancer Research (cancer research training, clinical treatment research, epidemiological research, early detection and diagnosis, drug development and fundamental research).

The cancer research area will be developed within the framework of the fourth Medical and Health Research Programme, 1987-1991.

PARTICIPATING STATES
Due to the great interest in the cancer problem and in the «Europe against Cancer» programme, it is expected that European non-member States may decide to participate in the fellowship scheme. The participation of Switzerland and Austria is already certain.

FELLOWSHIPS
Approximately 50 postgraduate fellowships are available each year to scientists from any participating State who wish to work for some time in a centre for fundamental, clinical or epidemiological cancer research in another participating State. The fellowships may be either long-term (one year) or short-term (one to four months). The Selection Committee may award a two-year fellowship in cases of exceptional scientific merit.



CONDITIONS OF ELIGIBILITY
- ☐ The award of fellowships is reserved to nationals of participating States.
- ☐ The research work must be carried out in a country other than the country of origin or the country of permanent residence.
- ☐ Submission of an application form and its annexes. The annexes must include a plan of research work approved by the intended host laboratory.

IMPLEMENTATION
The deadlines for applications in 1989 will be **Monday, 10 April** and **Monday, 9 October**; decisions will be taken by a panel of European Scientists in mid-June and mid-December respectively.

In general, applicants may begin work four months after a positive decision on their application.

INFORMATION
A «Guide to scientific and technical sectoral grants», including an application form, is available in all Community languages and may be obtained upon request from the address given below:

Commission of the European Communities,
Directorate-General for Science, Research and Development, (DG XII),
Division XII-H-1 «Grants» Action,
rue de la Loi 200, B-1049 BRUXELLES.
Tél: 32/2/235.39.91 or 235.40.67.

(W5789)E

BRITISH JOURNAL OF EXPERIMENTAL PATHOLOGY

FELLOWSHIP — 1989

The British Journal of Experimental Pathology offers a Fellowship in the field of experimental pathology to be awarded in the spring of 1989 and to be held for up to three years. This Fellowship is open to both medically and non-medically qualified applicants; preference will be given to applicants under the age of 40 years.

The stipend will be on the lower part of the lecturer scale and some allowance for consumables etc may also be made. The scheme is open only to applicants from institutions within the UK.

The closing date for applications is three weeks from the appearance of this advertisement. Applications should be addressed to **Professor N Woolf, Department of Histopathology, University College and Middlesex School of Medicine, The Bland-Sutton Institute, Riding House Street, London W1P 7AA.** (8177)E

NATIONAL KIDNEY RESEARCH FUND

RESEARCH FELLOWSHIPS

The National Kidney Research Fund (NKRF) is to offer two Fellowships, one clinical and one non-clinical in research areas related to renal disease. The Fellowship may be held in any suitable department in the UK. Fellows will be appointed for three years in the first instance, but an extension for a further two years will be possible. A grant of £5,000 per annum for research expenses will be available to the host department. The clinical Fellowships salary will be between £13,470 and £19,610 depending on experience. The non-clinical Fellowship salary will be at the appropriate post-doctoral level.

Closing date for receipt of applications 6th March 1989.

Application forms may be obtained from:

The Director-General, NKRF, 42 Lower Marsh, London SE1 7RG. (8099)E

CANCER RESEARCH POSTDOCTORAL FELLOWSHIPS IN MOLECULAR GENETICS, ENDOCRINOLOGY, IMMUNOLOGY, AND TUMOR BIOLOGY

The University of Rochester Cancer Center invites applications for post-doctoral positions in our research training program for 2 years beginning in 1989. The program is conducted in an integrated research and clinical setting and provides laboratory research training in a specific area of cancer research as well as a comprehensive exposure to the biology and biochemistry of cancer. Projects involve molecular cloning and structural analysis of genes related to cellular proliferation, the role of oncogenes in carcinogenesis and the molecular biology of carcinogen-activating drug metabolizing enzymes, molecular mechanisms of hormonal and nutritional regulation of the expression of specific proteins, characterization of tumor antigens and applications of hybridoma technology, the design and synthesis of new agents to increase cytotoxic drug selectivity, and the evaluation of heterogeneous cell populations in tumors and their influence on responses to therapy. Please send résumé and three letters of recommendation to: **Dr. Edgar Henshaw, University of Rochester Cancer Center, 601 Elmwood Avenue, Box 704, Rochester, NY 14642.** *The University of Rochester is an Equal Opportunity/Affirmative Action Employer.*

BIOMEDICAL SCIENCES DIVISION
Postgraduate Studentships

The Biomedical Sciences Division expects to have a number of PhD studentships available from Research Councils and Medical Research Charities in the general areas of Anatomy, Pharmacology, Physiology, Cell Biology and Human Biology.

Students who have, or expect to obtain, an Upper Second Class Honours degree or better in a relevant subject in the June 1989 examinations and who are interested in these studentships should contact **Professor S L Howell, Biomedical Sciences Division, King's College, London, Campden Hill Road, London W8 7AH, for a list of potential topics and supervisors.** (8184)F

UNIVERSITY OF MANCHESTER

DEPARTMENT OF CHEMISTRY

GLAXO RESEARCH STUDENTSHIP IN SYNTHETIC ORGANIC CHEMISTRY

pplications are invited for a search studentship to work ith Professor E.J. Thomas on e total synthesis of a group of mplex biologically active acrocyclic compounds. Applitions should have, or expect to ave, at least a 2.1 honours egree in chemistry. The post is nded by Glaxo Group Reearch and the stipend will be at e postgraduate studentship vel, i.e. £3125 at present. pplications including a c.v. and e names and addresses to two ferees should be sent as soon possible to

rofessor E.J. Thomas, The epartment of Chemistry, The niversity, Manchester M13 PL, from whom further particurs may be obtained. (8218)F

CANCER RESEARCH CAMPAIGN EXPERIMENTAL CHEMOTHERAPY RESEARCH GROUP

PHARMACEUTICAL SCIENCES INSTITUTE ASTON UNIVERSITY BIRMINGHAM B4 7ET

POSTGRADUATE STUDENTSHIPS

FOUR or more PhD studentships are available in this Group, commencing in October 1989. The Group provides excellent training in methods of research, with five academics, eight postdoctoral fellows and funds in excess of £0.5 million per annum. Synthetic chemistry, molecular graphics, cell biology, molecular pharmacology, and preclinical toxicology are the main areas of interest of an integrated programme. The following project areas are open for 1989:

1. Studies of the biochemical mechanism of tumor cytokine-induced host catabolism involving characterisation of membrane signalling cascades responsible for changes in muscle protein degradation. Characterisation of the factors responsible for muscle protein degradation. Contact Dr Mike Tisdale.

2. Studies of colon carcinoma cell differentation: the role of tumor-extracellular matrix components in drug-induced differentation. The molecular biology of heat shock protein synthesis during leukemic cell differentation. Contact Dr John Hickman.

3. Studies of the modulation of protein kinase C isoforms by growth inhibitory agents. Contact Dr Andy Gescher.

4. Rational design of DNA sequence specific antitumor drugs directed to cytosine-guanine rich sequences in oncogenes. Contact Professor Malcolm Stevens.

Candidates must hold or be expecting to obtain a first or upper second class honours degree. A number of these studentships are offered at a premium level of reimbursement. For further details contact the appropriate person in each of the areas shown ENCLOSING a full curriculum vitae and the names of two academic referees by March 1st 1989.

ASTON UNIVERSITY

(8254)F

LUDWIG INSTITUTE FOR CANCER RESEARCH

MIDDLESEX HOSPITAL/UNIVERSITY COLLEGE BRANCH

PhD Studentship

The Institute is a superbly equipped Research Laboratory (Director Dr M D Waterfield) located in a newly refurbished building close to the Middlesex Hospital. There are seven groups working in the general areas of growth control and cell signalling in relation to carcinogenesis, differentiation and development. PhD Studentships are available beginning in October 1989. The group leaders and their research interests are as follows:—

PETER PARKER: the structure and function of signal transducing molecules and their role in 'normal' and neoplastic growth.

JEREMY BROCKES: molecular basis of cell patterning in limb development and regeneration.

MICHAEL WATERFIELD: structure and function of growth factors and receptors.

PAUL STROOBANT: purification and analysis of growth and differentiation factors, and their role in initiation, growth and metastasis of tumour cells.

MARK NOBLE cellular and molecular control of development, regeneration and neoplasia in the central nervous system; oncogene function and regulation of differentiation.

JIM WOODGETT: analysis of growth regulatory molecules: emphasis on regulators of oncogenes and transducers of growth factors.

PARMJIT JAT: molecular regulation of cell growth, immortalisation, transformation and senescence.

Interested students should apply as soon as possible to:

SECRETARY TO THE ADMINISTRATOR
LUDWIG INSTITUTE FOR CANCER RESEARCH
91 RIDING HOUSE STREET
LONDON W1P 8BT
Tel: 01-436 8441

(8223)F

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)

SERC CASE STUDENTSHIP IN MOLECULAR TOXICOLOGY

DEPARTMENT OF SURGERY

Applications are invited for candidates holding or expecting to obtain this summer an honours degree (at least 2/1 standard) in an appropriate discipline for a SERC funded CASE studentship in collaboration with the Central Toxicology Laboratory, ICI, Macclesfield, Cheshire (industrial collaborator, Dr John Foster).

The research project will be to study the regulation of expression of cell surface receptors in both normal and toxin-damaged hepatocytes. The project will primarily require a sound knowledge of contemporary molecular biology techniques and some practical experience in this field would be an advantage.

Applications, comprising a curriculum vitae and the names of two academic referees, should be sent to:—

Dr David Grant, Dept. Surgery, St George's Hospital Medical School Cranmer Terrace, London SW17 0RE, and from whom further details maybe obtained (01-672 9944) ext. 55590). Reference advert: 11-89. (8199)F

NATIONAL KIDNEY RESEARCH FUND

STUDENTSHIPS

The National Kidney Research Fund (NKRF) is to offer three Studentships in research areas related to renal disease. Heads of department are invited to apply for studentship allocations. Student stipends vary between £3,690 p.a. (outer London) £4,500 (London) plus approved student fees and contribution to departmental research expenses.

Closing date for receipt of application 6th March 1989.

Application forms may be obtained from:

The Director-General, NKRF, 42 Lower Marsh, London SE1 7RG.

(8100)F

PATERSON INSTITUTE FOR CANCER RESEARCH
Christie Hospital & Holt Radium Institute

Cancer Research Campaign Studentships

Five postgraduate studentships will be available in the Paterson Institute starting 1st October 1989. These studentships are for 3 years and carry a grant from the CRC of £4,458 per annum (subject to review). The projects are:—

1. Growth factor expression by intestinal epithelial cells and the role of these factors in maintaining the stem cell niche within the intestinal crypts using both established intestinal cell lines and fractions of fresh intestinal cells enriched for crypt and villus cells. Supervisors Dr G.S. Evans (Epithelial Biology) & Dr M. Mackett (Molecular Biology).
2. Cloning and expression of eukaryotic and viral genes involved in DNA repair, using recombinant DNA technology, gene transfection, and assessment of the effect of the recombinant genes on damage caused by carcinogenic and mutagenic agents. Supervisors Dr E. Littler (Molecular Biology) & Dr G.P. Margison (Carcinogenesis).
3. Investigation of the mechanism of action of some novel anti-cancer drugs which are believed to disrupt cellular tubular function, thus providing an opportunity to study these functions in both normal and tumour cells. Applicants should have a strong interest in development of new anti-cancer drugs. Supervisors Dr A. McGown & Professor B.W. Fox (Experimental Chemotherapy).
4. Isolation and characterisation of genes encoding cell surface markers of cervical neoplasia using molecular biological techniques and functional studies on the modulation of the immune response. Supervisor Dr P.L. Stern (Immunology in collaboration with the Molecular Biology group).
5. Identification and characterisation of the growth factors, cell adhesion molecules and extracellular matrix components which are involved in cellular interactions during haemopoiesis, with particular emphasis on the regulation of stem cell growth and development. Techniques will include molecular cloning and gene expression, biochemistry and cell culture. Supervisors Professor T.M. Dexter (Haematology) Dr J. Gallagher (Medical Oncology).

The Paterson Institute for Cancer Research is a multidisciplinary research centre with all the major facilities and many research opportunities.

Applicants should have or expect to gain a first or upper second class honors degree in an appropriate subject. They should indicate which studentship(s) are of interest and submit a detailed CV including the names of two academic referees to Professor D.G. Harnden, Director, Paterson Institute for Cancer Research, Christie Hospital & Holt Radium Institute, Wilmslow Road, Manchester M20 9BX.

Closing date 24th February 1989. (8222)F

ASSISTANTSHIPS

CAMBRIDGE UNIVERSITY
Institute of Biotechnology

YEAST MOLECULAR BIOLOGY

A three year post-doctoral research assistantship is available to work on the molecular basis of gene regulation and copy number control in the yeast 2μ plasmid.

Experience in molecular biology or yeast genetics would be an advantage. Salary scale £10,460–£11,680. Earliest starting date is April 1989. Please send applications, consisting of a cv with the names of two referees and a description of research experience, as soon as possible, but in any case by 28th February 1989 to:

Dr. Jim Murray
University of Cambridge
Institute of Biotechnology
Downing Street, Cambridge CB2 3EF

Informal telephone enquiries are welcome on 0223 334754. Fax 0223 334734 (8242)P

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF CLINICAL VETERINARY MEDICINE
ANIMAL WELFARE GROUP

RSPCA RESEARCH ASSISTANTSHIP

Applications are invited for the post of Research Assistant to compile a review of stress measurements in laboratory animals. The work would be for two years. It would involve a literature survey, the evaluation of procedures and the production of guidelines. Applicants should have a Ph.D., other research experience, or veterinary or medical qualifications and should be under 26 years of age or prepared to work part-time. The salary will not be more than £10,460 per annum.

Apply enclosing curriculum vitae and the names of two referees before 28th February, 1989 to **Professor D.M. Broom, Department of Clinical Veterinary Medicine, University of Cambridge, Madingley Road, Cambridge CB3 0ES.** (8206)P

KING'S COLLEGE LONDON
DEPARTMENT OF CHEMISTRY
POSTDOCTORAL RESEARCH ASSISTANTSHIP IN NUCLEOTIDE CHEMISTRY

Applications are invited from organic chemists for a Postdoctoral Research Assistantship. The successful candidate will be required to work under the supervision of Professor C B Reese on the synthesis of oligo- and poly-nucleotides.

The Assistantship will be tenable for one year in the first instance. Salary on the 1A scale £9,865 – £11,680 per annum + £1,650 per annum London Allowance.

Applications including a **Curriculum Vitae** and the names and addresses of two referees, should be sent to: **Professor C B Reese, FRS, Department of Chemistry, King's College London, Strand, London, WC2R 2LS.**

Closing date for receipt of applications is 17th February, 1989. (8232)P

AGRICULTURAL & FOOD RESEARCH COUNCIL
Institute of Animal Physiology and Genetics Research
Cambridge

RESEARCH STUDENTSHIP
CELLULAR SIGNALLING

An MRC-funded Research Studentship, leading to a PhD in the University of Cambridge, is available starting in October 1989 to study the application of Molecular Biology to Cellular Signalling. The project, to be supervised by Dr R F Irvine in collaboration with Dr K A Wreggett in the Department of Biochemistry, is designed to study the physiology of the phosphoinositide signalling system in intact animals and cells, and will involve techniques in molecular biology. Prior technical knowledge of molecular biology or phosphoinositides is not required.

The Institute provides an excellent academic environment for research training with facilities at the leading edge of technology and currently has over 30 PhD students. Applicants should hold or expect a 1st or upper second class degree in a relevant subject. Applicants, including a curriculum vitae naming two referees, should be submitted as soon as possible to Dr R J Bicknell, Tutor for Research Students, AFRC Institute of Animal Physiology and Genetics Research, Babraham, Cambridge CB2 4AT. Informal enquiries to Drs Irvine or Wreggett are welcomed (Tel: 0223 832312). (8247)P

MEDICAL RESEARCH COUNCIL
MRC MAMMALIAN DEVELOPMENT UNIT

STUDENTSHIP

Applications are invited for three year MRC studentship starting in October 1989, an leading to a PhD degree the University of Londo The research under the supe vision of Dr Paul Burgoyn would focus on mammalian chromosome function. Appl cants should have, or expect t obtain, a good honours degre in a biological subject, prefe ably including some molecula biology and genetics.

Curriculum vitae with you daytime telephone numbe and names and addresses c two referees, should be sent t The Secretary, MRC Mamma lian Development Unit, Wol son House, 4 Stephenso Way, London NW1 2HE (tele phone 01 387 9521).

MRC
Medical Research Council

GRANTS & SCHOLARSHIPS

THE NUFFIELD FOUNDATION OLIVER BIRD FUND FOR RESEARCH INTO RHEUMATISM

Applications are invited for research grants for work directed to the better understanding, and treatment, of rheumatic disease. The Oliver Bird Fund, from which over £200,000 was spent on research grants during 1988, is administered by the Trustees of the Nuffield Foundation on the advice of an expert committee whose chairman is Dr D A J Tyrrell, CBE, FRS. The Committee is particularly interested in receiving applications from younger researchers, especially those at the early stages of their independent research careers.

Further details of how to apply are available from the Nuffield Foundation.

The closing date for applications is 31st March 1989.

Applications will be considered at a meeting in May 1989.

Grants may be made only for research in UK institutions.

Nuffield Foundation, 28 Bedford Square,
London WC1B 3EG. (8186)H

AWARDS

The Protein Society
Award Nominations Solicited

1989
THE DUPONT AWARD

This new award is for an important contribution to the study of proteins by a scientist not yet 38 years of age at the time of his or her nomination. The awardee will be honored at the 1989 Symposium of the Society by presenting a plenary lecture and receiving a prize of $6000 and a scroll. The DuPont Award is supported through the generosity of E.I. DuPont & DeNemours Co.

1990
THE STEIN & MOORE AWARD

This award of the Society recognizes contributions at the highest level to the study of proteins. The awardee will be honored at the 1990 Symposium of the Society by a session in his or her honor, and will receive a prize of $7500 and a scroll.

Deadline for nominations for either award: April 1, 1989

Please send documented nominations to:
Professor Christopher T. Walsh, Chair, Awards Committee.
Department of Biological Chemistry and Molecular Pharmacology
Harvard Medical School, 240 Longwood Av., Boston, MA 02115, USA.

SYMPOSIUM: The 1989 Symposium will be held in Seattle, WA, July 29 through August 2. The tentative program and application forms are available from **Teresa Spellman, Conference Management GH-22, University of Washington, Seattle, WA 98195, (206) 543-2300.**

WORKSHOP: A special 3D Structure Prediction Workshop is planned, at which predictions will be compared to actual structures. The Protein Society invites participation of scientists with new, as yet unpublished structures, and scientists involved in methods of structure prediction. Please contact **Dr. Douglas Rees, Molecular Biology Institute, UCLA, Los Angeles, CA 90024, USA.**
BITNET address: REES%UCLAUE.SPAN@STAR.STANFORD.EDU.

SEMINARS & SYMPOSIA

International Meeting

NITRIC OXIDE FROM L-ARGININE: A BIOREGULATORY SYSTEM

14th/15th September 1989
at The Royal Society, London, England

Evidence now emerging from various unrelated fields of research is revealing the existence of a biochemical pathway for the formation of nitric oxide from the amino acid L-arginine. This meeting will be an up-to-date discussion of the biological implications of nitric oxide formation.

Participants include:

Prof. A. Barbul (USA)
Prof. R. Furchgott (USA)
Dr. J. Garthwaite (UK)
Dr. R.M.J. Palmer (UK)
Prof. J.B. Hibbs, Jr. (USA)
Prof. M.A. Marletta (USA)
Prof. F. Murad (USA)

Attendance will be limited to 150. Prospective participants are asked to apply to the organiser for further details and abstract forms by 13th March, 1989.

Organiser:

Dr. S. Moncada, F.R.S.,
The Wellcome Research Laboratories,
Langley Court,
Beckenham, Kent BR3 3BS, U.K.
Telephone: 01-658 2211 Fax: 01-658 2278
(8172)M

The Third Symposium of
The Protein Society
will be held
July 29–August 2, 1989 in Seattle, WA

Plenary Speakers:
J. Richardson, B. Matthews, R. Huber, H. Schachman, E. Davie
Stein/Moore Symposium: H. Neurath, P. Walter, R. Jaenicke, E. Fischer

TENTATIVE PROGRAM

Protein Folding (D. Shortle, K. Dill, P. Kim)
Glycoproteins (A. Dell, A. Varki, J. Hart)
Semisynthetic Enzymes (P. Dervan, P. Schultz)
Transducing Proteins (M. Simon, C. Shutt, H. Berg)
Protein/Nucleic Acid Interaction (P. Sigler, J. Berg)
Ubiquitin, Protein Degradation (A. Hershko, J.F. Dice, A. Varshavsky)
Viral Proteins (S. Harrison, R. Hendrix, M. Rossmann)
Intracellular Structures (K. Wang, S. Brady, J. Scholey)
Chimeric Proteins (R. Lefkowitz, K. Yamamoto)
Enzyme Inhibitors (P. Bartlett, J. Kraut, D. Christianson)
RNA Recognition & Processing (J. Abelson, P. Schimmel)
Membrane Transport (G. Blobel, J. Beckwith, H. Lodish)

WORKSHOP

Predictions of 3D structures will be compared to actual structures. The Protein Society invites participation of scientists with new, as yet unpublished structures, and scientists involved in methods of structure prediction.

Please contact **Dr. Douglas Rees, Molecular Biology Institute, UCLA, Los Angeles, CA 90024, USA. BITNET address: REES%UCLAUE.SPAN@STAR.STANFORD.EDU.**

5th Annual Symposium
Molecular Biology of Hematopoiesis

University of Innsbruck, July 10-12, 1989

TOPICS:

Hematopoietic Growth Factors, Gene Transfer, Growth Factors and Stroma, Abnormal Hematopoiesis, Experimental Models of Leukemia, Gene Regulation in Hematopoiesis, Differentiation, Therapeutic Use of Hematopoietic Growth Factors.

SPEAKERS:

Abraham N, USA; Adamson J, USA; Ascensao J, USA; Bagby BC, USA; Bartram CR, FRG; Benz E, USA; Beug H, Austria; Broxmeyer H, USA; Bunn H, USA; Clark S, USA; Crowther D, UK; Eaves C, Canada; Forget B, USA; Golde D, USA; Grandchamp B, France; Grosveld F, UK; Grosveld G, Netherlands; Hoffman R, USA; Jacobs A, UK; Keller G, Austria; Koeffier P, USA; Konwalinka G, Austria; Marks P, USA; Marshall C, UK; Metcalf D, Australia; Miller A, USA; Moore M, UK; Mulligan H, USA; Naguchi T, Japan; Nicola N, Australia; Nienhuis A, USA; Orkin S, USA; Ostertag W, FRG; Peschie C, Italy; Plumb M, UK; Pragnell I, UK; Quesenberry P, USA; Raz A, USA; Sachs L, Israel; Schwartzmann M, USA; Segal G, USA; Sieff C, USA; Spooncer E, UK; Tambourin P, France; Wagner W, Austria; Wiedemann L, UK; Wright E, UK; Zanjani E, USA.

Registration Fee: US Dollars 150.00 until April 28th, 1989.
Abstract deadline: April 28th, 1989.

For program details and registration form apply to:

G. Konwalinka, Dept. Internal Med., Univ. Innsbruck, 6020 Innsbruck, Austria (Tel: 5222-504 3255)

5th FAOB CONGRESS
Seoul, Korea
August 13 – 18, 1989

The scientific program is composed of seven plenary lectures, seventeen symposia in various fields of biochemistry, colloquia, and poster sessions.

Invited speakers will include distinguished scholars from all parts of the world.

Colloquia and poster sessions are open to all participants for presentation of their research results.

BIOEXPO'89 SEOUL will be organised during the Congress. Submission of abstract is due by March 1.

For information, please contact: 5th FAOB Congress, Secretariat, c/o Korea Convention Services Ltd., K.P.O. Box 233 Seoul 110-602 Korea. Phone: 82-2-739-2141/4. Fax: 82-2-739-2145.

AACR SPECIAL CONFERENCES IN CANCER RESEARCH

Gene Expression in Cancer Cells

May 22-24, 1989, San Francisco Hilton, San Francisco, CA
Chairman: Inder M. Verma, Salk Institute, San Diego, CA

Topics: suppressor oncogenes, *muc*, EGF receptor, E1A, and cyclic-AMP regulation, *fos, jun, mos.*

Invited Speakers: Webster K. Cavenee, Mark Groudine, Joseph Schlessinger, Thomas E. Shenk, Inder M. Verma, George F. Vande Woude, Jr.

Molecular Events in Mutation and Cancer

May 21-23, 1989, Tiburon Lodge, Tiburon (Marin County), CA
Co-Chairmen:
B. Singer, University of California, Berkeley, CA
D. J. Patel, Columbia University College of Physicians and Surgeons, New York, NY

Topics: single base mismatches, O-Alkyl G and T, cyclic and bulky adducts, abasic sites and extrahelical bulges.

Invited speakers and discussion leaders: H. M. Berman, D. M. Crothers, J. M. Essigmann, M. F. Goodman, A. P. Grollman, D. Grunberger, L. H. Hurley, K. W. Kohn, S. J. Lippard, D. J. Patel, A. E. Pegg, L. Ripley, B. Singer, B. S. Strauss, J. A. Swenberg, I. Tinoco, Jr., I. B. Weinstein, R. D. Wells

Molecular Aspects of Growth Control

(Joint AACR/Japanese Cancer Association Meeting)
May 28-31, 1989, Sheraton Waikiki Hotel, Honolulu, HI
Co-Chairmen:
Enrico Mihich, Roswell Park Memorial Institute, Buffalo, NY
Takashi Sugimura, National Cancer Center, Tokyo, Japan

Topics: oncogene and cancer cell phenotypes, cytokines and regulatory factors, gene function and the carcinogenic process, control mechanisms and cancer therapeutics.

Invited speakers and discussion leaders: Ruth Sager, Hidesaburo Hanafusa, Haruo Sugano, Inder M. Verma, Charles J. Sherr, Kumao Toyoshima, Mitsuaki Yoshida, Masaaki Terada, Michel Nussenzweig, Yuichi Yamamura, Tony Hunter, William J. Rutter, Joan Massague, E. Richard Stanley, Tadatsugu Taniguchi, Tadamitsu Kishimoto, Wataru Mori, I. Bernard Weinstein, Mariano Barbacid, Frederick W. Alt, Robert A. Weinberg, Susumu Nishimura, Hirota Fujiki, Takashi Sugimura, Hiroshi Kabayashi, Ira Pastan, Yoji Ikawa, Malcolm A. S. Moore, Alexander Bloch, Takashi Tsuruo, Fuminaro Takaku, Masami Muramatsu, Enrico Mihich

The Cell Membrane and Cell Signals as Targets for Cancer Chemotherapy

(Joint AACR/BACR/EORTC [PAM] Meeting)
September 14-16, 1989. Queens' College, Cambridge, UK
Chairman: Garth Powis, Mayo Clinic and Foundation, Rochester, MN

Topics: membranes and signalling targets, physical interaction of membranes, growth factor initiated signalling, membrane lipids and signalling, ions, protein kinases and cellular differentiation, metastasis and cell death.

Invited Speakers: Jean-Pierre Abita, Wofgang Berdel, Michael Berridge Michael D. Cahalan, Dennis Chapman, David Clapham, Benjamin de Kruijff, T. Michael Dexter, Peter Downes, Janet G. Dzubow, Gordon Foulkes, Andreas Gescher, Yosef Graziani, Hans H. Grunicke, Ian R. Hart, John A. Hickman, Marc Mareel, Christopher Marshall, Edward J. Modest, Wouter Moolenaar, Harold L. Moses, Garth L. Nicolson, Ewa Ninio, Alexander Noseda, Sten Orrenius, Peter J. Parker, Garth Powis, Timothy J. Rink, Enrique Rozengurt, Thomas R. Tritton, Michael D. Waterfield.

University of York, Heslington, York, YO1 5DD, UK

ABSTRACT DEADLINE: 7 APRIL, 1989

The conference is being supported by
NOVO Research Laboratories, Denmark. LILLY, USA.
NORDISK, Denmark. (8220)C

PRACTICAL COURSE IN

IMMUNOCYTOCHEMISTRY

DATE: 18-21st JULY 1989

This four day residential course is aimed at providing knowledge and hands on experience in the preparation, sectioning, and staining of tissues using immunofluorescence, immunoenzyme, immunogold and relevant enhancement techniques. The session will include lectures from established workers in the field as well as full instruction in the interpretation of results and production of photomicrographs.

The course fee will be £330. inclusive of excellent accommodation, meals, and V.A.T. The course places are limited and early application is warranted.

CONFERENCE

The Second International Workshop on Cytokines
10 to 14 December 1989
Hilton Head, South Carolina

GOALS: a) to encompass and integrate the most recent data concerning cytokine synthesis, release, regulation, actions, and interactions, and b) to assess the in vivo effects of these cytokines on cell, tissue, organ, and organism metabolism, physiology, and immunity. TOPICS: structure, gene expression, regulation of synthesis and release, receptors and post receptor events, cytokine activities, alone and in combination, assays for and inhibitors of the cytokines. CYTOKINES TO BE CONSIDERED: the interleukins, the interferons, TNF, TGF, PDGF, chemotactic factors, the various colony stimulating factors, bone and connective tissue growth factors, as well as newly identified activities/factors.

INVITED SPEAKERS: Robert Friedman (interferons), Tadamitsu Kishimoto (IL-6), Thomas Maciag (ECGF), Lloyd Old (TNF), Russell Ross (PDGF), Ruth Sager (GRO), Arthur Silverstein (historical perspective). The content of the rest of the meeting will be based on submitted abstracts.

Abstracts will be published in the premiere issue of CYTOKINE (W B Saunders Company). Deadline for receipt of abstracts is 15 June 1989. For abstract forms, meeting information, and registration forms contact: **Sherwood M. Reichard, Cytokines, c/o RES Society, Box 3044 MCG, Augusta, GA 30912 USA.** (NW3168)C

University of Bristol
Department of Obstetrics and Gynaecology

MSc Degree Course in 'Human Fertility and Infertility'

A one year course starting in October 1989 to train doctors and laboratory scientists to conduct modern clinical and/or laboratory practice in Reproductive Medicine. It will provide advanced tuition in reproductive biology and medicine including endocrinology, ovulation induction, seminology, artificial insemination, tubal disease and *in vitro* fertilisation, and offer practical instruction in relevant clinical and laboratory techniques.

Further details may be obtained from: **MSc Course Secretary, University Department of Obstetrics and Gynaecology, Bristol Maternity Hospital, BRISTOL BS2 8EG, UK. Telephone (0272) 215411 Ext 5293.**

Application deadline: 1 June 1989. (8244)C

Two International Conferences Organised by IBC Technical Services Ltd

THE CLINICAL IMPACT OF INTERLEUKINS

10th/11th April 1989
Royal College of Physicians, London

With the first of the interleukins fast approaching the market, research on this group of proteins is now beginning to bear fruit. This international conference will examine the clinical data accumulated to date on interleukin-2 and on interleukin-2 receptor monoclonal antibodies, and review the latest data available on the other interleukins, from IL-1 to IL-7, with a look also at IL-8, IL-9 and beyond. An international panel of speakers will assess the clinical impact each of these agents is likely to have, and also the prospects they offer for new drug development.

Chairmen and Speakers to include:

Professor T. Hamblin
Royal Victoria Hospital, Bournemouth, UK

Professor S. Meuer
Deutsches Krebsforschungszentrum Heidelberg, W. Germany

Dr. R. Fildes
Cetus Corporation, USA

Dr. C. Mawas
INSERM, France

Dr. C. Henney
Immunex Corporation, USA

Dr. R. Callard
London Institute for Child Health, UK

Professor M. Feldman
Charing Cross Sunley Research Centre, UK

Dr. J. Schrader
Biomedical Research Centre, Vancouver, Canada

Dr. S. Gillis
Immunex Corporation, USA

Dr. J. Gauldie
McMaster University, Canada

Dr. L. Aarden
Netherlands Red Cross Blood Transfusion Service

Dr. C. Sanderson
National Institute for Medical Research, UK

NEW STRATEGIES FOR DEVELOPING PSYCHOTROPIC DRUGS

24th/25th April 1989
Royal College of Physicians, London

Most of the archetypes of the psychotropic drugs in use today were discovered by serendipity in the 1950s or 1960s. Since then, modern methods of drug screening have proven to be very effective in optimising these structures, but are these methods as efficient for finding new structural archetypes? At this symposium, a wide range of international experts who are tackling psychotropic drug research from a number of different angles will present their approaches, philosophies and experiences. Discussion will cover the use and limitations of structure/activity relationships, wide-ranging receptor binding as a screening strategy, the place of phytochemistry and neuroendocrinology, and the use of simple animal models and human behavioural psychopharmacology in the search for new psychotropic drugs.

Speakers will include:

Dr. M. Briley
Pierre Fabre Medicament, France

Professor G.R. Marshall
Washington University, St. Louis, USA

Professor W.D. Ollis
University of Sheffield, UK

Dr. C. Kordon
INSERM, France

Professor B. Costall
University of Bradford, UK

Professor C.G. Wermuth
University Louis Pasteur, Strasbourg, France

Dr. S. Garrattini
Istituto di Recerche Farmacologische Mario Negri, Italy

Dr. R. Porsolt
ITEM, France

Professor D. Grahame-Smith
University of Oxford, UK

Dr. S. File
Guy's Hospital, London

PRACTICAL COURSES IN MOLECULAR BIOLOGY AT UNIVERSITY COLLEGE LONDON

Department of Biochemistry

(1) PRACTICAL INTRODUCTION TO GENETIC ENGINEERING
10 April to 14 April, 1989 (inclusive)
A one week full time practical course designed to teach the basic techniques in genetic engineering. DNA will be cloned in a multicopy plasmid vector and analysed intensively using restriction enzyme mapping, Southern hybridization, and DNA sequencing. The "hands-on" approach will enable scientists from higher education and industry, clinicians and research workers who have had no practical experience of recombinant DNA techniques to set up such techniques in their own laboratories. There will be lectures supplementing the practical work and covering other areas of molecular biology.
Course Fee £550 (exclusive of accommodation)
Numbers will be limited. Deadline for Applications: 6th March, 1989

(2) cDNA CLONING: A PRACTICAL COURSE
26 June to 30 June, 1989 (inclusive)
An intensive one-week laboratory course in the techniques of cDNA cloning. The practical course will include (a) the construction of a cDNA library in λgt 10, (b) the screening of λgt 11 libraries using both antibody and radiolabelled DNA probes, (c) detailed restriction mapping of cloned genes. In addition to the practical sessions there will be lectures discussing the methods which will allow efficient construction and screening of cDNA libraries and their application to biological, medical and biotechnological problems.
Course Fee £750 (exclusive of accommodation)
Numbers will be limited. Deadline for applications: 30th May, 1989.
Bed and breakfast accommodation can be provided for the period of either course in a local hall of residence for £84.
Write for application forms and further details to:
H.A. White, Department of Biochemistry
University College London
Gower Street, London WC1E 6BT

PROTEIN PURIFICATION COURSES

Practical Course Programme 1989
— European Consultancy —

1. **Protein Purification, Process Development, Optimization and Scaling up**
   4-day course leading to production scale chromatography (50 l columns)

2. **Automated Monoclonal Purification (Process Scale)**
   2-day course using new dedicated monoclonal purification media, software package, and instrumentation
   April 24–25; April 27–28; May 8–9; May 11–12, 1989

3. **Intensive Course on Strategies of Recombinant Protein Purification (Hands on)**
   4-day practical including process development, optimization, scale up, and analytical purity checking techniques
   May 29–June 2, 1989

THE WELLCOME TRUST • Medical Research & History •

Summer School 1989

Two intensive, post-doctoral, residential, laboratory based courses will be available:

DNA related methods in Human Genetics

Co-directors: Kay E. Davies, Anna-Maria Frischauf, William Brown.

Lecturers: Duncan Campbell, Nick Hastie, Martin Hooper, Ed. Southern, Paul Travers.

July 14-23rd, 1989 (closing date for applications, March 10th).

Molecular Parasitology

Co-directors: Murray Selkirk, Debbie Smith, Julian Crampton.

Lecturers: Stephen Beverley, John Boothroyd, Alan Fairlamb, John Scaife, Ken Stuart, David Walliker.

September 1-10th, 1989 (closing date for applications, March 31st).

Applications in the form of a **curriculum vitae** and **one-page** summary of research should be sent to:

Dr. Pelin Faik, Wellcome Laboratory for Molecular Genetics, Division of Biochemistry, UMDS, Guy's Campus, London SE1 9RT.

(8256)C

INSTITUTE OF NEUROLOGY
QUEEN SQUARE

EMBO WORKSHOP

CELLULAR AND MOLECULAR BIOLOGY OF MUSCLE DEVELOPMENT

King's College, Cambridge, England
24 - 29 September 1989

The workshop will exchange information in growth areas of muscle research. The main topics will focus on: commitment and cell lineages, cell-cell interactions, ion channels, transcriptional and post transcriptional control of muscle gene expression and molecular aspects of muscle disease.

Applicants working in the field should send a brief description of their research interests before March 1st 1989.

Applications and requests for further information should be sent to **Dr Frank S Walsh, Department of Neurochemistry, Institute of Neurology, Queen Square, London WC1N 3BG. Fax: (01) 278 5069.** (8189)V

STRUCTURAL AND CHEMICAL BASIS FOR CELL FUNCTION

A conference sponsored by the Annenberg Center for Health Sciences and the Research Institute of Scripps Clinic.

April 25-28, 1989
Rancho Mirage, California

This conference has been designed to create a forum for integrating chemistry, biophysics and cell biology. Poster session will also be available to participants.

Topics: Macromolecular Assemblies, Regulation of Gene Expression, Intracellular Transport, Signal Transduction, Motility, and Cell Surface/Membrane Channels.

Organizing Committee: N.B. Gilula (Chairperson), L. Gerace, J. Hogle, B. Huang, R. Milligan, I. Wilson, N. Unwin

Invited Participants: J. Abelson (Pasadena, CA), G. Agard (San Francisco, CA), C. Akey (England), H. Betz (FRG), H. Bourne (San Francisco, CA), D. Eisenberg (Los Angeles, CA), S. Fuller (FRG), L. Gerace (La Jolla, CA), S.C. Harrison (Cambridge, MA) T. Hunter (La Jolla, CA), S. H. Kim (Berkeley, CA), M. Kirschner (San Francisco, CA), B.H. Kretsinger (Charlottesville, VA), T. D. Pollard (Baltimore, MD), D. Rees (Los Angeles, CA), J. Sedat (San Francisco, CA), K. Simons (FRG), J. A. Spudich (Palo Alto, CA), R.B. Vallee (Worcester, MA), P. Walter (San Francisco, CA)

Registration Information: The registration fee is $125. It covers the cost of the conference, coffee breaks and a reception. For registration forms, poster session forms and additional information contact: Registration Secretary, Annenberg Center 39000 Bob Hope Drive, Rancho Mirage, California 92270 or call (800) 321-3690 National, (800) 621-7322 California, FAX 619-773-4513. NATO ADVANCED STUI INSTITUTE

MOLECULAR ASPECTS (MONOOXYGENASES AN BIOACTIVATION OF TOX COMPOUNDS

August 27–September 7, 1989
Çeşme, Izmir — TURKEY

Organized by: Emel ARI (Turkey), G. Gordon GIBS (UK), Ernest HODGS (USA), Richard M. PHILP (USA), and John B. SCHEN MAN (USA)

The Institute will emphasize following: The current knowle on chemical and physical cha terization of cytochrome P- dependent and FAD contain monooxygenases, related e ymes and of Phase II conjugat enzymes; Xenobiotics and h monal control of P-450 g expression, covalent binding reactive metabolites to mac molecules; Recent advances molecular biology of these e ymes, their topology in m branes, and their role in lip sterol, steroid, and prostan metabolism; The role of th enzymes in bioactivation of to compounds and in chemical mu genesis and carcinogenesis.

Lecturers: Muzaffer AKS (Turkey); Emel ARINÇ (T key); Claude BONFILS (Franc Hugo vanden BOSSCHE (B gium); Brian BURCHELL (U Yoshiaki FUJII-KURIYAM (Japan); G. Gordon GIBS (UK); Jan-Åke GUSTAFSS (Sweden); Ernest HODGS (USA); Eric F. JOHNSON (US David KUPFER (USA); Anth Y. H. LU (USA); Franz OES (FRG); Richard M. PHILP (USA); Walter PYERIN (FR John B. SCHENKMAN (US Robert SNYDER (USA); An STIER (FRG).

The programme will incl mainly lectures, round-table cussions, and limited number poster sessions and oral pa presentations. Approximately participants will be admitt Deadline for application and a tract (not exceeding one page 15 April 1989. Applications sho include a brief c.v. and resea interests, plus a letter of rec mendation. The applicants will informed by 15 May 1989, whet they have been accepted. A de sit of US $ 100 will then be d The total cost including half-bo and lodging (sharing) is US $ Partial financial support is a lable for some participants. S applications to Dr. Emel Ar Director of ASI, Departmen Biological Sciences, Middle E Technical University 06 Ankara, Turkey. (W578

WHERE CAN YOU GET THE KNOWLEDGE YOU NEED TO COMPETE IN AgBIOTECH IN THE NEXT DECADE?

- **The significant research**
- **The newest methods**
- **The latest products**
- **The notable experts**
- **The industry contacts**
- **The financial synergy**
- **The international perspective**

AgBIOTECH '89 features a multi-track professional seminar program that only the editors of BIO/TECHNOLOGY could produce. And it's *all-ag*, all aspects — from lab to production to marketing to regulation.

Science/Technical

You'll hear leading researchers responsible for the most significant and splendid advances in transgenic crops and genetic engineering techniques discuss their research.

Business/Regulatory

You'll hear experienced industry executives with in-the-trenches experience discuss what has worked, what is economically viable, regulation, patenting, and future development.

If you're in ag-biotech — and determined to stay competitive in the '90's — you can't afford to miss this stimulating program! REGISTER TODAY!

Special Reduced Rates For Science/Technical Forum...

	Until 2/28/89		After 2/28/89	
	Business	Science/Tech	Business	Science/Tech
PASSPORT	$595	$425	$695	$475
Single Day	$230	$160	$265	$175
NON-PROFIT PASSPORT				
Acad/Gov't	N/A	$220	N/A	$220
Student	N/A	$125	N/A	$125

Free Exhibitor Workshops

Exhibitors having new scientific data, new applications, new products, or new capabilities of established products, will be holding special exhibitor workshops — *at times that do not conflict with the scheduled seminars.*
Admission FREE to all attendees.

Hands-On Exhibit Hall

Designed as the industry's most exciting showcase, AgBIOTECH '89 will once again feature exhibits of the very latest in products, equipment, services and resources that the leading suppliers have to offer. You'll be able to see, test, and compare the leading-edge lab equipment and commercial ag-biotech products.

Exhibit Hall Hours

Tuesday, March 28 — 11 a.m. to 5 p.m.
Wednesday, March 29 — 11 a.m. to 5 p.m.
Thursday, March 30 — 11 a.m. to 3 p.m.

Poster Sessions in the Exhibit Hall

AgBIOTECH '89 will feature poster papers on the most important current topics in commercial agricultural applications of plant and animal molecular biology. Papers posted will be included in the published conference proceedings.

Networking Opportunity Booth

AgBIOTECH '89 will again feature a special information area for exploring new business opportunities. Space will be available to organizations offering business connections, financing possibilities, or professional positions as well as to those seeking such arrangements.

For fastest registration, call toll-free... (800) 243-3238 ext. 232

MAIL THIS COUPON TODAY!
Yes! I want to get the knowledge I'll need to meet the challenges — and the competition— in ag-biotech in the 1990's! Send me my FREE program brochure immediately!

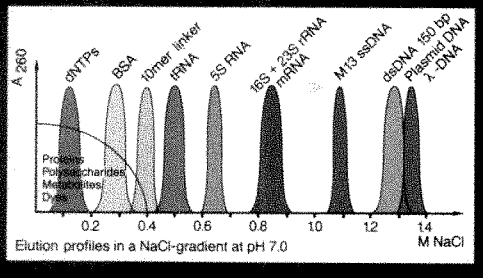
Preparing DNA?

QIAGEN



gle step purification

EN disposables transform cumbersome nucleic acid preparations into an easy, aving and inexpensive job. Picogram to ram amounts of plasmid DNA, λ-DNA, mic DNA or RNA can be directly isolated urified from cleared cell lysates in one due to QIAGENs extended separation (see fig.).

EN-tips and -packs, which fit on conven- pipettes or syringes, contain an anion- nge resin, patented to DIAGEN, for solid extraction of nucleic acids. Expensive ment such as ultracentrifuges, HPLC/ or reagents like CsCl and phenol are no required.

high purity, excellent yields and superior ical activity of nucleic acids are routinely ved in 10 minutes:

dsorb the lysate to QIAGEN.
Wash away impurities.
Elute the desired nucleic acid.

Elution profiles in a NaCl-gradient at pH 7.0

Biological activity

The quality of QIAGEN purified nucleic acids has been tested with more than 50 different restriction endonucleases, several polymerases, DNA ligases, phosphatases, kinases, and reverse transcriptases. Outstanding efficiency was obtained in all cases.

tips

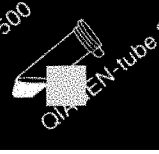
QIAGEN-tip 5 and QIAGEN-tip 20 are packed pipette tips, with a capacity of 5 20 µg of nucleic acids respectively which fi variable volume pipettes. The entire pro dure is performed simply by pipetting the propriate solution in and out.

packs

QIAGEN-pack 100 and QIAGEN-pack 500 small cartridges which fit on disposa syringes. The binding capacities are 100 500 µg of nucleic acids respectively.

tubes

QIAGEN-tube 20 is an Eppendorf™ tube c taining resin sufficient to adsorb 20 µg of h molecular weight genomic DNA (50-200 kb a simple and gentle batch procedure.



For free samples and application protoc contact DIAGEN.

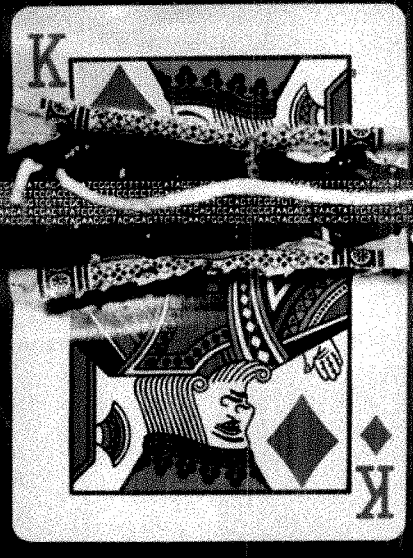
THE NUMBER 1 REASON TO CHOOSE THE ACUGEN™ PERSONAL DNA SEQUENCER™

#1. EASY TO USE:

Forget autoradiography. Forget reading autoradiograms. Sensitive beta detectors gather data from the gel as it's running and convert that data to DNA sequence. And the gel system is fast, accurate, and easier than any you've ever used.

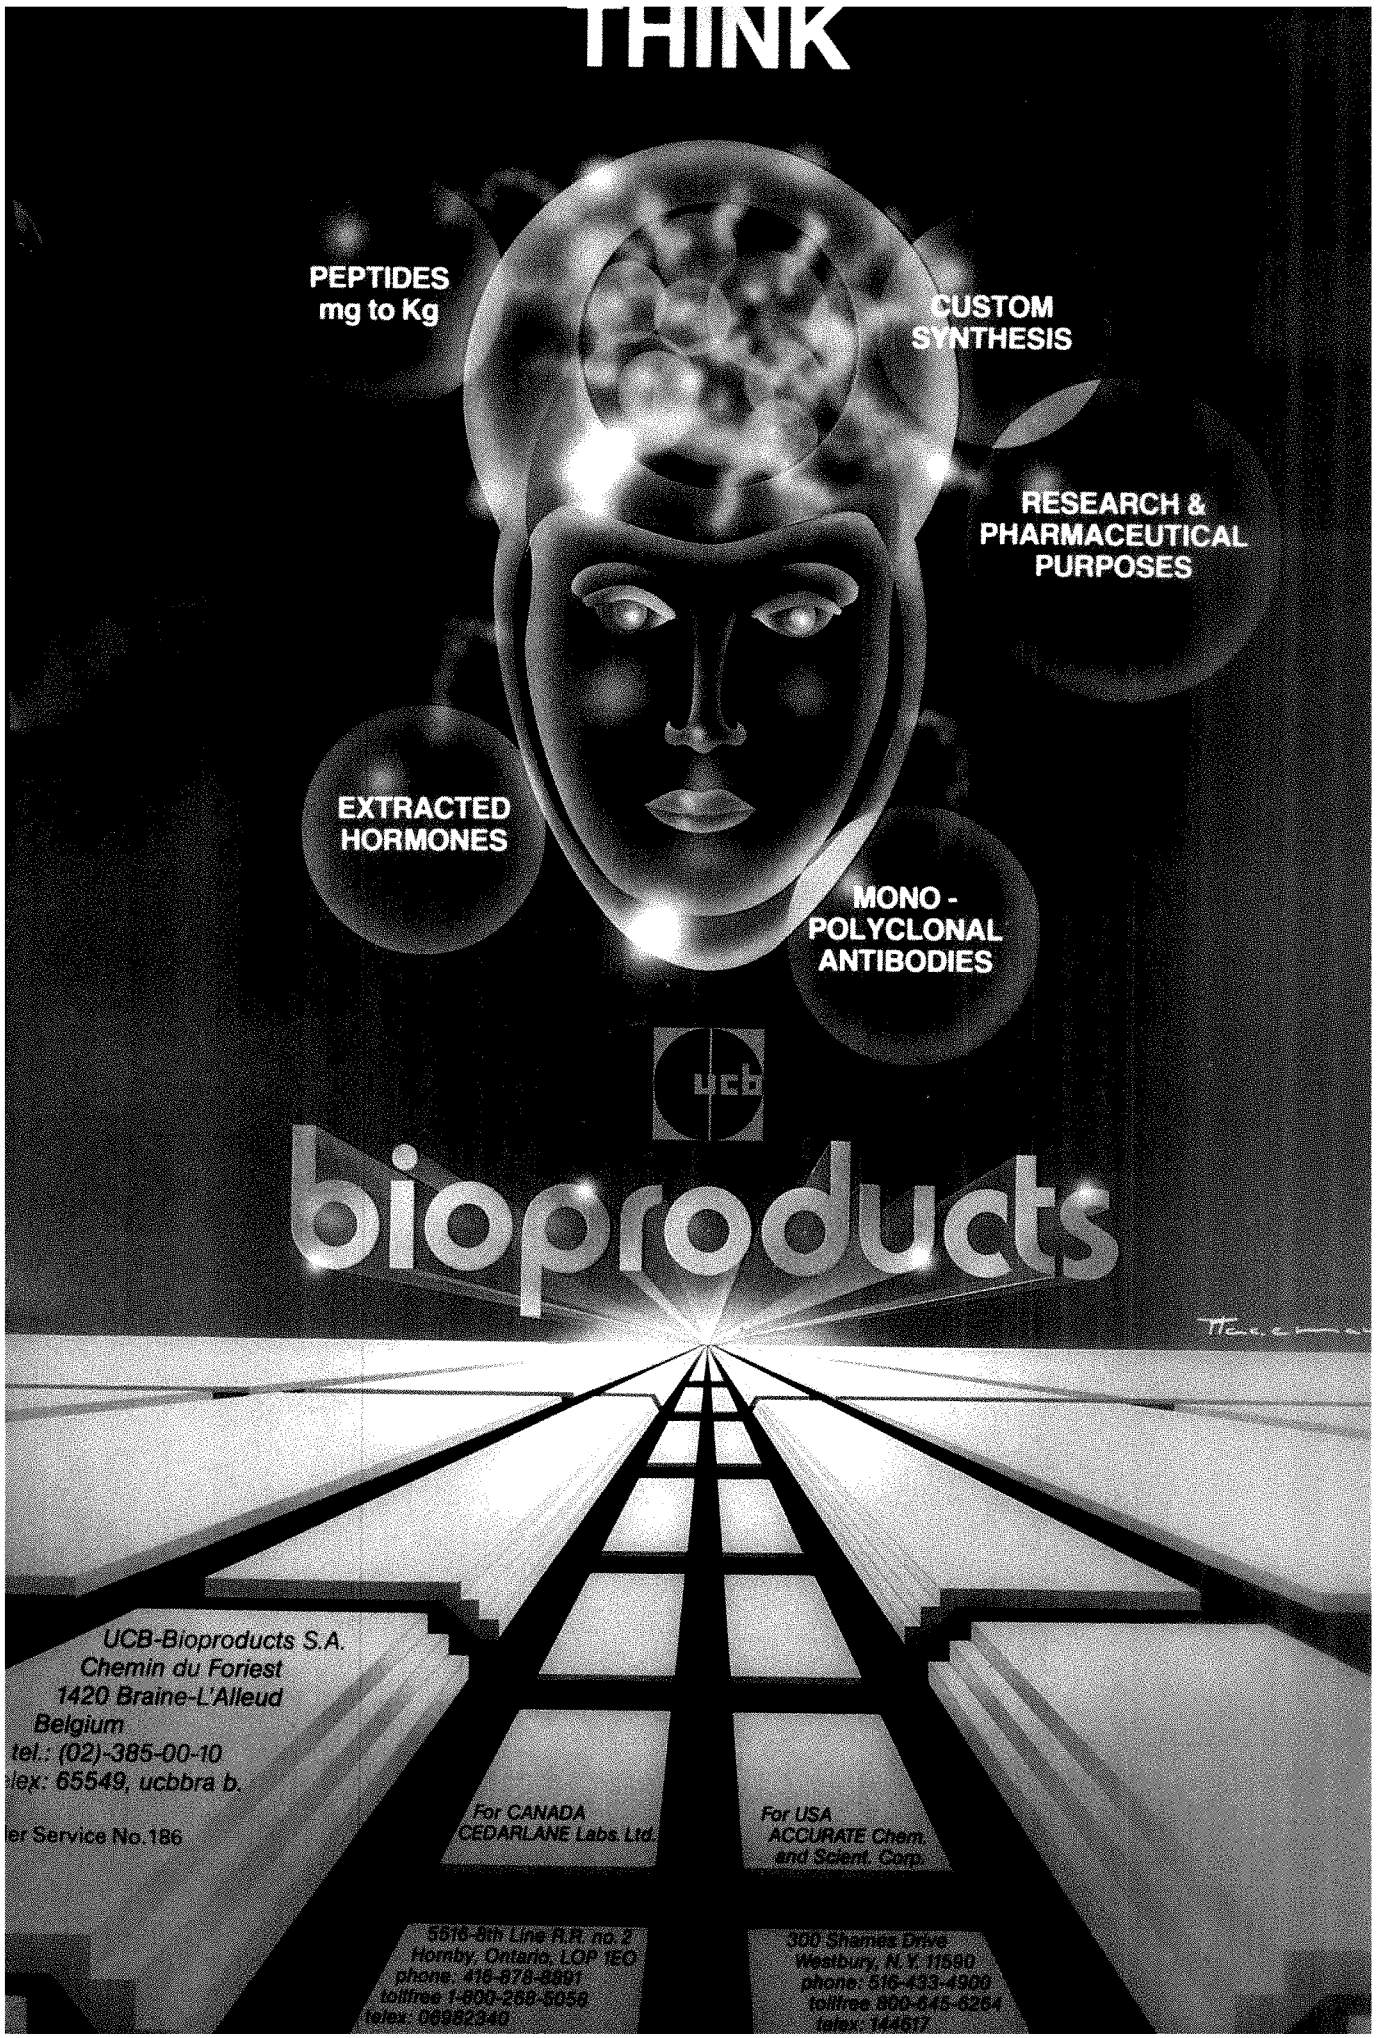
#1. AFFORDABLE:



The Acugen 402 costs less than half as much as other sequencers. So even if you're a small lab, you can afford it. And if you're a larger lab, you'll probably want to keep several running. The Acugen 402 is a personal sequencer—at a personal price.

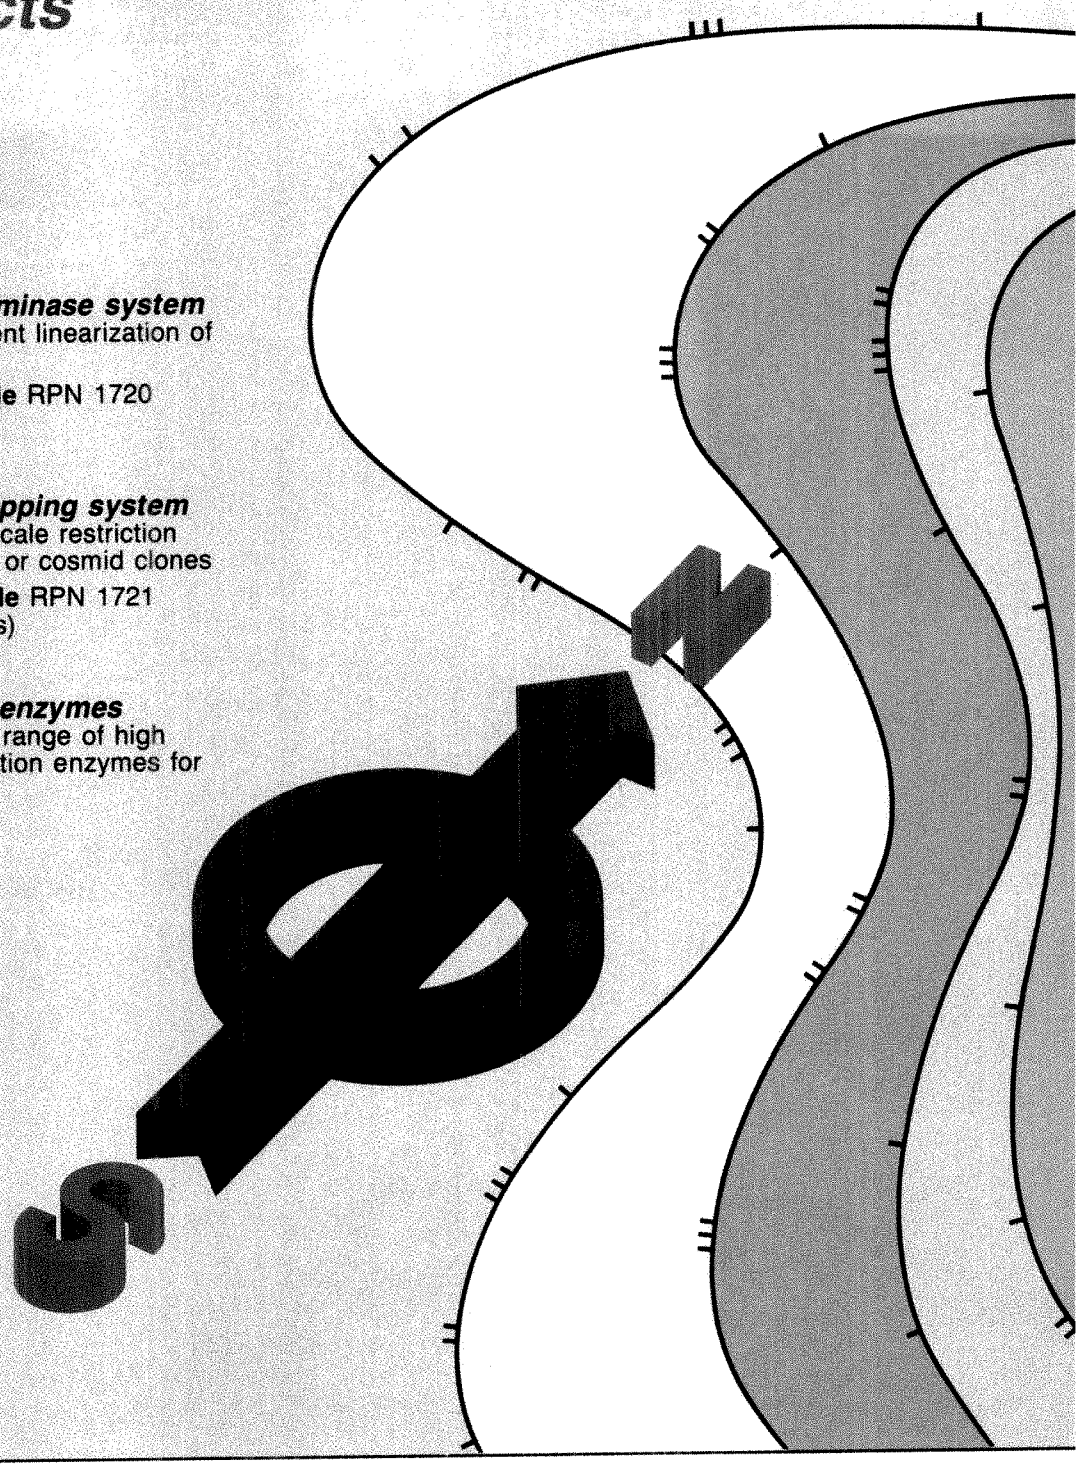
#1. ^{32}P DETECTION:

The Acugen 402 builds on success—the success of reliable, inexpensive ^{32}P reagents and standardized, widely used protocols. There are no new complicated techniques to master. All you'll have to get used to, is how fast you can generate DNA sequencing data.



#1. COMPACT:

The Acugen 402 takes up remarkably little bench space—about as much as a manual sequencing apparatus. Yet it brings you all the power of DNA sequencing automation. Big features. Small size. The Acugen 402 is the ultimate combination.



For more information or a complete in-lab demonstration of the Acugen 402 personal sequencer, call us at 1-508-650-1180. We'll show you why we're one up on every other sequencer.

Vol. 337 Issue no. 6206

The cover shows the pattern of localization of transgenic homoeoprotein Hox 1.4 in embryonic mouse gut. Mice synthesizing this protein develop a condition similar to congenital megacolon. See page 464.

THIS WEEK

Antarctic ozone

Ozone depletion in the Antarctic atmosphere above 17 km is related to the presence of chlorine monoxide, but balloon measurements made last September suggest that ozone depletion in the lower stratosphere (10–17 km altitude) is directly related to the presence of small cloud particles (0.2 micrometre radius). Page 447.

Nothing to look at

A species of 'eyeless' shrimp that lives close to hydrothermal vents of the Mid-Atlantic Ridge has a 'non-imaging' visual organ that may be a novel eye adapted to detect low-level black-body radiation emitted by the vents' hot water plumes. Pages 458, 460 and 404. In fish and toad retina, the production of mRNA for opsin is regulated by circadian oscillation and in response to light stimulation, page 454.

Strange business

Strange nuclear matter is a hypothetical substance containing approximately equal numbers of up, down and strange quarks. On page 436, ways of making it in the laboratory, and on page 434, accelerator experiments to look for naturally occurring strangeness. And see News and Views, page 405.

Proteins are versatile

Peptidyl-prolyl isomerase, an enzyme involved in protein folding, and cyclophilin, a protein that binds tightly to the immunosuppressive drug cyclosporin, are one and the same. See pages 473, 476 and 407.

A Meaning of Life?

The observation of unexpected anisotropies in the Universe is taken by some to imply a purposeful design . . . page 411.

Under cover

What lies beyond Jupiter's thick cloud cover of ammonia ice crystals? Data from Voyagers 1

and 2 point to the existence of a deeply rooted atmospheric circulation, page 444.

Segmented systems

The use of novel stains reveals regions of the developing brain in chicks with segmental organization like the patterns seen in insect development and perhaps with similar significance in morphogenesis, page 424. Parallel evidence in the mouse is provided by the expression in alternate neuromeres of a zinc-finger gene, page 461.

New phase

A new smectic liquid crystalline phase, in which the molecules are arranged in layers that are free to glide over each other, has, remarkably, both layer and helical order. See page 449.

KNAUER
SCIENTIFIC INSTRUMENTS

New Standards in Protein Chemistry

NEW: KNAUER Amino Acid Analyzer Model 830
The KNAUER Amino Acid Analyzer determines the free amino acids in physiological samples and the amino acid composition of protein hydrolyzates.

★ Fast, sensitive analyses
★ High reproducibility
★ A system designed for solving many problems:
— For amino acid reactions with fluorescence detection, e.g. with OPA and FMOC
— With precolumn derivatization
— Also suitable for other temperature-dependent reactions (up to 99 °C)
— Automatic multi-extraction of by-products
★ High efficiency at reasonable prices

Further KNAUER instruments for protein chemistry:
Modular Protein Sequencer 810
Complete HPLC and Columns
For additional information and applications:
Dr Herbert Knauer KG
Heuchelheimer Str. 9, D6380 Bad Homburg
Phone (06172) 35064, Fax (06172) 31768
Sales Representative:

DNA PROBES

(From the people who gave you Designer Genes™)

Human Interleukin 1∝

IL-1∝ is one of the two major forms of IL-1 identified. Probes are available for Exon 5, 6 and 7 of the IL-1∝ gene.

Human Interleukin 1ß

The other major form of IL-1. Probes are available for Exon 5, 6 and 7 of the interleukin 1ß gene.

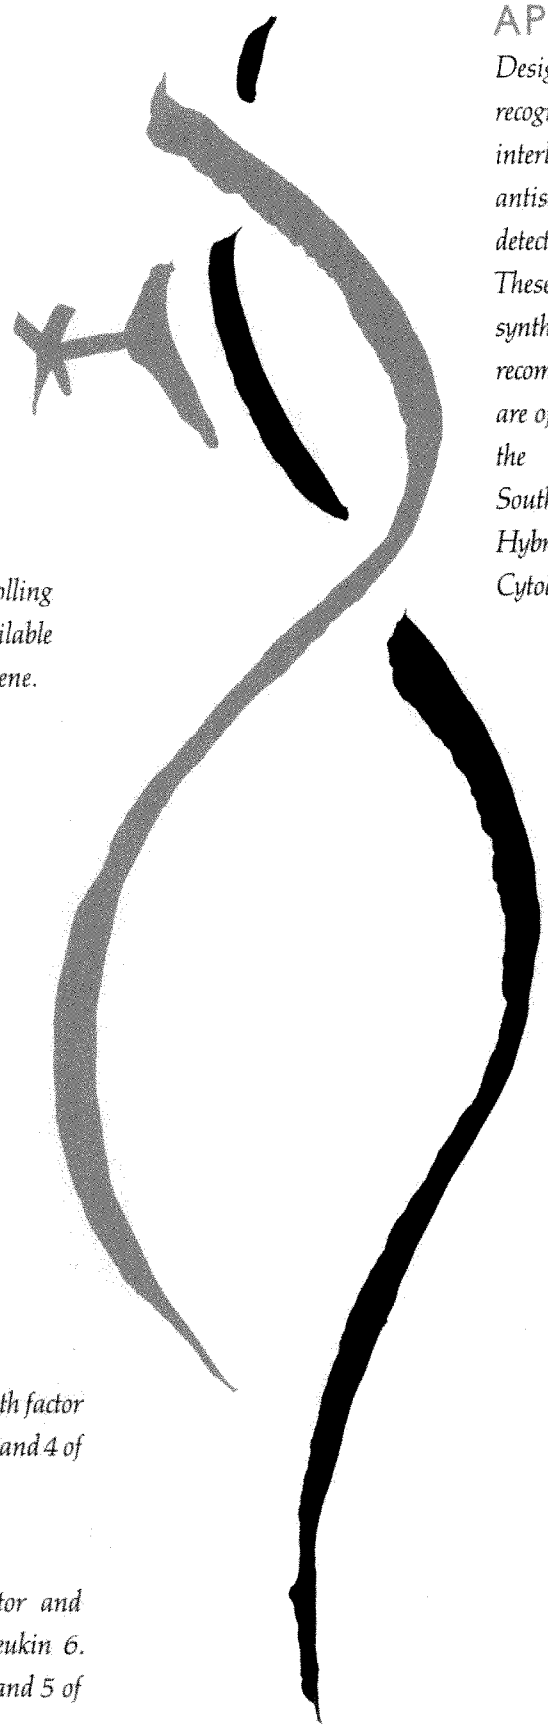
Human Interleukin 2

Interleukin 2 is a central factor controlling proliferation of T cells. Probes are available for Exon 1, 2, 3 and 4 of the IL-2 gene.

Human Interleukin 3

IL-3 is a growth and differentiation factor for multipotent erythroid and myeloid precursors. Probes are available for Exon 1, 2, 3 and 5 of the IL-3 gene.

Human Interleukin 4



With exon boundaries not yet fully defined for the IL-4 gene, probes have been designed for the 3′ region, mid-region and 5′ region of the IL-4 gene.

Human Interleukin 5

Interleukin 5 is identical to B cell growth factor II. Probes are available for Exon 1, 2, 3 and 4 of the IL-5 gene.

Human Interleukin 6

Interferonß$_2$, hybridoma growth factor and BSF-2 are now known to be interleukin 6. Probes are available for Exon 2, 3, 4 and 5 of the IL-6 gene.

APPLICATIONS

Designer Probes™ from British Bio-technology recognise certain unique exons of genes coding for interleukins. As the probes are based on the antisense sequence they are also suitable for detecting the corresponding regions in mRNA. These probes are single-stranded, chemically synthesized and supplied ready purified with recommended protocols for labelling. The probes are of defined length and Tm and are suitable for the following applications. •Northern and Southern Hybridisation •Colony & Plaque Hybridisation •In situ Hybridisation •Dot-blot & Cytodot Hybridisation.

PROBE COCKTAILS

Exon specific Designer Probes™ allow the identification of particular gene regions. The exons selected are all contained in the region coding for the mature forms of the proteins. Also available are Probe Cocktails which consist of an equimolar mixture of exon specific probes. Probe Cocktails will pick up a combination of different regions of the gene and therefore show a higher level of sensitivity than individual probes. Probe Cocktails can be used for all the applications listed above.

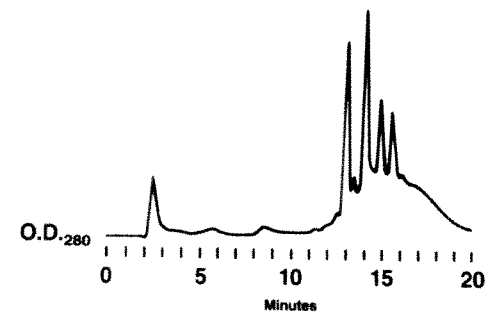
FOR MORE INFORMATION CALL OUR



Superior biomolecule purification in half the time!

Column: Preparative HRLC® MA7 Q column, 19 x 100 mm
Sample: Human lymphoblastoid extract containing human interferon α-Ly.
Flow rate: 10 ml/min
Linear flow rate: 211 cm/hr

Preparative HRLC MA7 Q column

Column: Analytical Mono® Q column, 5 x 50 mm
Sample: Human lymphoblastoid extract containing human interferon α-Ly.
Flow rate: 0.4 ml/min
Linear flow rate: 122 cm/hr

Analytical Mono Q column

For rapid, high resolution protein and nucleic acid purification, nothing equals HRLC columns from Bio-Rad. Our HRLC MA7 **non-porous** columns out-perform conventional **porous** columns by a significant margin.

What can the HRLC MA7 columns do for you?

- Rapid purification and regeneration even in preparative columns. Run times typically under 15 minutes for reduced biomolecule contact time.
- High resolution: minimal band broadening due to rapid, non-diffusion-limited kinetics.
- Easy scale-up: analytical to preparative columns using the same non-porous matrix.
- Full range of strong and weak, cation and anion exchangers.
- Excellent flow rate and chemical stability.

Compare for yourself. One chromatogram is the well known Mono Q porous type ion exchanger in an analytical column format. The other is our HRLC MA7 Q non-porous type ion exchanger in a preparative column format. Clearly, superior biomolecular purification can be yours in half the time using Bio-Rad's HRLC MA7 column chemistries.

You win both ways. Preparative HRLC MA7 columns for biomolecule purification, or analytical HRLC MA7 columns for methods development. Same superior resolution and performance—both at half the price of the competition!

Call us at 1-800-843-1412, or contact your local Bio-Rad representative to learn more about HRLC MA7 column chemistries.

Mono®Q and Mono® beads are registered trademarks of Pharmacia AB.

Comparison of HRLC MA7 beads and Mono® beads*

Parameter	HRLC MA7 beads	MONO beads
Packing material	Non-porous polymer ion exchanger	Porous polymer ion exchanger
Particle size	7 μm	10 μm
Maximum linear flow rate	600-3,000 cm/hr	300-2,100 cm/hr
pH stability	pH 2-12	pH 2-12
Pressure limit	100-200 bar	30-100 bar
Exchange kinetics	Rapid, non-diffusion limited (non-porous matrix)	Slow, diffusion limited (porous matrix)

*Based on manufacturers recommendations which vary with column dimensions.

Olympus autofocus photomicrography takes the error out of focusing

What the naked eye perceives as sharp and clear often translates into a blurred image on film or paper.

Now Olympus brings you the Vanox-S—the world's first autofocus photomicroscope system—designed to eliminate focusing error in low magnification photomicrography (objectives from 1X to 10X), and ensure needle-sharp imagery throughout the entire magnification range. All you have to do is push the AF button.

And the Vanox-S also enables the use of two 35mm cameras and a large-format camera, incorporated into the body, together with automatic exposure and four photo eyepieces. Light intensity is adjusted with neutral density filters, maintaining color temperature consistency.

The new Vanox-S research photomicroscope system lets you reproduce the actual image you see accurately and with high quality. More easily and consistently than ever before.

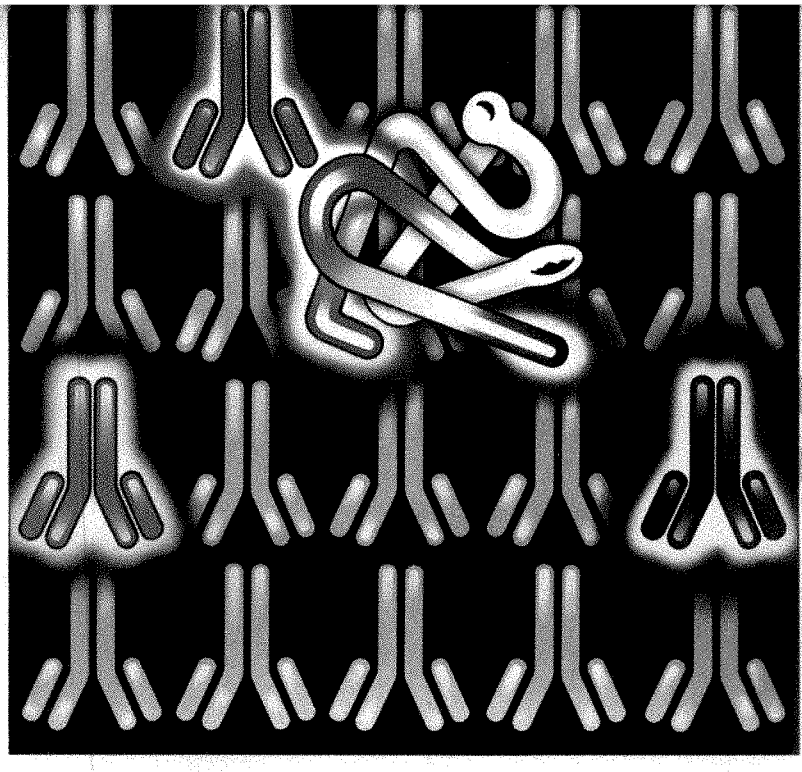
Who Offers The Extra Dimension In Peptide Technology?

Right Choice

Only Bachem has the depth of experience in peptide technology, and the selection of over 2,000 products, to assure your research stays on track.

Bachem's position of leadership has emerged from the two decades we've invested in perfecting our proprietary synthetic and purification techniques. And now this practiced discipline delivers to you unequaled purity, activity and value in every Bachem product. In fact, from synthetic peptides and intermediates to our new recombinant growth factors, we pride ourselves in knowing they are the very best.

But there's an extra dimension. Only Bachem can offer you unsurpassed scale-up capabilities whether you order milligrams or kilograms of research or bulk pharmaceutical grade peptides. Our products consistently set the standard for quality and value regardless of how complex the sequence or how fast you need custom synthesis. And the purity is guaranteed.



Start your working relationship with Bachem by requesting our catalog of peak purity products. Our knowledgeable customer service representatives stand ready to meet your product requirements quickly and efficiently. And if you have any technical questions, or require bulk price quotations we will be glad to help Remember, with all the choices you have left today, Bachem is the right one.

New oncoprotein antibodies from Cambridge

Cambridge Research Biochemicals continues to develop its range of antibodies to oncoproteins and growth factor receptors.

CRB site-specific antibody probes are raised against peptides derived from the oncoprotein sequence and are fully characterised against the native oncoprotein.

Choose from an expanding range that includes:

- NEW ● *ras* (normal and activated p21 *ras*)
- NEW ● *c-erb*B-2 (human *neu*)
- NEW ● *mos* (p37/p43 v- and c-*mos*)
- NEW ● Mouse monoclonal antibodies to *myc* family and c-*erb*B-2
- ● Control reagents
- ● *fms* (v- and c-*fms*)
- ● *fos* family
- ● c-*fos*
- ● EGF-receptor
- ● *myc* family
- ● c-*myc*
- ● N-*myc*
- ● c-*myb*

Blocking peptides are available for all antibodies. Combination kits containing antibodies, control peptides, secondary reagents and protocols are also available.

Contact us **now** for more details.

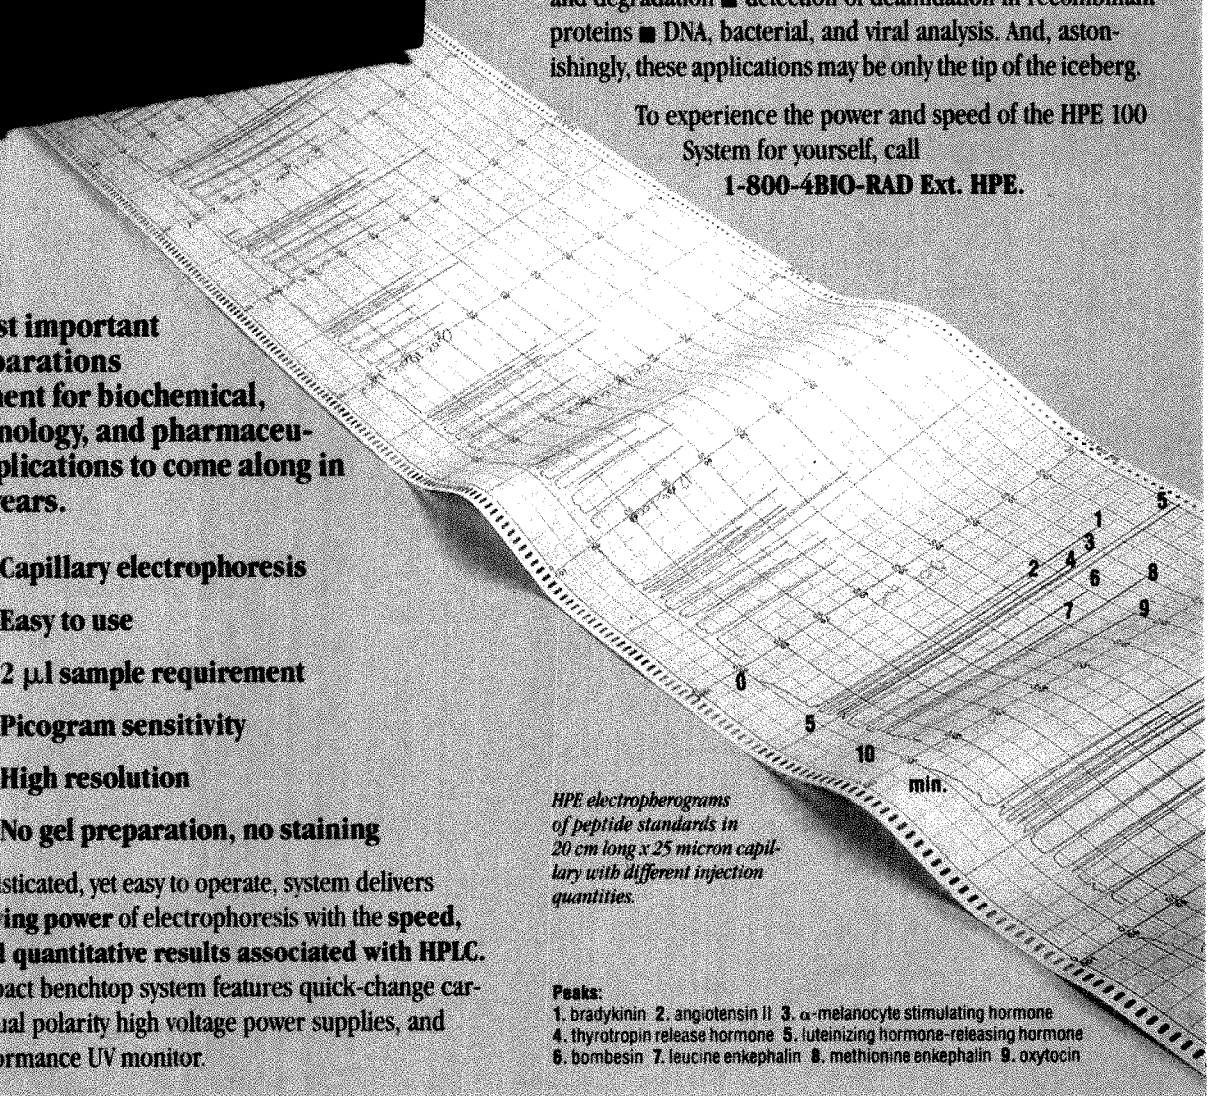
Quantitative electrophoresis in 10 minutes

Announcing the new HPE™ 100 High Performance Electrophoresis System from Bio-Rad.



Proven applications include:
■ purity checks on synthetic peptides ■ isoelectric focusing of proteins ■ pharmaceutical QC for FDA requirements ■ purity analysis of preparative HPLC ■ free zone, discontinuous or displacement electrophoresis ■ peptide fragmentation and degradation ■ detection of deamidation in recombinant proteins ■ DNA, bacterial, and viral analysis. And, astonishingly, these applications may be only the tip of the iceberg.

To experience the power and speed of the HPE 100 System for yourself, call
1-800-4BIO-RAD Ext. HPE.

The most important new separations instrument for biochemical, biotechnology, and pharmaceutical applications to come along in recent years.

- **Capillary electrophoresis**
- **Easy to use**
- **2 µl sample requirement**
- **Picogram sensitivity**
- **High resolution**
- **No gel preparation, no staining**

This sophisticated, yet easy to operate, system delivers the **resolving power** of electrophoresis with the **speed, ease, and quantitative results associated with HPLC.** This compact benchtop system features quick-change cartridges, dual polarity high voltage power supplies, and high performance UV monitor.

HPE electropherograms of peptide standards in 20 cm long x 25 micron capillary with different injection quantities.

Peaks:
1. bradykinin **2.** angiotensin II **3.** α-melanocyte stimulating hormone **4.** thyrotropin release hormone **5.** luteinizing hormone-releasing hormone **6.** bombesin **7.** leucine enkephalin **8.** methionine enkephalin **9.** oxytocin

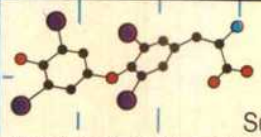
PROTEINS FROM SEQUENCES?

Chem-X Can!



Building 3-D structures of proteins from residue sequence information — one of the major challenges facing protein scientists today. Or is it? Chemical Design has taken a giant step towards a solution, using protein homology to generate 3-D models from sequences — *automatically*.

Chem-X, the world's leading molecular modelling software, now provides powerful tools for second-generation protein modelling, including:

- Advanced sequence alignment facilities
- Innovative algorithms for residue insertion, deletion and substitution (including chain repair) in regular structure and random coil
- Motif database searches
- High-speed rule-based conformational analysis
- State-of-the-art molecular dynamics, including free energy perturbation options
- Real-time modelling of ligand-protein interactions
- Outstanding display and manipulation facilities
- And much, much more...

With over five years experience in molecular modelling software development, Chemical Design has the solutions to meet real user requirements. And as user demands change and develop, Chemical Design keeps pace, offering more power, more functionality, more automated solutions.

Chemical Design's Chem-X software is already used by nearly 300 research laboratories worldwide — three times more than any other modelling system. If you already have the latest in Chemical Design software, you'll appreciate why. If not, shouldn't you find out what you're missing?

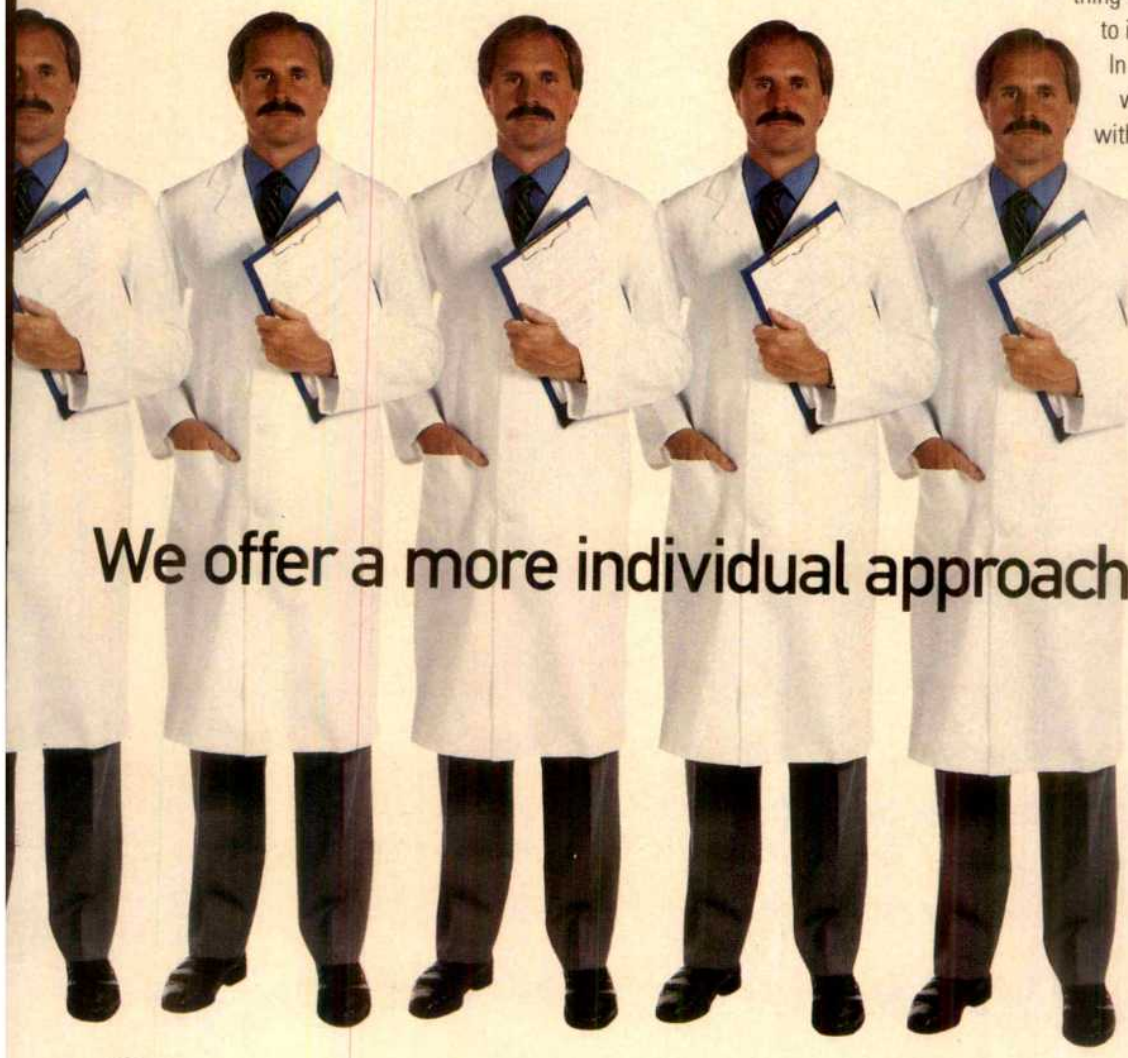
Cassette Electrophoresis System, Vertical Type

- Time saving
- Simple operation
- Superior resolution
- High reproducibility

Each component of the system is available separately.

Cassette Electrophoresis Unit "DAIICHI"

★Single, double and six gel devices for Mini Gels.
★Dual buffer tank design allows uniform heat dissipation for straight, smile-free patterns.
★IEF can be performed by attaching IEF Adaptor.(available separately)



Precast Polyacrylamide Mini Gels

★8×10 cm and 10×10 cm cassettes fit most mini gel devices.
★High resolution gradient and single percent gels with excellent reproducibility.

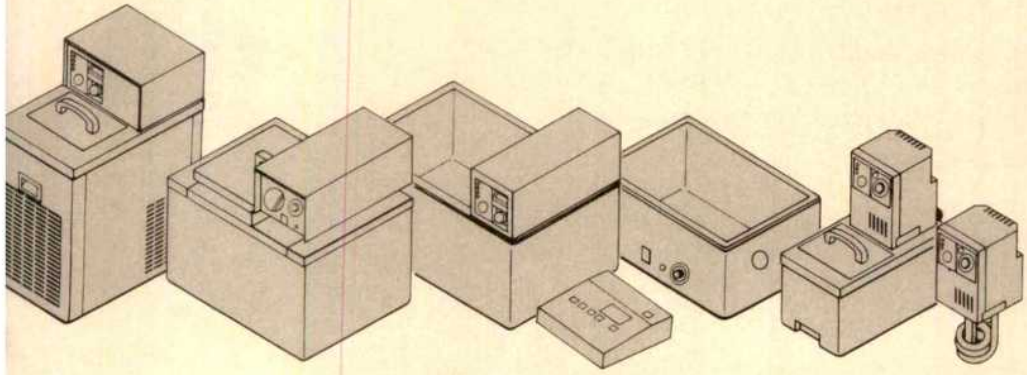
We offer a more individual approach

At Grant we recognise that our customers are not identical.

Far from it.



From the days when we designed our first water bath nearly forty years ago we realised each customer is an individual with individual requirements.

That's why we offer a comprehensive range. Yet there's one thing that is consistent: a commitmen to innovative design and reliability. In addition we provide a three yea warranty and excellent support, with over 60 distributors worldwide

So when you need good temperature control, from a simple unstirred bath to a sophisticated microprocessor-controlled circulator, choose Grant.

And enjoy a very individual experience.

- Unstirred baths
- Immersion thermostats
- Precision bath/circulators
- Low temperature bath/circulators
- High temperature baths/circulators
- Shaking water baths
- Block thermostats
- Flow heaters
- Accessories, including coolers, temperature programmer and computer control – a complete range of equipment to meet every requirement in the laboratory.

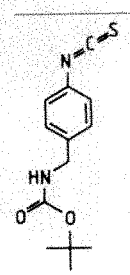
Nε-Biotinyl-L-lysine, Biocytin



$C_{16}H_{28}N_4O_4S$ M_r 372.49 [576-19-2]

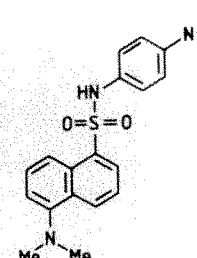
BioChemika >98% (HPLC)

mp 243–245 (dec); $[\alpha]_{546}^{20}$ +69 ±1°; $[\alpha]_{D}^{20}$ +58 ±1° (c=1 in 0.1 N NaOH)
50 mg sFr. 46.– / 250 mg sFr. 185.–

Natural substrate for biotinidase. The fluorometric assay for biotinidase uses 1,2-diacetylbenzene which reacts selectively with lysine allowing its direct determination in mixture with biocytin: H. Ebrahim, K. Dakshinamurti, Anal. Biochem. (1986) *154*, 282; used in transport studies of biotin: J. Chauhan et al., Ann. N.Y. Acad. Sci. (1985) *447*, 386; H.M. Said, R. Redha, Am. J. Physiol. (1987) *252*, G52; preparation of biocytin hydrazide, a selective label for carbohydrates in glycoconjugates: E.A. Bayer et al., Anal. Biochem. (1988) *170*, 271.

15400

4-(BOC-aminomethyl)phenyl isothiocyanate, BAMPITC



$C_{13}H_{16}N_2O_2S$ M_r 264.35 [89631-74-3]

BioChemika >98% (HPLC)

mp 111–113°; IR-spectrum: in accordance
100 mg sFr. 40.– / 500 mg sFr. 160.–

New protein sequencing reagent with a masked amino group which renders the thiohydantoin – after cleavage of the BOC protection – susceptible to fluorogenic detection, e.g. with OPA. A 2.5 to 10 fold increase in sensitivity over the most commonly used detection methods was observed: J.J. L'Italien, S.B.H. Kent, J. Chromatogr. (1984) *283*, 149; S.B.H. Kent, J.J. L'Italien, US Patent 4,548,904.

39232

4-(5-Dimethylaminonaphthalene-1-sulfonylamino)phenyl isothiocyanate, DNSAPITC

$C_{19}H_{17}N_3O_2S_2$ M_r 383.50 [102417-94-7]

BioChemika >98% (HPLC)

mp 125–128°; IR-spectrum: in accordance; luminescence: passes application test
25 mg sFr. 35.– / 100 mg sFr. 130.–

New, very sensitive Edman-type reagent for manual or automated protein sequencing in the lower picomol range: S.-W. Jin et al., FEBS Lett. (1986) *198*, 150; H. Hirano, B. Wittmann-Liebold, Biol. Chem. Hoppe-Seyler (1986) *367*, 257; J. Salnikow et al. in Methods in Protein Sequence Analysis, K.A. Walsh, ed., Humana, Clifton 1987, p. 247; H. Hirano et al., Eur. J. Biochem. (1987) *170*, 149.

27267

α-Chymotrypsin from bovine pancreas, free of low molecular weight peptide fragments (GPC)

EC 3.24.1.1 M_r ~25 000 [9004-07-3]

BioChemika 65 U/mg; lyophilized

1 U corresponds to the amount of enzyme which hydrolyzes 1 μmol Suc-$(Ala)_2$-Pro-Phe-4-NA per minute at pH 7.8 (25°C)
25 mg sFr. 22.– / 100 mg sFr. 65.–

This α-chymotrypsin is specially purified by ultrafiltration and is free of low molecular weight peptide contaminants and autolysis products.

93608

Trypsin from bovine pancreas, free of low molecular weight peptide fragments (GPC)

E.C. 3.4.21.4 M_r ~23 000 [9002-07-7]

BioChemika ~8000 U/mg; lyophilized

1 U corresponds to the amount of enzyme which increases the absorbance at 253 nm by 0.001 per minute at pH 7.6 and 25°C (N-benzoyl-L-arginine ethyl ester, FLUKA 12880, as substrate)
25 mg sFr. 18.– / 100 mg sFr. 60.–

This trypsin is specially purified by ultrafiltration and is free of low molecular weight peptide contaminants and autolysis products.

CUSTOM PEPTIDE SYNTHESIS

Using our novel synthesiser developed in house we are able to synthesise 30 peptides simultaneously. Each synthesis step is controlled thus ensuring a quality peptide. This means we can offer custom synthetic peptides:

- **with short delays**
- **at low prices**

For example:
A 15 - Mer
3 - 4 weeks delays
300 FF/residue

Contact us NOW to discuss your custom peptide requirements

London kidney exchange in trouble

British transplant physicians are in hot water for allegedly transplanting kidneys obtained by purchase. But buying kidneys may not always be wrong.

In the design of mammals, there is a useful measure of redundancy: some organs, the kidney conspicuously, appear in pairs, the redundancy being a safeguard against the stresses of long life: if one of a person's kidneys should fail, the other may be sufficient. Kidney transplants are a further safeguard. Most transplanted kidneys derive from cadavers, but because a person is not fatally or even severely damaged by the removal of one kidney, some are from living people, usually close relatives of the recipient. Nobody disputes the value of the procedure (which in Britain is believed to save £50,000 for each renal patient taken off dialysis machines). Worldwide, some tens of thousands of transplant operations are carried out each year, mostly in developed countries. (Just under 1,700 cadaver kidneys were transplanted last year in Britain alone.) The success rate is high (about 80 per cent one year after the operation, half as much ten years later).

Physiological redundancy has now also, it seems, stimulated a trade in human kidneys. For the past two weeks, London newspapers have been in pursuit of what they allege to be an international racket. There is proof that Turkish newspapers carry advertisements from would-be donors. It is alleged that a two-legged conspiracy based in Istanbul and London arranges for donors to be shipped to London for operations and, afterwards, to be paid. Some of the subsequent transplant operations are said to be carried out at London hospitals in the private sector. That makes the issue especially piquant on the eve of the publication of the government's proposals for the reorganization of its National Health Service, known to include suggestions that major hospitals in the public sector may opt for autonomy, selling medical services to the public and private sectors alike.

Legislation

If (as is probable) there is a trade in kidneys from living donors, there will also soon be vigorous demands in Britain that it should be made illegal. As things are, physicians are enjoined by professional guidelines not to take part in operations in which organs from living donors have been sold, although close relatives of a person with kidney failure may donate a kidney out of altruism. There is also a Council of Europe declaration that would outlaw the practice of transplanting organs obtained by purchase from living donors — if the declaration had legal force. But the question of whether there are circumstances in which a person may be allowed to sell a kidney of his or her own for cash is more complicated than it may seem.

Operationally, the underlying principles are clear, even simple. Physicians with patients in need of a kidney transplant naturally owe their first duty to them, but are not thereby ethically absolved from the responsibility of enquiring into the means by which kidneys for transplant are obtained. In part to protect the zealous transplant physicians from their proper zeal, it is standard practice when transplant organs are obtained from patients who have died in intensive care that an independent physician is responsible for deciding when the putative source is brain-dead. The same principles should apply with the transfer of organs from one living person to another. It should be for a physician independent of the intended recipient to shoulder ethical responsibility for the interests of the would-be donor.

Naturally, this second physician's chief responsibility (apart from seeking contra-indications to the proposed operation) must be to ensure that the intending donor is fully informed of the consequences, which are not as innocuous as the notion that one kidney is redundant would suggest. In normal people, kidney function becomes less efficient in middle life, and then progressively declines. However healthy a young donor may appear, losing a kidney must increase the risk of illness or even death in the second half of the normal lifespan. It is crucial to an understanding of what has been happening in London to know whether the Turkish donors so far tracked down were made fully aware of these extra risks. In principle, they might have been partly compensated by some form of health insurance, but there has so far been no suggestion of such arrangements. Indeed, the physicians most obviously concerned in the protection of the donors' interests have been singularly uncommunicative so far, yet they are those who shoulder the chief ethical responsibility.

With these provisos, there are two reasons why the practice of rewarding kidney donors even with sums of money large enough to provide an incentive should not be unthinkingly banned. First, there may be circumstances in which the balance of a potential donor's interests suggest that cash now justifies the risk of ill-health later. The simplest version of the hippocratic doctrine that no physician shall ever act so as to hazard a patient's health is easily challenged. What if the intending donor needs cash to care properly for a handicapped child, for example? Is the altruism that justifies the transfer of organs between relatives never transferrable to third parties? Even when there will be two beneficiaries (the recipient of the kidney and the object of the displaced altruism), not just one? It goes without saying that physicians will not win the freedom to use this or other possible shadings of hippocratic principles unless they are not merely willing, but eager, to describe and explain their conduct towards donors publicly — and to demonstrate that their own rewards are seemly. No doubt the medical profession's regulators will act with appropriate severity if these explanations do not emerge from the inquiries now under way in London.

The second reason why it is unwise to attempt to ban these practices is that the law is unlikely to be effective. Physicians where medical practice is relatively advanced inevitably attract patients from elsewhere. But the demand for kidney transplants is understandably so clamant that the trade (if there is one) will, if banned, shift to less squeamish places where standards of practice and (usually) ethics are high. Can that be to the greater good? Much the better way of blunting the problem is to ensure that the supply of organs for transplant is sufficient. In Britain, the National Transplantation Tissue Service, which operates within the public health service, is now able to meet only two-thirds of the demand for kidneys. British private-sector medicine derives a few dozen kidneys a year from dwindling unmatched supplies from the United States, but otherwise relies on living donors. Yet the shortfall is not so great, and might be made good by better international arrangements for collecting, matching and delivering kidneys to where people need them. That, not legislation, is the way out of this dilemma. □

Japan's science budget expands

- Spending reflects role as world power
- Massive budgets for space and nuclear power
- More money for superconductors and AIDS

Tokyo

JAPAN's cabinet last week finally approved an expansionary ¥60.41 million million budget for fiscal year 1989. The budget is late, delayed by battles over the introduction of a new sales tax and by the resignation of three cabinet members who have admitted involvement in the Recruit stock scandal. But even with public confidence in the government at a new low, the economy is untroubled; a predicted 4 per cent growth rate lies behind the decision to let the budget rise 6.6 per cent over 1988.

Big increases in defence, overseas development assistance and student exchanges mark Japan's increasing awareness of its role as a world power. Science and technology budgets are also characterized by the appearance of new programmes to aid in the internationalization of Japan's research system, in line with the Council for Science and Technology's guidelines to emphasize international contributions and creative research and development in 1989.

All the international programmes are still tiny in financial terms, and despite the guidelines many had to be rescued at the very last minute from a hard-hearted Ministry of Finance. Even the Human Frontiers Science Program had to struggle for survival but it is finally under way, more than three years after first being proposed, with a budget of ¥2,400 million ($19 million) split between the Science and Technology Agency (STA) and the Ministry of International Trade and Industry (MITI). The programme is intended to promote basic biological research through international cooperation (see *Nature* **334**, 281; 1988) and will have its headquarters in Europe. London is the favoured location but Paris, Brussels or Heidelberg are still possibilities.

Both STA and MITI will also set up new organizations to look after foreigners coming to work at their research institutes. Problems of language, culture and accommodation have so far been left to each institute to solve (or abandon) in its own way. Increasing numbers of foreigners should be on their way to Japan, with the budget granting extra fellowships for scientists from the seven summit nations at STA and the Ministry of Education, Science and Culture (MESC). But filling those places already available remains a problem (see *Nature* **335**, 287; 22 September 1988).

Within STA, budget increases go to both the International Frontier Research System and Exploratory Research for Advanced Technology (ERATO) programmes. Both have been specially designed to break down the hierarchical structure of Japan's research laboratories and to involve foreign researchers. B the really massive budgets go to spac where development of the H-II rocket under way, to ocean research, where t Shinkai 6500 submersible has just be launched (see page xxx), and to nucle power, where a special account provid large sums for studies of nuclear pow plant safety. Opposition to nuclear ener is now increasing in Japan at a runaw pace. Earth science expenditure al booms with the launch of the Mari Observation satellite (MOS-1b) due f 1989, followed by the Earth Resourc Satellite ERS-1 in 1991.

Expenditure at TRISTAN comes dow (but running time goes up) as constructio of the electron–positron collider is com pleted. Spending is also down on ocea sciences as the construction of the ne oceanographic research vessel *Haku maru* nears completion. Big increases a given to nuclear fusion research, to co struct the world's biggest helical fusio device near Nagoya, and in space researc to prepare for the 1990 launch of MUSES 1, a test satellite which will attempt t swing-by the Moon.

Both MITI and the Environmer Agency join in international concern ove global environmental problems, MITI wi a initial 'concept' for a major project an the Environment Agency with a budget t develop an ozone monitoring device to fl on the Advanced Earth Observing Sate lite 1993. The Environment Agency als receives funds to monitor acid rain and t put on showcase international enviro ment conference in Tokyo.

International trends are also reflecte in the predicted big budgets for researc on superconductors, both high-tempera ture and conventional, at STA, MIT and MESC, and in increases for AID research by the Ministry of Health an Welfare (see *Nature* **335**, 194; 15 Septem ber 1988) even though the number o AIDS cases remains very small.

Both MITI and the Ministry of Trans port are also looking at projects to tunne beneath Tokyo at depths greater than 5 metres, beyond where landowners' right end. Land prices are now so high tha Tokyo could (in theory) be mortgaged fo sufficient money to buy all the private lan in the United States plus all the companie quoted on the US stock exchange (th transaction is not practical, althoug Japanese politicians like to joke abou buying something smaller, California fo example). The Ministry of Transport i interested in deep subways; MITI has a more futuristic plan to put factories i caves deep underground where even foreigners may be able to afford the rent.

Alun Anderson

Details of the Japanese science budget

	1989 ¥000 million	% change from 1988
Human Frontier Science Program	2.4	—
Science and Technology Agency		
Space	108.9	+10.6
Nuclear energy	279.9	+3.1
Ocean research	10.5	+11.1
Earth sciences	30.4	+72.0
ERATO	4.5	+18.4
International Frontiers	1.8	+11.8
Ministry of Education, Science and Technology		
Research grants	51.8	+6.6
Fellowships	1.9	+27.1
Accelerator physics	15.5	−6.1
Space science	21.0	+6.1
Nuclear fusion	9.2	+21.4
Marine science	2.9	−46.7
Ministry of International Trade and Industry		
New Energy and Industrial Technology Development Organization	7.2	+64.1
Basic technologies for future industries	6.8	+7.2

Moonlight project	10.5	+7.3
Fifth-generation computer	6.4	+12.5

UK universities request £183m

London

BRITISH university vice-chancellors last week asked the government for an extra £183 million over the next two years to help recruit and retain high quality staff and put an end to the pay dispute with academics, now into its fourth week.

The Committee of Vice-Chancellors and Principals (CVCP), asked for £64 million for 1989–90 and £119 million for 1990–91. This would finance a 6 per cent pay rise for all academic staff and leave some extra money to raise salaries in areas where there is a staff shortage and to reward staff of outstanding merit.

Academic salaries have fallen by more than 20 per cent relative to average earnings since 1979, said Richmond, in a letter to Kenneth Baker, the Secretary of State for Education. The CVCP has already offered staff a 3.5 per cent pay increase for this year but it recognizes that this is inadequate. If this offer cannot be improved, salaries will fall by a further 5–6 per cent in 1989, says Richmond, and to pay competitive salaries, numbers will have to be cut. The Association of University Teachers (AUT) has criticized the CVCP request, pointing out that even if this money is forthcoming, pay will still be 20 per cent behind average earnings relative to 1979 levels. It demands a substantial increase in basic pay levels, not just rewards to certain groups and individuals.

A survey for the CVCP has shown that 36 per cent of professorial posts and 19 per cent of lectureships were vacant last year. Recruitment of professors was particularly difficult in mathematics, accountancy, electrical engineering and computing. For lecturers, it was also difficult in general science, engineering and business studies.

The CVCP wants to add three discretionary salary points to the top of the lecturer pay scale to avoid having to promote to senior lecturer, which it says is unnecessarily expensive.

The committee also asked for £28 million for payment of overheads on research contracts. Because earnings from research councils and charities have increased, the University Grants Committee can no longer comply with its own instruction that universities should receive 40 per cent in overheads on research contracts, said Richmond. It also wants to increase technicians' salaries. In 1986, they were paid 18 per cent below market rates, and by April this shortfall will be 27 per cent.

The AUT boycott continues to disrupt examinations throughout the country; mid-sessional examinations are being cancelled and papers for summer examinations are not being set.

Christine McGourty

West German biochemistry institute set ablaze by "viruses"

Munich

MOLECULAR biologists in West Germany have been sleeping uneasily since 2 January, when arsonists broke into a laboratory in Darmstadt and started a fire that caused damage estimated at DM1.5 million.

Authorities say that the early-morning attack on the biochemistry institute of the Technische Hochschule in Darmstadt was the work of an 'autonomous' group thought to be loosely affiliated with the terrorist Red Army Faction. Because of the possible terrorist connection, the case is being investigated by the federal prosecutor-general. The only clue to the identity of the criminals is a letter, postmarked in Frankfurt, that was sent to news organizations.

In the letter, the "angry viruses" (*zornige Viren*) — a previously unknown group — take responsibility for the attack. The letter, written in a convoluted style, calls genetic engineering a tool of Western imperialism used to exploit the developing world. The use of such techniques in agriculture, says the letter, is directly related to the "programmed starvation" of subsistence farmers. Human genetics and reproductive technologies are the "definitive attempt" to subject the fertility of women to masculine exploitation and control.

The director of the biochemistry institute, H. G. Gassen, is singled out in the letter as a "clever propagandist of genetic engineering". Gassen had become known locally as the initiator of a university–industry consortium for pharmaceutical research. The letter accuses Gassen of trying to increase public acceptance of genetic engineering by acknowledging specific criticisms but defending the research in general.

The attack is the latest in a series of assaults on research institutes and private companies that use molecular biology techniques. Earlier attacks have been reported in West Berlin, Cologne, Braunschweig, Münster, Hannover and Heidelberg.

The West German press and the public have expressed strong reservations about genetic engineering in recent years. West German police have alerted other private and public research institutes of the danger of a possible repeat attack.

Gassen, whose work involves the development of synthetic enzymes for diagnostic purposes, says he will not let himself be intimidated by the attackers. "That's just what they want — for us to perform our research in secret behind locked doors. We refuse to play their game." The fires were set in four places on the sixth floor of the biochemistry institute using bags of gasoline hooked to a welding kit and a timing device. Gassen's isotope laboratory was left coated with soot and will be unusable for at least three months.

The fire would have endangered "ten years of research", says Gassen, but it was extinguished by the fire department before it could do more damage.

Seasonal greetings at high dilution

THE Department of Pharmacology at the Free University of Amsterdam follows the practice of commissioning a solsticial greetings card from its two newest members. This year's card is reproduced above. □

New warmth via research scheme

Tokyo

THE first meeting last month of the Joint High-Level Advisory Panel set up under the new US–Japan Science and Technology Agreement focused on problems of 'comparable access to common base technology' in Tokyo. But Japanese representatives also expressed interest in participation in research on global environmental change, a new area for Japan.

According to officials at Japan's Foreign Ministry, Prime Minister Noboru Takeshita has been advised that Japanese participation in research on the greenhouse effect and acid rain would be well received in the United States. Takeshita intends to host a conference on global environmental problems in Tokyo this year and may propose a joint US–Japan research programme when he visits Washington next month.

The fourteen members of the advisory panel include Deborah Wince-Smith, assistant director of the US Office of Science and Technology Policy, Mary Good, chair of the US National Science Board, and Robert White, president of the US National Academy of Engineering. Among the Japanese members are Michio Okamoto, former president of Kyoto University, Saburo Nagakura, president of the Graduate University of Advanced Studies, and Minoru Oda, president of the Institute of Physical and Chemical Research. Wince-Smith said that discussions had been "free" and "very positive" and that the group did not try to "revisit" the issues that made negotiation of the US–Japan agreement long and difficult. But several Japanese participants noted that the problem of "comparable access" was not easy to solve quickly.

Both nations would like to see equal access to each other's research at the 'generic' or 'pre-competitive' stage, that comes before 'applied research' generates actual products. The problem is that whereas US base technology is often developed in government laboratories, to which foreign researchers have access, much Japanese technology is developed in private companies closed to outsiders. The US government has considerable leverage even over research performed in private laboratories, as much of it is paid for by the Department of Defense funds. The same is not true in Japan.

Japanese panel members stressed that progress towards putting foreign researchers in company laboratories is likely to be slow, and that much discussion is needed. Some members believe the quickest way to increase joint access to basic research would be to strengthen Japan's university system. **Alun Anderson**

Foreign critics hit a nerve in self-conscious West Germany

Munich

FOREIGN researchers' eloquent criticisms of academic life and society have caused a stir in West Germany, a country unusually concerned about what foreigners think of it. The criticisms appear to have hit a raw nerve throughout the country, provoking a response of shame and self-analysis. West Germany has had to cope with a rising number of foreign workers and ethnic German 'returnees' from Eastern Europe.

The widely reported comments appear in a report (*Through the eyes of others: experiences of foreign researchers in Germany*) issued by the respected Alexander von Humboldt Foundation. The non-profit foundation brings hundreds of researchers to West Germany every year for periods up to two years. It has supported more than 12,000 foreign researchers in the past 35 years.

The negative experiences described in the report stand in sharp contrast to the generally glowing reviews received in the past. This may in part be explained by the fact that Humboldt fellows have only recently been required to fill out questionnaires about their stay in Germany. Voluntary contributions formed the basis of earlier reports issued in 1965 and in 1977.

Although the overwhelming majority of researchers felt they profited from their stay in West Germany, the criticisms attracted the most attention. Most disturbing to West Germans was the increasing xenophobia and insensitivity that the researchers encountered in West German laboratories, libraries and on the streets.

One frequently quoted account was by a black South African scholar who first came to West Germany in 1958. He wrote that in his first three-year visit he had been openly confronted with racism only once and had struck up friendships with West Germans on the street and in the labour unions where he sometimes worked, leading him to consider West Germany his "second homeland". Twenty years later, he felt "wounded" by "harsh, unpremeditated words flung at him" in the streets.

Although his experiences are more extreme than many of those described by foreign researchers, the image of "material riches" accompanied by "emotional poverty" was a common theme in their reports.

In addition to its message for West German society at large, the report included criticisms of everyday university life. Comments such as "more confrontation than cooperation" and criticisms of the hierarchical organization were commonplace, especially from West European or North American researchers. One researcher wrote that "German professors are the last German kings".

Despite the criticisms, Heinrich Pfeiffer, general secretary of the Humboldt Foundation, said that in the past eight years the foundation has been "overrun with applications" from all over the world. It is at present planning a drive to raise money so that it can offer a hundred new fellowships to researchers from China and the Soviet Union. There have been growing numbers of applications to the foundation from both countries in recent years. **Steven Dickman**

Harvard group to teach Soviet diplomats

Boston

THE Soviet Ministry of Foreign Affairs has announced that it will accept an offer by the Harvard Negotiation Project to conduct a five-day 'negotiation workshop' for mid-career Soviet diplomats in Moscow this spring.

Although bilateral cooperative efforts have lately been flourishing between the United States and the Soviet Union, negotiation skills of diplomats have not kept pace with the improved climate, according to the Negotiation Project's director Roger Fisher.

Fisher, a professor at Harvard Law School, says the new arrangement represents "a crucial, early step in the development of a needed skill", namely to learn "how to handle differences" between the two nations through diplomatic channels. The negotiation workshop will be held at the Soviet Ministry's Diplomatic Academy in Moscow, which provides advanced training for experienced Soviet diplomats.

Among Fisher's suggestions for alternative processes are "pre-negotiations" where parties sit down together to reach a mutual understanding of the scope and quality of the outcome desired through the negotiation process. Fisher calls international conflict "a growth industry", and says that improving conflict resolution procedures is necessary "in order to make the civilized world work". Now that the Soviets have agreed to a workshop, the Negotiation Project wants to persuade the State Department of the United States to accept a similar arrangement. So far, the State Department has not accepted the offer.

European molecular biology laboratory in search of a director

London

THE withdrawal of the only candidate for one of Europe's top scientific posts has created a considerable problem for the governing body of the European Molecular Biology Laboratory (EMBL) in Heidelberg. The most likely outcome of a meeting of EMBL's council on 6 February is that the present director, Lennart Philipson, will be asked to stay on beyond April 1990, when he was to have been replaced.

The hunt for a successor to Philipson, who has been director since 1982, has been under way for two years. A search committee chaired by the council's chairman, Professor Jan Drenth, scoured Europe for suitable candidates and identified a handful. But only one of them, Professor Tom Blundell of the Crystallography Department, Birkbeck College, London was interested. He withdrew his candidature two weeks ago after some months of negotiation.

At a council meeting last December, it became clear that a small number of the 14 countries that provide EMBL's funds were opposed to Blundell's appointment, and a decision was postponed until next week's special meeting There has been little or no weakening of the opposition and it seems unlikely that the ten votes necessary for the appointment would have been cast at the meeting.

One reason given for opposing the appointment, particularly by the French delegation, was that EMBL should not have a structural biologist as its director. But there was also opposition, much of it from within EMBL, to Blundell's condition that he should be allowed to continue his personal research, even though his proposal was for a modest group of 10 people.

Blundell says he had been greatly looking forward to the challenge of the job, and particularly the task of sorting out the central facilities of EMBL, including its out-stations and the biocomputing laboratory, whose work falls within his own expertise. Instead, he now hopes for rapid progress in his negotiations with the Imperial Cancer Research Fund for a substantial programme of collaborative research.

EMBL's council is faced with the choice of restarting its search for a successor to Philipson or extending his stay. Drenth feels that it would now be in the best interests of the laboratory if Philipson would stay on. And Philipson is believed to be willing to stay if certain conditions are met.

Peter Newmark

BMA scorns loans

London

THE British Medical Association (BMA) this week criticized the government's plans to introduce a loans system for students to supplement the current grants system, saying that students would be deterred from entering the medical profession, especially those from poorer families. The profession is disturbed at the prospect that its future stock will be drawn from those who can afford to pay for a medical education rather than those best suited by their ability to benefit from it, says the association, in a letter to the Department of Education and Science.

Surveys reveal considerable disillusionment among young doctors about careers in medicine, says the BMA. Of those qualifying in 1981, 46 per cent expressed regret at having entered medicine, compared to 28 per cent in 1976. If young doctors are also faced with large outstanding loans from their undergraduate days, this disillusionment will only get worse. The association estimates that by 2006 a junior doctor could have a total loan to repay of up to 35 per cent of his or her first year's income.

The BMA urges the government to reconsider its plans for a loans scheme and instead to restore the recent loss in real value of the grant. Christine McGourty

Arianespace order

Paris & Tokyo

THE night of 27 January was a busy one on launch pads around the world. At 01.21 GMT, Arianespace, the consortium operating European space launches, put an Intelsat V communications satellite into geostationary orbit. Just a few hours earlier, on the other side of the globe, the Japanese National Space Development Agency successfully launched the TR-1(2) prototype for its H-II rocket.

The European launch from Kourou in French Guiana confirmed Arianespace's lead in the commercial satellite launch market. With an order book for 36 launches, nine of them scheduled for this year, Arianespace hopes to repeat last year's turnover of $520 million.

In February, Arianespace will sign an order for 50 Ariane-4 launchers, worth more than $4,500 million, and intended to be the company's workhorses until 1999. Japan hopes one day to take a slice of that market. But it will be at least 1992 before the H-II rocket is complete, and commercial launches are not expected to begin until the late 1990s. By then, H-II's 4-tonne payload may look small compared with that of planned new Ariane launchers.

Peter Coles & Alun Anderson

New chairman

Munich

THE West German Wissenschaftsrat (science council) chose Dieter Simon as its new chairman at a meeting in West Berlin on 27 January. Simon, a law scholar and director of the Max Planck Institute for European legal history in Frankfurt, replaces physician Kurt Kochsiek of Würzburg.

Simon led a strike of the scientific review commission of the Wissenschaftsrat in December of last year (see *Nature* 336, 506; 8 December 1988) to protest at the demotion of the council's general-secretary to the lowly status of a public servant. Pressure from the political heads of the *Länder* in late December pesuaded the federal government to restore the general-secretary position, currently unoccupied, to its original higher status.

In his final statement, Kochsiek pleaded with the *Länder* to increase their education budgets by twice as much as they had planned in order to alleviate overcrowding and a decline of quality at West German universities. S. D.

New NSF positions

Washington

RICHARD Nicholson, at present assistant director for mathematical and physical sciences at the National Science Foundation, was last week named as the new executive officer of the American Association for the Advancement of Science. He replaces Alvin Trivelpiece who left the association at the end of last year to become director of the Oak Ridge National Laboratory. Nicholson is expected to join the association by mid-April.

The foundation also announced last week that Mary Clutter would take over as assistant director for biological, behavioural and social sciences. She replaces David Kingsbury, who resigned last October amid allegations of conflict of interest over his dealings with a biotechnology company. J. P.

Accelerator all set

Washington

BACKERS of the Superconducting Super Collider, the proposed $4,400-million proton accelerator, now have everything they need except congressional approval for construction funds. Two weeks ago, Waxahachie, Texas, was confirmed by outgoing Secretary of Energy John Herrington as the site of the Superconducting Super Collider after a review of the full environmental impact statement, and last week the Department of Energy signed a nine-year contract with the Universities Research Association, a consortium of 66 universities, to manage and operate the facility. The association runs the Fermi National Accelerator Laboratory near Chicago, and was the only bidder. D. L.

Rifkin tries to block human gene transfer experiment

Bethesda

THE first experiment to insert foreign genes into humans, which received approval to proceed only two weeks ago, may be blocked by Jeremy Rifkin, an active opponent of genetic engineering.

On 30 January, Rifkin's Foundation on Economic Trends filed a suit in a US federal district court to stop W. French Anderson of the National Heart Lung and Blood Institute and R. Michael Blaese and Steven A. Rosenberg of the National Cancer Institute from carrying out the experiment. The plan is that tumour-infiltrating lymphocyte (TIL) cells marked with a gene for antibiotic resistance will be injected into ten cancer patients from whom the cells were isolated.

Rifkin has filed his suit because he says the approval process of the National Institutes of Health (NIH) did not fully review the experiment or allow for public debate in the final stage. But NIH officials point out that there has been ample opportunity for open discussion and the experimental protocol has undergone a complex and lengthy review process.

The road to approval for the gene transfer experiment has not been smooth. Anderson and his colleagues first proposed their experiment last June, and it was referred first to various institutional review committees and then to the NIH Recombinant DNA Advisory Committee (RAC) for approval. A RAC subcommittee on human gene therapy first concluded that more data were needed, but at the end of September, Anderson told the subcommittee that he did not have the data it was seeking, whereupon the committee deferred approval of the protocol.

But on 3 October, Anderson presented much of the same data to a full meeting of the RAC, which approved his experiment. NIH director James Wyngaarden ordered that the subcommittee be given a second chance to review the proposal in the light of the new data, and the application was afterwards resubmitted to the full RAC, which approved it by mail ballot.

Rifkin objects to the mail ballot. Andrew Kimbrell, policy director and attorney for Rifkin's foundation, says that after the 3 October meeting, significant changes were made to the experimental protocol which under federal law should have been debated in an open RAC meeting, adding that the RAC review process in this case has been "confused, backwards and illegal". Speaking at this week's RAC meeting, Wyngaarden countered that there were no substantive changes to the protocol approved at October's open RAC meeting, so a further public meeting was unnecessary. The gene therapy committee's final deliberations, held on 9 December, were public.

But Wyngaarden does agree that the Anderson case has pointed to a problem with RAC procedures. He announced last Monday that he would seek an amendment to the RAC charter requiring that protocols referred to a RAC subcommittee to be approved by that subcommittee before being put to the full RAC.

Anderson says he thinks Rifkin's lawsuit is "a good thing" because it will bring the issue out in the open for public discussion. But Rosenberg points out that an American dies from cancer every minute, and "any delay for any reason would be very unfortunate."

Rifkin also used the forum of the RA meeting to propose an amendment to NI guidelines that would establish a Huma Eugenics Advisory Committee to provid advice on the "ethical, philosophica social, economic and eugenic implicatio and impacts of human genetic therapy".

But RAC chairman Gerard McGarrit pointed out that the RAC does not hav the administrative authority to create suc a committee. Such amendments can onl be made by the Secretarty of the Depart ment of Health and Human Services wh approves RAC's charter. Nevertheless the RAC spent nearly two hours debatin the merits of the proposal, and althougl there was general support for the idea most felt existing review bodies coul cope with the issues that a eugenics com mittee would address. **David Swinbank**

Errors in US census rouse political protests

San Francisco

TIME is running out to resolve the political and legal challenges to the way the 1990 US census will be conducted. Yet practical issues such as how to count the minority population of large urban areas and whether to count illegal aliens will have a profound effect on the social fabric of the United States in the next decade.

The decennial census is used not only for allocation of congressional representatives among the 50 states, but also for the distribution of federal funds to states and cities for services such as hospitals, schools, highways and housing. But the census usually misses 10 per cent or more of the minority population in some urban areas, and the cities most hurt by the undercount have accused the Bureau of the Census of ignoring a proven statistical means of correcting the numbers.

Census bureau decisions are subject to strong political pressures, as a small change in population can mean the gain or loss of a congressional seat. Since 1970, the census has been taken largely by mailed questionnaires; enumerators are sent in person only to households that do not respond. The method runs into difficulties in poor urban neighbourhoods.

After the 1980 census, the census bureau faced 37 lawsuits by areas contending that their minority population had been undercounted, all of which were unsuccessful. Nevertheless, the bureau developed a method called the Post Enumeration Survey (PES), using an in-depth survey of 300,000 households drawn from representative city blocks, to adjust its first counts. A test of PES in Los Angeles demonstrated a 9 per cent undercount in black neighbourhoods.

Barbara Bailar, chief of the team that devised the method, acknowledges that PES will still miss people who actively avoid being counted, but says it will nevertheless bring the numbers closer to the truth. Despite endorsements from three scientific committees, the census bureau has decided not to use PES to adjust the 1990 census. The bureau claims its existing methods are sufficiently accurate, and that PES would be too expensive.

Bailar resigned in protest at the decision, complaining that the census uses other, less-sound adjustment methods costing more than the $31 million required for PES. Some claim that the decision is politically motivated by Republican fears of losing congressional seats, as the undercounted populations typically vote Democratic.

Meanwhile, a coalition of cities and minority advocacy groups has launched a lawsuit to compel the bureau to shift to PES. A bill with the same objective introduced in Congress was killed last September by the addition of an amendment requiring the exclusion of illegal aliens from the census. The census does not at present aim to determine citizenship, and the census bureau is being sued by a coalition of congressmen who oppose counting illegal aliens for apportionment of congressional seats.

The census bureau defends the inclusion of illegal aliens on the grounds that the constitution requires counting all residents. In any case, says Jeffrey Passel of the census bureau, excluding illegal immigrants would be difficult because it would require the determination of citizenship, requiring all non-citizens to be matched against Immigration and Naturalization Service records, known to be in disarray. **Marcia Barinaga**

Hungary breaks science links with Romania over Transylvania

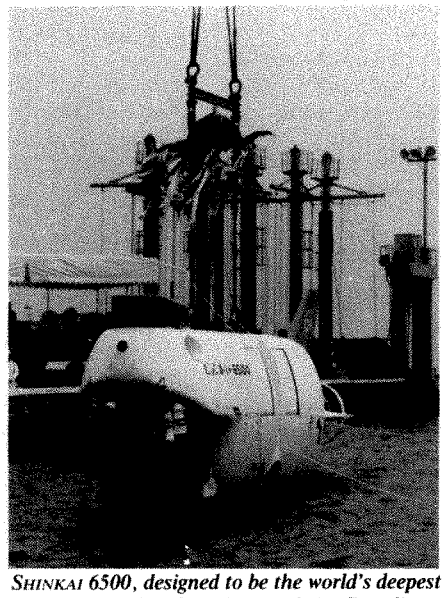
London

A LETTER from Romanian scientists appealing to Hungarian colleagues not to break off scientific relations was recently read at a closed session of the Hungarian Academy of Sciences. This emerged at a meeting of the Hungarian government's cultural and foreign affairs committee last month. But the letter came too late. Talks between the two governments on cultural, educational and scientific cooperation seem to have broken down over the issue of Transylvania.

The dispute between the two countries dates back to the settlements after the First World War, when the Treaty of Trianon awarded Transylvania to Romania. But the Hungarian presence in Transylvania goes back more than a thousand years — Magyars were there before occupying what is now Hungary in 895 AD. In the sixteenth and seventeeth centuries, Transylvania was for a time the heartland of Hungarian resistance to the Ottoman Empire.

The Romanian policy of de-Magyarization of Transylvania began in 1918. Since the Second World War, despite the establishment of socialist regimes in both Hungary and Romania, Romanian policies in Transylvania have continued, but Hungarians have been reluctant to criticize the Romanians in public.

The Hungarian "Bolyai" University at Cluj-Napoca (formerly Kolozsvar) was closed down (the Rector committed suicide) and, during the 1970s and 1980s, reports of discrimination against Transylvanian Hungarians in education and professional employment became increasingly frequent and alarming.



Since 1987, the Romanian government has been "consolidating" agricultural settlements, which means the destruction of the villages of Transylvania and the resettlement of the inhabitants in high-rise "agro-industrial settlements". Thousands of Transylvanian Hungarians have fled across the border, swamping the Hungarian social services. Private initiatives and action by the churches have, at best, offered only temporary relief. There are 2.3 million Hungarians in Transylvania but only 10.5 million in Hungary itself.

Diplomacy by the Hungarian government has come to naught. The Romanians inisist that the destruction of the villages is "rational" and "scientific" and point out that they have sent in "conservation" officers to photograph anything of interest before it is bulldozed.

Increasingly, the Hungarians are calling for an "international" solution. In an unprecedented move for a Socialist country, Hungary has invited a delegation from the UN High Commission for Refugees, which is due in Hungary next week. There have also been appeals by Hungarian "democratic" and "informal" movements in Hungary for the application of sanctions to Romania.

In Britain, there have been several calls for Madame Elena Ceaucescu to be stripped of the academic honours conferred on her by such bodies as the Royal Society of Chemistry. Although Ceaucescu is not, formally, responsible for the destruction of the villages, she is widely believed to be the real power behind the president. Although she is acclaimed as Romania's greatest scientist, others have questioned the quality and originality of her publications. But the Royal Society of Chemistry says that Ceaucescu was elected as a Fellow to the Royal Institute of Chemistry in the regular manner on the basis of her chemical career and publications, and that the charter of the Royal Society of Chemistry provides for the expulsion or suspension of a fellow only in the case of a criminal conviction, failure to observe the Society's bylaws or "conduct detrimental to the welfare of the society". **Vera Rich**

Sub's first outing

SHINKAI 6500, designed to be the world's deepest diving research submarine, took its first dip at Mitsubishi Heavy Industries shipyard in Kobe, Japan, last week. Its titanium alloy hull and pair of external manipulators will allow it to collect samples from the ocean bottom at depths of 6,500 metres, 500 metres deeper than vessels operated by other countries. After sea trials, the submarine will be delivered to the Japan Marine Science and Technology Center (JAMSTEC) in November. JAMSTEC will use the submarine to investigate the causes of undersea earthquakes, to assess deep ocean-bottom mineral resources and to study deep-sea life. Alun Anderson

New complaints about US waste in the Antarctic

Sydney

GREENPEACE in Australia has joined environmental groups in the United States in accusing the US government of leaving behind an environmental mess at research facilities in Antarctica. A scientific committee on Antarctic research, made up of scientists from Antarctic Treaty signatory countries, will meet next October to recommend new waste disposal practices for the Antarctic.

The Australian group is focusing on two bases in the Antarctic — Wilkes, a former US and Australian base, and McMurdo, the present US base. Wilkes was established by the United States in 1957 as a temporary base before McMurdo was completed. In 1964, the Australians took over the abandoned base, where they remained until 1969 when they moved to their present base, Casey.

According to a spokesperson for Greenpeace Australia, Lyn Goldsworthy, when Wilkes was abandoned "a lot of rubbish was just left behind". This included 200–300 petrol drums, many still full, old food sacks and derelict buildings.

In 1985, the US government gave Australia permission to clean up Wilkes. Rex Moncur, acting director of the Australian Antarctic Division, says that although the Wilkes buildings are technically US property, Australia accepts responsibility for cleaning up the site, and plans to start work at the end of this year.

Greenpeace in Australia claims that McMurdo is still generating a dangerous amount of waste. Goldsworthy says McMurdo's sewage system discharges directly into the sea, and that some parts of the ocean floor off McMurdo are heavily contaminated with polychlorinated biphenyls. She says Greenpeace has evidence that waste items such as batteries have been found at dump sites, contravening the code of conduct of waste disposal of the Antarctic Treaty.

Jack Talmadge, section head for polar coordination and information at the United States National Science Foundation, says the US government has always taken the waste problem seriously, and the recent reports have merely focused outside attention on the issue. Talmadge says the foundation's budget request for 1990 includes initial money for a four-year, $30-million safety and environmental health initiative that will clean up existing problems and establish new procedures and equipment to forestall new ones. "We're taking the high road in getting the job done", he says. **Tania Ewing**

Science literacy found wanting in United States and Britain

San Francisco

MORE than 90 per cent of adults in the United States and Britain are scientific illiterates, according to survey results released last month at the annual meeting of the American Association for the Advancement of Science in San Francisco. Its authors claim that it is the first such survey to be carried out in both countries, allowing comparisons to be made easily.

The dismal state of scientific literacy in the United States has recently prompted renewed attention to science education. The new surveys, developed in the United States, were designed to determine whether people have a minimal level of scientific literacy. To test for a basic understanding of scientific methods, respondents were asked "what does it mean to study something scientifically?".

Answers judged correct included testing of hypothesis and building of theory, the use of experiments, or systematic comparative study. As a check on this understanding, those who answered the question correctly were then asked to say whether astrology is "very scientific", "sort of scientific" or "not scientific at all". Only those who said astrology is not scientific at all were classified as having a general understanding of how science is conducted.

Simple questions such as "does the Earth go round the Sun, or does the Sun go round the Earth?" were used to judge understanding of scientific concepts. To assess understanding of the impact of science on society, respondents were asked questions such as "is it true radioactive milk can be made safe by boiling it?". (After the Chernobyl accident, a household in Cumbria in northern England was found to be boiling milk as a protective measure.)

Only six per cent of US adults and seven per cent of British were found to have at least minimal understanding of the process, concepts and impact of science. The US results were comparable to those of earlier surveys in 1979 and 1985.

Jon Miller, director of the Northern Illinois University Public Opinion Laboratory, who carried out the US surveys, blames the widespread scientific illiteracy on inadequate education, particularly at the high school level.

But some question the validity of the surveys, claiming that they tend to overestimate illiteracy because of misunderstandings of the questions. As an example, some members of the general public confuse astrology with astronomy.

There are interesting differences between Britain and the United States in questions relating to medicine. In a self-assessment, more US than British respondents (80 per cent against 50 per cent) said they are "very interested" in new medical discoveries. Similarly, about 70 per cent of US adults consider themselves "moderately" to "well informed" about such discoveries. But the high self-assessment does not translate into knowledge.

On several medical questions, US adults actually fared slightly worse than their UK counterparts. For example, 75 per cent of US respondents falsely believe that antibiotics are effective against viral infection, as against about 70 per cent of British. And although US adults were better at identifying risk factors for heart disease with more than 90 per cent correctly pinpointing smoking, lack of exercise, stress and eating too much animal fat, higher percentages of US adults (50–65 per cent) falsely believe that food additives and lack of vitamins, fresh fruit and fibre contribute to heart disease.

Miller says the dismal results in both countries are a "threat to democracy". He notes that science and technology are playing an increasing role in society but that the vast majority of people are not sufficiently literate in science to make informed decisions about major issues related to science.

Miller's solution is a radical improvement of the scope and quality of pre-university science education.

David Swinbanks

RVS move opposed

London

THE plan of the UK Natural Environment Research Council (NERC) to create a centre of excellence in oceanography at the University of Southampton will have to be redrawn to exclude the transfer of the Research Vessel Services (RVS) from Barry in South Wales, if staff at the base get their way.

The RVS provides the shipborne instrumentation, data acquisition and computer facilities necessary for marine research programmes of NERC and universities throughout the country. More than 60 of the 70 members of the RVS staff based at Barry are opposed to the move, according to one member of a committee formed to campaign against the relocation, who asked not to be named as staff have been asked not to speak to the press.

The committee has written to council members of NERC and to the secretaries of state for science and for Wales protesting against the plan, arguing that groups throughout the country rely on the services of RVS and that relocation at Southampton cannot be justified on the grounds of improved accessibility to the unit's services. They say that the move will cost £10 million, a sum that could be better spent on modernizing the equipment of the RVS. Creation of the centre at Southampton will cost £35 million over five years. The plan will go ahead if the government agrees to provide the money; an announcement is expected in the next few weeks.

Christine McGourty

Protection of endangered species threatened

Washington

PROGRAMMES to safeguard endangered species in the United States are themselves threatened by a lack of funds, says a report released at the end of January by the Government Accounting Office (GAO).

The Endangered Species Act of 1973 requires that the responsible agencies, either the Fish and Wildlife Service (FWS) of the Department of the Interior or the National Marine Fisheries Service (NMFS) of the Department of Commerce, should develop and put into action recovery programmes for species classified under the act. Although the GAO makes no attempt to assess the biological efficacy of these programmes, it finds that for 40 per cent of the classified species no recovery plan has been formulated, and that in the 18 cases it reviewed in detail only half of the steps in the plans have been initiated. The problem is compounded by failure of the FWS and NMFS to follow systematically the progress of its recovery plans.

Of the 482 species classified as threatened or endangered, fewer than one-sixth, according to the report, are increasing in numbers, and one-third are continuing to decline. The report also identifies a failure within FWS, which is responsible for 464 of the 482 classified species, to assign priorities to various species according to its own guidelines. This is partly due to pressure from Congress, which in 1987 forced FWS to spend 11 per cent of its recovery funds on only eight species, and partly due to a perceived need by FWS to provide a strong effort in some highly visible cases, such as the American bald eagle.

The GAO lays most of the blame on a simple lack of money, as well as organizational deficiencies in FWS and NMFS. But it also recognizes that recovery of some species may be unlikely, regardless of human efforts: the fragile desert habitat of the New Mexico ridgenose rattlesnake and the Texas beaches on which Kemp's Ridley sea turtle breeds are steadily shrinking, despite conservation efforts.

David Lindley

"Erosion of UK research on agriculture and food must end"

London

CUTS in government support for near-market research were severely criticised last week by the House of Lords Select Committee on Science and Technology. In a report on agriculture and food research in Britain, it said the government should reassess the list of projects defined as near-market so as not to include research which is in the public good, such as animal health and welfare, food safety and quality standards and protection of the environment.

The committee also recommends that the proposed timescale of three years for the transfer to industry of support for near-market research should be extended to five. Savings made in this exercise should be used to support basic and strategic research.

Although some of the rationalization in the Agricultural and Food Research Council (AFRC) has been to good effect, the cuts and the uncertainty about future

levels of support have caused instability and severe problems in the research community, says the committee. Industry should make a major contribution to the cost of research aimed at increasing industrial profitability and competitiveness, but the committee warns that if a sound research base is not maintained through public support, then commissions are likely to go overseas.

The research base in agriculture and food should not be reduced further, says the committee. A period of stability would lead to a reversal of the damaging trend towards more short-term appointments. Such appointments are appropriate when projects are of fixed length, but should not be used simply because future finances are uncertain. In the AFRC, the number of short-term appointments is already too high, it says.

The Ministry of Agriculture, Fisheries and Food comes under searing criticism from the committee. Scientific knowledge has had little impact on the ministry's policy, it says; because of the inadequate number of staff and an inappropriate structure, interaction with researchers is inadequate, as is the provision of proper guidance and advice.

The committee also criticizes the ministry's performance as a customer for research. Although it supports the principle that applied research should be supported on a customer contractor basis, its performance has been poor. Because of this, the committee recommends that funds transferred in 1975–76 to the ministry from the then Agriculture Research Council should be returned to the AFRC, or given to the proposed Natural Resources Research Council (NRRC). (In its interim report on agriculture and food, the committee recommended that a new council, the NRRC, be formed from a merger of the AFRC with the Natural Environmental Research Council.) The money — about £27 million — would be more productive as part of the AFRC or NRRC budget, says the committee.

The Biotechnology Directorate of the Science and Engineering Research Council is praised by the committee, but it says that the other research councils should be involved in the directorate's activities. There should be more joint initiatives, for which proposals should come from a new advisory group. It says that more research is needed on plant biochemistry and physiology, and it recommends more research on nutrition and forestry.

Christine McGourty

US plan for proton accelerator to produce tritium for warheads

Washington

AN old idea for producing tritium for nuclear warheads is gaining new favour in the United States. A report compiled by scientists and engineers at Los Alamos National Laboratory, Brookhaven National Laboratory and Westinghouse Hanford Company, which is soon to be submitted to the Department of Energy (DoE), advocates construction of a huge linear proton accelerator for the production of tritium; it may be powered by excess electricity from hydroelectric sources.

The closure last spring of the ageing Savannah River reactors, the sole US source of tritium for nuclear bombs, forced DoE to consider alternative production methods. Last summer, the department announced plans for two new production reactors, a heavy-water reactor at Savannah River and a modular high-temperature gas reactor at the Idaho National Engineering Laboratory (see *Nature* **334**, 558; 18 August 1988). The DoE budget request for 1990, compiled by the former Reagan administration, includes some money to start building the reactors. But a draft of the Los Alamos–Brookhaven–Westinghouse report claims that accelerator production of tritium would be cheaper and safer.

The principle of accelerator production is simple. A beam of high-energy protons is fired at a lead target to produce high-energy neutrons which in turn hit a lithium target which emits helium and tritium. The same approach is used in production reactors where the source of the neutrons is nuclear fission.

Wolfgan Panofsky, emeritus director of the Stanford Linear Accelerator Center, says the proposed accelerator is "well within the capabilities of present technology". In fact, he says, a prototype accelerator with a proton beam current comparable to that proposed (250 milliamps) was built at Livermore for the production of plutonium and tritium in 1949. Panofsky also agrees with the report's conclusion that the accelerator system will produce less radioactive waste than a production reactor.

But a key problem will be providing the gigawatt of electricity the accelerator will need. Building a new nuclear reactor to supply the accelerator would defeat the original purpose. But Pierre Grand of Brookhaven, who helped to compile the report, says that Bonneville Power Administration in Washington state, where advocates hope to site the accelerator, has tentatively said it can provide about 900 MW from excess hydroelectric generating capacity.

Another open question is cost. The report estimates that the 1.6-GeV facility will cost about $2,300 million with annual running expenses of $250 million — considerably cheaper than the estimated $6,800 million required for new production reactors. But Grand emphasizes that these figures are "very preliminary".

David Swinbanks

Genetics of schizophrenia

SIR—As is his wont, Steven Rose (*Nature* **336,** 512; 1988) belittles the efforts of molecular biologists to understand human problems. Rose's objection that "Sherrington *et al.* have not shown that [the locus on chromosome 5 to which their RFLP markers are linked] is sufficient [for a person to develop schizophrenia] — a prerequisite for useful genetic counselling — is misleading on two points. First, Sherrington *et al.* (*Nature* **336,** 164–167; 1988) did not claim that they had found a locus which inevitably leads to schizophrenia. They specifically quote a penetrance of 85 per cent even given a broad definition of schizophrenia-related diseases, stating that there are influences at work other than the genetic ones they have identified. Second, the locus is useful for genetic counselling whether or not it determines schizophrenia in the way that Rose would require of it. Genetic counselling has for many years relied on statistical arguments, often stemming only from mendelian genetics, with no linked markers at all. Many couples have felt that to be told that their children have a 25 per cent change of suffering from (say) cystic fibrosis is better than knowing nothing. Even with the advent of more statistically certain markers, such as the G8 probe which is linked to the locus causing Huntington's chorea, it is clearly recognized that possession of the locus is quite compatible with survival to 70 years of age with intact mental faculties. As always, genetic counselling is not only genetics — it is also counselling on the interpretation of those genetics.

This is exactly the reverse of the reductionism that Rose so vividly describes, but which is not actually present in your original articles: it is placing human interpretation on molecular results. That Rose invokes this argument only to knock it down as counter to a human science is at least consistent with itself, if not with the facts. That he then uses it to argue against attempts to develop more carefully targeted drugs to treat incapacitating mental disease is obtuse. Of course this course has not been successful in the past. It has not been available in the past. On this argument we would still be treating schizophrenia with the ducking chair and the stake.

Reprints justified

SIR—I agree with Ivor Smith (*Nature* **336,** 708; 1988) that sending reprints is costly and time-consuming. In places such as Italy however, photocopiers abound, but university libraries do not subscribe to major journals, or journals are distributed only after months of delay. In such cases, it is vital for investigators to receive reprints (or even cheap photocopies) of papers within a few weeks of their listing in *Current Contents* or similar indexes.

MARCO RUGGIERO

Istituto di Patologia Generale,
University of Firenze,
Italy

SIR—I request reprints because it saves time. I subscribe to *Current Contents* and, on average, request three or four reprints per week, which takes about half an hour. If I were to go to the library, find the journals and copy the articles, it would probably take at least half a day. And often the journals that I need are not in the library because of budget cuts.

I feel that an investigator has the obligation not only to do research but also to disseminate it. Most administrators would probably be glad to provide the cost of photocopying and postage to have research at their institution known and cited.

M.B. KIRKHAM

Swiss academic strife

SIR—The picture drawn by John Maddox (*Nature* **336,** 333; 1988) of Swiss academic life is in my opinion a bit too rosy. I agree that there are a few positive aspects: faculty salaries, particularly those of senior professors, are high; retirement benefits are generous; SNFS research grants are easily obtainable. On the other hand, I do not share the view of ample opportunity for research. Minimum teaching loads for faculty at the University of Zurich, for example, are eight hours a week; an excessive amount of time is spent at *ad hoc* committee, departmental, faculty and senate meetings, occasionally lasting past midnight; and a similar amount of time is spent in exchanges with hordes of administrators at all kinds of levels of the education ministry of the canton.

As noted by Steven Dickman on the same page, student/faculty ratios are extremely biased in some fields. Even more crucial, it seems to me, is that as a by-product of a lax or non-existent admission policy, the range in quality of students is also extreme. This, in combination with the large number of students, has led to a decline in the quality of research and teaching, approaching mediocrity at best in some departments.

The bending of rules by cantonal officials to allow foreign academics to buy housing without having lived in Switzerland for five years is certainly a nice gesture. By contrast, once arrived in the land of Alps, foreign academics are often treated as second-class fellows by their Swiss colleagues. I believe there may be an analogy here to the treatment of women as second-class citizens in Swiss society. In 1984, Frau Elisabeth Kopp was elected by her parliamentary colleagues into the executive branch of the federal government, a first in Swiss history. How about the faculty of one or the other Swiss university electing one of their foreign colleagues to a deanship or even a chancellorship? Recently, Kopp was forced to resign from her cabinet post. I hope that is where the analogy would break down.

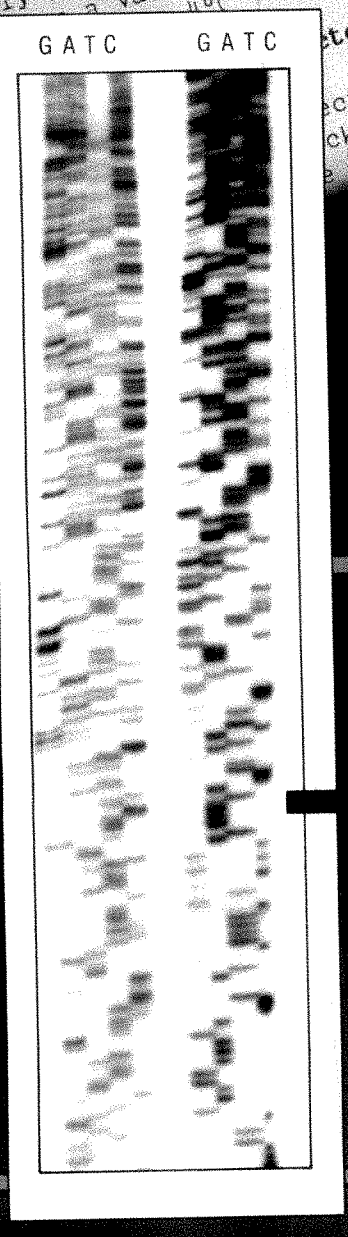
Obfuscation



SIR—The recent letter by C. A. Smith *et al.* (*Nature* **337,** 181–84; 1989) seems to be an example of the apoptotic misuse of the Greek language. As before with other Greek words, I was unable to establish an unambiguous meaning of apoptosis. αποπτωσω is translated in the standard Greek–German dictionary as *verirren* (to go astray), so apoptotic might then be aberrant, and apoptosis could be translated by aberration. Using these meanings in the article, however, I was led astray: apoptosis as a process related to T lymphocytes, apoptotic as characteristic of these cells remained meaningless. The authors, however, seemed to like the word. But for a broad understanding of the article it is misleading. I am afraid that such use of cryptic Greek language by British scientists is a way of establishing barriers between them and others — deliberately, I wonder?

SDS-PAGE, 2-D electrophoresis, blotting, and electro-elution. All in the same cell.

Every mini cell is fast; only one is versatile.

Electrophoretic blotting of two mini-gels can be completed in one hour. Minimum buffer requirements and a self contained cooling system are two advantages of this rapid miniature blotting cell.

SDS-PAGE electrophoresis is completed in only 40 minutes. The Mini-PROTEAN™ II cell's leakproof casting system and snap-on clamp assemblies simplify set-up procedures for running SDS-PAGE gels. Its capacity for up to 30 samples makes it ideal for rapid screening applications.

IEF tube gels for 2-D are finished in 90 minutes. High resolution 2-D analysis, including silver staining, is completed in half a day.

Preparative recovery of nucleic acids and proteins is easily accomplished with the Model 422 Electro-Eluter. Patented Membrane Caps with self contained dialysis membranes simplify assembly and insure leakproof sample collection with ≥ 80% sample recovery. Available as a stand-alone unit or as a module for the Mini-PROTEAN II cell.

All you need is one cell — the Mini-PROTEAN II SDS-PAGE electrophoresis cell. Three different modules are available to transform this popular cell into a mini-tube cell, a Mini Trans-Blot™ cell, or an electro-eluter.

Just remove one module and drop in another. It's that easy. Each module is also available with its own buffer tank and lid, which will make it a stand-alone instrument.

No other mini electrophoresis system offers such convenience and versatility. More than that, you'll economize on reagents, speed up your runs, and save substantially by not having to buy extra equipment as your electrophoresis applications expand.

For details on this innovative approach to mini electrophoresis, contact us and ask for Bulletin 1273.

Custom Peptide Synthesis

... is not as Simple as that!

Therefore rely on our specialists' experience when it comes to high quality products. Our qualified team of peptide chemists is ready to provide you with custom synthesized peptides, off-the-shelf bioactive peptides, resins for solid-phase synthesis, and RP-Silica for MPLC peptide purification.

Call us today to discuss your individual requirements.

Reader Service No.59

BTN Biotec Nordhorn GmbH
Enschedestraße 14 D-4460 Nordhorn Tel.: 05921-17941 Telex: 5921814 = STVWNOH Telefax: 05921-17950

Scientists serving scientists in Switzerland, UK, West Germany and worldwide.

Novabiochem manufactures a wide range of speciality biochemicals:

- Biologically active peptides
- Amino acid derivatives, reagents and resins for peptide synthesis
- PAF and PAF antagonists
- Biologically active lipids and phospholipids
- Enzyme substrates and inhibitors
- Anti-peptide antibodies

novabiochem

Switzerland

United Kingdom

Germany

QUALITY

We manufacture to the highest standards of purity, under GMP (Good Manufacturing Practice) conditions. All products are supplied with comprehensive batch-specific analytical data sheets.

SERVICE

Large stocks are held by all three Novabiochem companies, as well as by many of Novabiochem's worldwide network of distributors, allowing rapid delivery at all times. Technical support is available from Novabiochem's scientists and technical library.

BULK QUANTITIES

Of most items in our range are available from stock.

PHARMACEUTICAL GRADE PEPTIDES

Are our speciality. We produce peptides under FDA-approved GMP conditions in quantities from tens of grams to kilograms. Many are available from stock, but we can also undertake custom synthesis of peptides, biologicals, biochemicals and other pharmaceutical intermediates.

More ways with neural networks

Ridding neural networks of some of their limitations seems to have suggested ways not just of accounting for the way that attentiveness can improve perception, but for human frailty as well.

PHYSICISTS, as eager as ever to believe that even biology is only applied physics, are naturally attracted to the notion that neural networks are a useful model for thinking processes capable of pattern recognition. One reason is that the formal description of networks is nicely mathematical. Another is that networks have already been used to solve other problems. An obvious, indeed an almost exact, analogy is that of the structures called spin-glasses, systems in which randomly distributed spins, magnetic or otherwise, interact with each other with a strength dependent on their random separations.

What could be more like the model of, say, the cortex, in which ON/OFF elements stand for neurons and in which the synaptic interconnections are described by coefficients whose magnitude determines the degree to which one neuron influences any other? Work on the spin-glasses was the first clearly to show that there is no unique equilibrium state of such a system but, rather, a large set of configurations, each of which represents a local minimum of the physical free energy.

In spin-glasses, these configurations are those in which the system may be trapped if the temperature is not great enough to allow random processes to discover and then to occupy another energy minimum with lower energy (which is the process of annealing). In neural networks, the same local minima correspond to the built-in patterns of the stimuli the network is capable of recognizing. Put crudely, a randomly chosen stimulus will first excite the network into a new state, which will then relax towards that built-in configuration to the stimulus most closely corresponds. In practice, this means that neural networks can recognize even very distorted versions of their built-in patterns.

But how well do the neural networks represent the real world of cognitive pattern recognition? While nobody expects utter precision from such inherently simple models, there are several respects in which they fail to correspond with everyday experience. All of us, for example, know that we can unconsciously, or even consciously, modulate the ease with which we recognize particular patterns by concentrating our attention on them: by what means do we adjust the coefficients representing synaptic strength in the manner this everyday observation implies? And what is to be said of the all-too-familiar situation that the cortex, when presented with some arbitrary stimulus, can only tell us that it cannot make sense of what it has perceived — that no one built-in pattern seems more appropriate than any other?

Two researchers seem now to have been able to adapt the standard neural network model to these needs, suggesting how it may be possible for a working neural network to adjust its own noise level and thus the ease with which particular patterns may be perceived. As a by-product, they suggest how the same modification may allow neural networks quickly to recognize which stimuli are novel.

Maciej Lewenstein and Andrzej Nowak, respectively a theoretical physicist from the Polish Academy of Sciences institute and a psychologist from the University of Warsaw, take the acknowledged defects of existing neural networks as the starting-point for their new construction (*Phys. Rev. Lett.* **62**, 225; 1989). Much of their argument is stimulated by the Monte Carlo computational techniques applied, for example, to the calculation of the stationary states of spin-glasses: by flipping randomly chosen spins in an initial configuration, it is possible to move systematically towards a nearby local minimum of the free energy. But the argument is, mercifully, not just another exercise in computational simulation.

First, Lewenstein and Nowak seek to distinguish between two kinds of built-in patterns or memories, some of which are more 'strongly' memorized than others. The operational difference is that between deep and shallow wells in a free energy surface, but the authors say it is the kind of categorization that might be found in hierarchically organized memories. How to organize such an arrangement?

The underlying assumption in the analogy between neural network models and the real cortex is that both structures must 'learn' which patterns to 'memorize', which requires that neural networks should discover what pattern of coupling strengths between different pairs of elements will embody a learned pattern in a stable fashion — and that neurons in the cortex should similarly grow appropriate synaptic connections.

What the authors find is that their networks will acquire a number of poorly 'remembered' patterns if equal weights are assigned to them in constructing the coupling constants between pairs of elements and if the well-remembered patterns are blessed with larger weights. Among other things, they find that the capacity of the network to recognize the poorly remembered states in an input stimulus is not impaired. But the unequal treatment does have the effect of reducing the number of the distinctive patterns the network may embody. In reality, there is no reason why the result (hierarchy) should not be advantageous in a real cortex.

The more striking innovation is that used for allowing the model neural network systematically to adjust its own precision, which is done by building into the equations rules that describe the way in which the noise level of the system is locally determined by the the lability of the network during its dynamic evolution.

The noise in the system must be likened to thermal noise, and determines the likelihood that it will spontaneously migrate from one local minimum to another that is more stable. But under the influence of an external pattern, all the spins will be shaken up (neurons will be switched off and on), whereafter the system will evolve to the remembered pattern most nearly determined by the stimulus.

The rules allowing the analogues of attentiveness to be built into recognition by a neural network are recurrence relations relating the noise at one point in the pattern-seeking process to that at an earlier stage by means of quantities representing the numbers of elements in the network changing their state in the interval.

Those working in the field will no doubt be eager to get their hands on the details. For the rest of us, the qualitative implications may suffice. Thus a neural network in the process of homing onto a remembered pattern will, anthropomorphically speaking, do so with increasing confidence. But a network presented with a stimulus that cannot easily be recognized for what it is will change the states of a great many elements in hunting for a solution, the noise will as a result increase and the network may, in effect, be saying 'don't know'. There is also the possibility that the state of a network faced with a badly chosen stimulus will as a consequence be impelled into a noisy state and then driven by random procesess towards the wrong attracting image state. In short, this adaptation of the standard neural network seems both to account for known psychological effects and for a good deal of human frailty — uncertainty and downright misjudgement.

Animal behaviour

The sight of deep wet heat

Michael F. Land

DAYLIGHT disappears at a depth of about 800 m in the ocean. There are simply too few photons left for eyes to capture them in numbers large enough to provide statistically usable signals[1,2]. Below this depth most of the sparse fauna is eyeless. In the black depths of the Mid-Atlantic Ridge, 3.6 km deep, there are volcanic vents emitting very hot (350 °C) sulphurous water. Inhospitable as these sound, they are far from sterile. In particular they are inhabited by swarms of shrimp feeding on the sulphur-metabolizing microorganisms (see figure) that find the sulphide chimneys congenial. The strange thing about these shrimp is that they possess hugely developed structures that have much in common with eyes, as Van Dover *et al.* report on page 458 of this issue[3], even though the usual spherical eyes of ordinary shrimp have disappeared. What might be the function of these strange organs?

R. exoculata *swarming over the surface of sulphide chimneys at Mid-Atlantic Ridge hydrothermal vents. The bright patch on their backs corresponds to a novel visual organ described by Van Dover* et al. *on pages* 458–460 *of this issue. (Photograph by Andrew Campbell.)*

There is a considerable amount of bioluminescent activity in the deep sea, including near sulphide chimneys, so it is possible that these peculiar eyes might detect that. But, as Van Dover *et al.* point out[3], most animals that are known to use bioluminescence for communication have normal image-forming eyes. Indeed they must have, if they are to determine the directions of small sources of light. Rather than the detection of any conventional source of light, the authors suggest that these structures have a unique function: the detection of the sulphide vents themselves.

It is obviously a good thing for the shrimp to have a way of determining their proximity to a vent. Around the vent there is abundant food, but in it the shrimp would be instantly pressure-cooked. The question is whether or not the vents give off radiation that can be seen. I admit to a deep-seated reluctance to believe that columns of water can glow, related, I suspect, to my knowledge that water is for putting fires out. Nevertheless, the paper by Pelli and Chamberlain on page 460 of this issue[4] has educated me. These authors treat the vent simply as a 350 °C blackbody radiator, and work out how much energy there would be in the part of the spectrum to which the shrimp's visual pigment is sensitive. (Oddly, perhaps, the pigment is a normal blue-green sensitive rhodopsin, not especially sensitive in the red.) After heroic calculations, involving the estimates of pigment density made by Van Dover *et al.* [3], Pelli and Chamberlain conclude that the plumes would be detectable by an 'eye' of this kind, and at a distance of around 2.3 m for a 10-cm-wide vent. Pelli and Chamberlain also do the calculation for the human eye, and conclude that for us the luminance of the vents would be just below threshold — a result that squares with the initially damaging finding that dark-adapted observers in the Alvin submersible could not see them.

Why have the shrimp eyes abandoned their optics? Are such eyes actually better at certain detection tasks? For most vision, resolution is needed and optics are essential. But this may not be so for the detection of a single luminous source. The number of photons that can be captured and counted depends only on the area available to trap them, and this area can consist either of the pupil in an image-forming eye, or an area of naked retina as seems to be the case here. The naked-retina solution has the advantage of compactness; it is easy to fit a large detecting area into the carapace itself, whereas an eye of equivalent area would need to be large and three-dimensional. Provided only the crudest directionality was required, the eye's optics would in any case not be necessary.

If this shrimp, *Rimicaris exoculata*, were the only animal to have lost its optics while retaining the retina I would feel that the story presented in these two papers[3,4] was complete. However, there are actually many other naked-retina eyes among deep-sea animals[5,6]. These include other shrimp, isopods, amphipods, mysids and the famous fish *Ipnops murrayi* that turned up on the bottom of the sea at 3,500 m depth during the first deep-sea *Challenger* expedition of 1873. *Ipnops* has large, slightly concave retinas consisting mainly of rods, and covered simply by a cornea-like plate[7,8].

It is possible that all these animals live near hydrothermal vents, but this seems very unlikely. At these depths the only other use of the eyes would seem to be the detection of bioluminescence, but again, why abandon directionality when it would clearly be useful? The answer may be that these eyes (possibly including those of *Rimicaris*) are actually not quite as non-directional as they seem. A vertebrate rod, with a refractive index of 1.41, will trap light by total internal reflection over an angle of 36°, and a crustacean rhabdom of index 1.37 over 24°. In both cases, a curved array of these photoreceptors with no further optics could constitute an eye that would provide enough resolution for the rough direction of bioluminescent objects to be determined, as well as providing high sensitivity for their detection. It could be that we are dealing here not with naked retinas but with a new type of eye. □

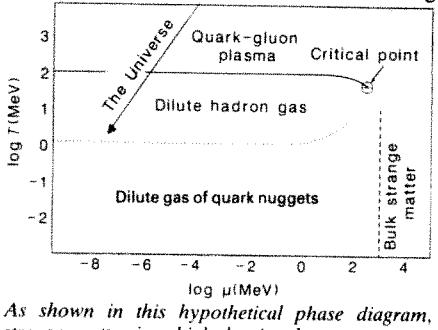
Nuclear physics

Engineering with quark matter

Charles Alcock

THE possibility that small drops of 'quark matter' might be stable was first put forward by Witten[1]. More detailed calculations by Farhi and Jaffe[2] showed that the hypothesis was certainly plausible; also these authors named stable quark matter 'strange matter' because of the important role played by strange quarks, a name which has stuck. The strange-matter hypothesis has several interesting consequences, principally in astrophysics (for a review see ref. 3). Two new papers, that of Brügger *et al.* on page 434 of this issue[4] and one by Madsen[5], address the question of how much strange matter there is in our part of the Universe. And Shaw *et al.* on page 436 of this issue[6] suggest a novel scheme for producing small lumps of strange matter, collecting and then growing the lumps; this is a proposal for engineering with quark matter.



Quark matter is a hypothetical phase in which quarks are not confined in individual hadrons such as the proton (which consists of two 'up' quarks and one 'down') and the neutron (one up and two down quarks), but are free to move about within the phase. Strange matter is a quark-matter phase which contains three flavours of quarks — up, down and strange — and a few electrons. By hypothesis, strange matter is absolutely stable, which means that its mass (energy) per quark is lower than that of iron (which is the most stable ordinary nuclear matter) and cannot decay without violating energy conservation (see figure). This hypothesis is consistent with phenomenological models of the strong interaction, but good first-principle computations of the mass per baryon are not available.

Because strange matter is a bulk phase, it might be found in lumps of atomic mass A in the range 10^2–10^{57}, but with atomic number (charge) Z much less than $A/2$. These positively charged lumps are often known as quark nuggets. They behave chemically as ordinary atoms with the same Z and are, roughly speaking, nonstrous isotopes. A quark nugget may grow by absorbing neutrons; charged particles such as protons are not readily absorbed because of Coulomb repulsion.

For theorists, not being able to recognize the true ground state of the strong interactions (is it iron or strange matter?) is very disturbing. It makes sense, therefore, to search for quark nuggets or use experiments to settle the question. Madsen[5] proposes that observations of pulsars should help. Conventionally it is suggested that neutrons are the stable form of matter in the enormous gravitational field of these collapsed stars, but some argue that strange matter is. For his proposal, Madsen adduces the conclusion of Alpar[7] that the radio pulsars which exhibit glitches (abrupt, very small period reductions followed by a few months of relaxation) must be made of neutron matter, not stange matter. This conclusion rests on the success of neutron-star models for the glitch phenomenon and the absence of a model for glitches in the context of strange matter. Because strange matter absorbs neutrons, one seed of strange matter will convert an active neutron star into a 'strange' star. Madsen's analysis rests on the rate at which these seeds would be accreted from the interstellar medium.

Should they exist in the interstellar medium, quark nuggets will rain steadily onto stars, where friction slows them down. Thus a nugget can become bound to a star. If the star is a neutron star, the nugget will act as a seed which will grow until the entire star is converted to strange matter. Furthermore, if the star is the progenitor of a neutron star (a high-mass normal star which eventually explodes as a supernova, compressing its core to a neutron star), then any nuggets it captures will be present later when the neutron star is made. Madsen shows that this latter process is the most interesting and places limits on the number of quark nuggets in the interstellar medium. This is a model-dependent limit, of course, but it does show how to approach issues of fundamental physics using astrophysics.

A more direct method for seeking quark nuggets has been used by Brügger *et al.*[4], who have adapted Rutherford scattering, bombarding material samples with beams of ^{238}U and ^{208}Pb nuclei. Any back-scattering of the beams by angles greater than 90° indicates the presence of scattering centres (the nuggets) more massive than the projectile nuclei.

As shown in this hypothetical phase diagram, strange matter is a high-density, low-temperature phase (density increases with chemical potential μ). At high temperature, strange matter evaporates into ordinary hadrons (dotted line), much as a solid sublimates into vapour on heating; this transition is not a phase transition. At higher temperature, the hadron gas undergoes a phase transition (solid line) to a hot gas of quarks and 'gluons'. Cosmic or experimental production of strange matter occurs by producing the hot quark–gluon plasma with the hope that rapid cooling will trap portions of the matter in the cold, condensed phase. A detailed mechanism for accomplishing this has not been proposed. (Temperature T in megaelectron volts; 1 MeV ≈ 10^{10} K.) (From ref. 3.)

Brügger *et al.* applied this elegant technique to various natural samples (including a meteorite) and derive upper limits to the abundance of quark nuggets: 1 per 10^{10} for nuggets with $A \approx 10^3$ down to 1 per 10^{14} at $A \approx 10^7$. The technique is less readily applied for higher atomic number because the electrostatic potential of the nuggets is not a simple Coulomb form.

Shaw *et al.*[6] propose a much more direct approach to the study of strange matter. They propose that high-energy heavy-ion collisions of the kind studied in present CERN and Brookhaven National Laboratory experiments might make small quark nuggets. They further describe a scheme for isolating, slowing down and storing nuggets which are produced in the experiment. Any nugget which is captured may then be "grown" by the addition of low energy neutrons. This growth phase releases of order 20 megaelectron volts of energy per captured neutron — potentially a useful source of power, as this is nearly 10 times the energy yield per neutron in a conventional fission reactor. In this regard Shaw *et al.* are proposing a first attempt at engineering with quark matter.

There are uncertainities in this proposal. First, it is not clear that the CERN and Brookhaven experiments do indeed make a quark phase. Second, this phase will contain plenty of up and down quarks but strange quarks are produced only as $s\bar{s}$ pairs, and the strange quarks must separate from their anti-strange counterparts. Third, strange matter is a low-temperature phase and these experiments produce a very hot plasma (see figure). And fourth, the isolation scheme proposed looks for negatively charged nuggets, whereas strange matter is almost certainly positively charged in its most stable form.

Despite these reservations, the proposal does not seem to be an expensive addition to experiments that are already in progress. As the payoff in physics would be so large if strange matter were detected, the ideas should be further explored. And the new engineering ideas raise interesting long-term prospects for energy generation. □

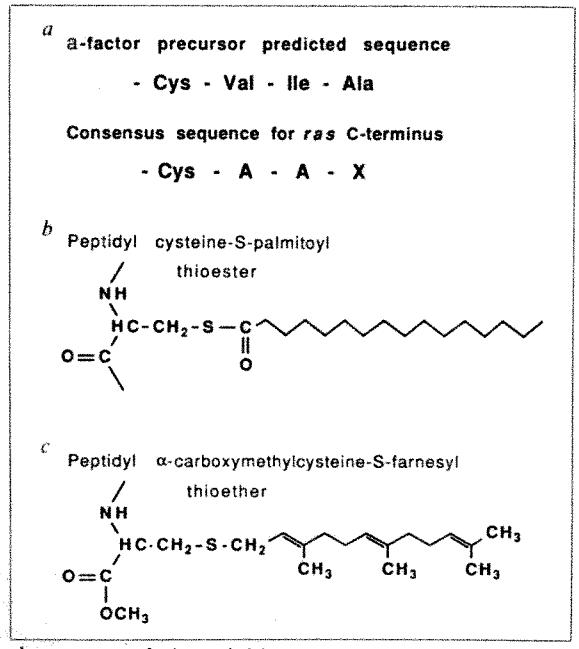
Peptide structure

Beyond transcriptional events



Anthony M. Treston and James L. Mulshine

PROTEIN chemistry, the demise of which was predicted in a News and Views article[1] 10 years ago, is still an essential technique for determining protein structure. Robert Anderegg and colleagues in the December 1988 issue[2] of the *Journal of Biological Chemistry*, for example, report the structure of a yeast mating pheromone using conventional protein-chemistry techniques. Their results demonstrate that, given the present lack of understanding of the mechanisms and control of post-translational processing, the prediction of processing events solely on the basis of nucleic-acid sequence data is speculative in the absence of supporting protein chemistry data.

The traditional approach for determining the structure of peptides and proteins has been through what could be called classical analytical methodology, including purification, derivation, hydrolysis and amino-acid characterization. Recently, however, these approaches have lost popularity because of the speed and precision of sequencing nucleic acids, enabling the prediction of the order of amino acids directly from DNA and RNA sequences. This 'molecular biology' approach to protein chemistry, although accurate, is confined to deriving the linear order of common amino acids in polypeptides.

Many peptides and proteins, however, contain amino acids which have been modified in various ways after translation from their messenger RNA, and these modifications cannot be derived directly from the primary structure of the gene. These post-translational modifications are essential for the biological function of the mature polypeptide, and both the types of modifications and the mechanisms by which they occur are apparently highly conserved across species ranging from yeast to man. The conservative nature of these modifications has allowed the determination of precursor protein consensus sequences which become the substrates for the post-translational processing reactions producing the mature molecule. The ability to predict polypeptide sequence from the primary nucleic-acid structure, coupled with knowledge of characteristic processing mechanisms, can in theory lead to the prediction of the mature processed form of polypeptides directly from a nucleic-acid sequence. But Anderegg *et al.*[2] demonstrate that a consensus sequence alone is not necessarily a reliable predictor of the structure of a mature peptide.

The nucleic-acid sequence encoding the mating hormone called a-factor from the yeast *Saccharomyces cerevisiae* has been known since 1985. The predicted precursor prohormone has at its carboxy terminus the sequence . . . Cys-Val-Ile-Ala, consistent with the consensus sequence for the acylation of the carboxy terminus of *ras* genes (*a* in the figure; sequences summarized in ref. 3). The identity of these sequences suggests that yeast a-factor should undergo the same post-translational processing as the yeast *ras*-related proteins. Furthermore, to exert their activities as regulators of cell proliferation, *ras* proteins must be inserted into the cellular membrane, and a similar mechanism has been postulated to be necessary for a-factor activity[3]. Membrane insertion occurs only for *ras* proteins that have been modified at the cysteine residue near the carboxy terminus by conversion into a thioester of palmitic acid[4]. These considerations all point towards identical post-translational modifications for *ras* proteins and a-factor, that is, conversion to a palmitate cysteine-thioester (*b* in the figure).

In fact, a yeast gene has been identified on the basis of being involved with the processing of both *ras* and a-factor. *RAM* (for *ras* and a-factor maturation function) was described[5] in 1986, and is essential for sexual activity of a-type haploid yeast and for the palmitate esterification and membrane localization of *ras* proteins. It was originally proposed that the *RAM* gene encoded an acyltransferase, with the *de facto* corollary that both a-factor and *ras* have the same cysteine-thioester modif cations. A gene called *DRP1* has no been shown[5] to be responsible for a pos translational processing step occurrin before fatty-acid alkylation of *ras*[5]. *DRP* turns out to be identical to *RAM*.

The data of Anderegg *et al.*[2] now unequ vocally show that the cysteine modifica tions of *ras* and a-factor are not identical or even similar. These authors purifie a-factor from *S.cerevisiae* and establishe by proton nuclear magnetic resonance an mass spectrometry that the biologica activity of a-factor results from a pair c closely related post-translationally modi fied peptides with a carboxy-termina α-carboxymethylcysteine-S-farnesyl ethe (*c* in the figure). Farnesol, a branched chain, polyunsaturated hydrocarbo alcohol, is best known as an intermediat in the biosynthesis of cholesterol an related molecules. The presence o a farnesyl moiety as a cysteine-S thioether *per se* is not unusual, as i is known to be a component of pep tide pheromones from other fungi Not only is the alkyl group of a-facto an unsaturated branched-chain alco hol, whereas the *ras* protein has a saturated linear fatty acid moiety but the chemical linkage is differen in each case; a thioether for a-facto and a thioester for *ras*. These finding are totally incompatible with the pre dicted identical modifications postu lated on the basis of identical carboxy terminal precursor sequences.

In retrospect, the incorrect predic tion of the nature of the a-facto modification and the identity of th protein encoded by *RAM* were caused by reliance on the 'molecula biology' approach to predicting pep tide structure. The *RAM/DRP1* gene described by Powers *et al.*[5] is obvi ously not an acyltransferase acting on both *ras* and a-factor. It seems more likely tha *RAM* encodes a carboxypeptidase o endopeptidase responsible for removal o the tailing A-A-X amino acids of both precursor molecules to provide a free cysteine for modification. Alternatively *RAM* could encode an enzyme respons ible for the methylesterification of th α-carboxy terminus of both peptides. The assignment of a function for *RAM* is an illustration of the need for direct deter mination of peptide structures to resolve the nature of proposed post-translational modifications. □

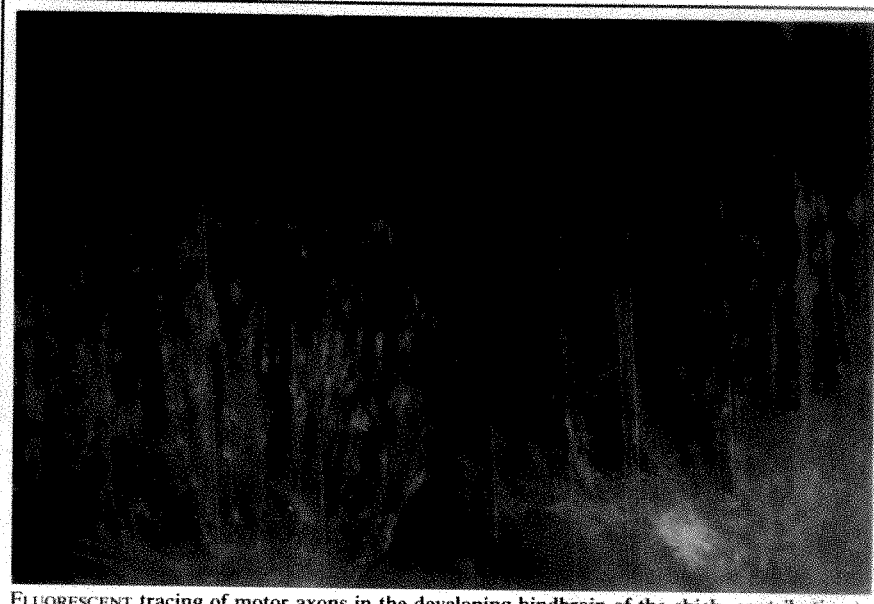
Biochemistry

A protein with many functions?

R. B. Freedman

A QUIZ for the New Year. What is the connection between : (1) a gene product associated with visual transduction in the fruitfly *Drosophila*; (2) the major high-affinity binding protein in vertebrates for the immunosuppressive drug cyclosporin; and (3) an enzyme catalysing a rate-determining isomerization in protein folding *in vitro*? The answer, in two papers on pages 476 and 473 of this issue[1,2] and in a forthcoming paper[3], is that they seem to be the same protein. What this identity means will take some time to work out, because the protein, from whichever direction it is defined, is not yet securely identified with any specific physiological function. But the fact that it catalyses the *cis–trans* isomerization of peptide bonds involving the prolyl residue — the rate-determining step for the refolding of some proteins from the unfolded state — makes it tempting to look for crucial protein-folding processes in the immune response and in visual transduction.

Fischer *et al.*[1] and Takahashi *et al.*[2] in their papers in this issue have reached this point by asking essentially the same question. Both groups were attempting to characterize further the peptidyl-prolyl *cis–trans* isomerase (PPI) which the former group has identified and shown to be an abundant cytosolic protein[4]. PPI catalyses isomerization of the stereochemistry about the imide bond in the sequence -X-Pro-, both in small model peptides and in proteins, and in some proteins the result is catalysis of folding from the denatured to the native state.



Fischer *et al.* have now identified[1] the 38 amino-terminal residues of porcine PPI using automated amino-acid sequencing. They find that this sequence is identical to the published amino-terminal sequences of cyclophilin from human and bovine sources. Cyclophilin was identified in 1984 as an abundant and widespread mammalian protein which binds with high affinity to the fungal product cyclosporin A, a cyclic peptide of 11 residues which is a powerful suppressor of the immune response. Because of the similarity of amino-terminal sequences, and of other properties such as molecular mass and amino-acid composition, Fischer *et al.* propose that PPI and cyclophilin are identical.

This proposal is confirmed by Takahashi *et al.*[2], who performed a complete protein-sequence analysis of PPI based on automated sequencing of peptides produced by trypsin, cyanogen bromide and V8 protease. Their results show that porcine PPI is identical in sequence to bovine cyclophilin and almost identical to human and rat cyclophilin, whose structures have been derived from the complementary DNA sequence.

Both groups[1,2] have pursued this surprising result to examine functional relationships between the enzymic activity of PPI and the binding activity of cyclophilin. They point out that previous results show both activities to be heat-sensitive, abolished by trypsin treatment and sensitive to modification of -SH groups. They now find that the presence of cyclosporin A inhibits the isomerase activity of PPI/cyclophilin and that the isomerase activity towards both peptide and protein substrates is completely inhibited by cyclosporin A at concentrations below 1 μM. Fischer *et al.* estimate an inhibition constant of below 10 nM, which is in the range reported for the dissociation constant of cyclophilin for cyclosporin A, as measured in studies of the direct binding. It is thus possible that PPI/cyclophilin is not just a high-affinity binding site for cyclosporin A, but is also the site of the drug's primary biological effect — the inhibition of the enzymic activity of PPI.

Where does visual transduction in *Drosophila* come in to all this? Charles Zuker and colleagues have been analysing the mechanism of visual transduction by characterizing mutations which affect this process in *Drosophila*. They constructed a library enriched for genes encoding proteins preferentially expressed in the adult visual system, and hybridized clones isolated from this library to polytene chromosomes to determine their positions on the cytogenic map. One of their clones (λ322) maps to the position 21D4-E2, within the position of a known visual transduction gene *ninaA* (located at position 21D3-E2 by conventional genetic mapping). The phenotype of the *ninaA* mutant is a drastically reduced level of the visual pigment rhodopsin, but there is no reduction in opsin expression. The mutation is therefore thought to affect post-translational modification of opsin or its degradation. By any criterion this is an interesting mutation, and it would be intriguing to know the nature of the *ninaA* gene product. Zuker and colleagues[5] now present the sequence of their clone λ322, and the inferred sequence of the *ninaA* gene product. This protein comprises 237 residues, and its central 180 residues are almost identical to cyclophilin/PPI; bovine cyclophilin/PPI has more than 40 per cent of the amino-acid residues, in common with the *Drosophila ninaA* protein, and conservative substitutions account for more than 30 per cent of the remaining residues. Given the taxonomic distance involved, the similarity is striking.

Taken together, the new reports identify an intriguing protein or protein family. In vertebrates, cyclophilin is clearly the main high-affinity binding site for cyclosporin A, and is thought to be its primary site of action; this action is not well-defined, but

FLUORESCENT tracing of motor axons in the developing hindbrain of the chick, contributing to evidence that growing nerves in this region respect segmental boundaries that may be analogous to those that define the body pattern of *Drosophila* during development (see the paper by S. Lumsden and R. Keynes on page 424 of this issue). The boundaries of the segments are preferentially stained with anti-laminin antibodies while the more central regions show preferential expression of the embryonic neural cell-adhesion molecule N-CAM. Strikingly, similar boundaries seem to be observed in the early embryonic mouse hindbrain by the expression of the zinc-finger gene *Krox*-20, which is expressed in alternating segments in the same region (see the paper by D. G. Wilkinson *et al.* on page 461 of this issue). □

it appears that cyclosporin A interrupts an early event in the antigenic activation of T-helper cells, leading to production of lymphokines. The new work shows that this protein is identical to the enzyme prolyl-peptidyl *cis–trans* isomerase, but the physiological function of this enzyme is not known. The presence of a closely related protein modifying the properties or stability of the visual pigment in insects raises a whole further set of questions. The power of gene and protein sequencing and the use of sequence databases have here connected three apparently disparate lines of work[1-3]. Now, more conventional studies on the properties of PPI, and on the roles of cyclophilin in the immune response and of the *ninaA* product in the visual system, will be needed to make sense of that connection in functional terms. □

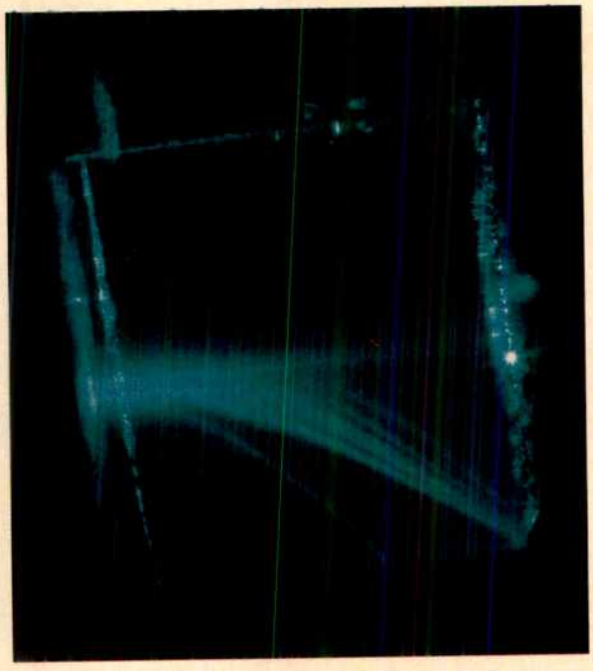
Optical computing

Polymers that make light work

Paul Calvert



THE prospect of computing with light rather than electricity is attractive because light pulses travel faster in glasses than electrical pulses in metals, and light transmissions are less vulnerable to interference from outside, or from cross-talk between adjacent wires. At a recent symposium*, workers showed that they are close to developing polymers suitable for use in applications such as optical switches.

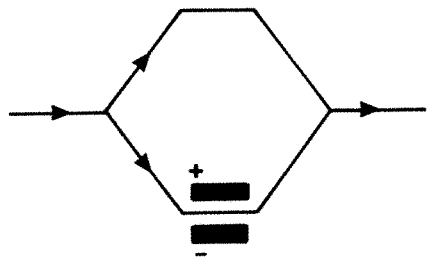
To make an optical computer, one needs ways of switching light beams on and off, or of diverting them between different paths. This requires a material whose refractive index changes either as a function of light intensity or as a result of an applied electrical field (see figure). The first effect would make it possible to build an all-optical computer, the second to use light to couple different parts of an electronic computer — an internal expressway. Conjugated organic molecules (with alternating double bonds) have large values of the important nonlinear optical coefficients and, although the simple compounds tend to give poor films, the equivalent polymers are readily processed into thin films for integrated optics.

The basic equation governing the nonlinearity is

$$P=\chi^{(1)}E+\chi^{(2)}E^2+\chi^{(3)}E^3 \ldots$$

where the polarization of the material P depends on the applied electrical field E to a series of powers. E can also be the oscillating electric field of light, in which case the first coefficient $\chi^{(1)}$ is related to the usual refractive index. The subsequent coefficients tend to be very small and so become important only with intense light, such as emitted by lasers. Although I will discuss them as simple coefficients, $\chi^{(1)}$–$\chi^{(3)}$ are tensors whose values are dependent on the directions of the input and output fields; $\chi^{(2)}$ is a third rank tensor (a three-dimensional array) and workers in the field are not yet ready to tackle the problem of defining the whole set (up to 27) of coefficients.

Bending light. The electric field of a laser beam induces changes in the refractive index of a barium titanate crystal which in turn bend the laser beam. Increasing the field intensity changes not the degree of bending, but rather the onset time for the effect, which is non-zero. (Courtesy of Malcolm Gower, Rutherford Appleton Laboratories.)



Consider the molecule as an organ pipe. It vibrates when excited by a beam of sound, even if the frequency is not the natural one of the pipe. A crystal is a room full of such pipes, regularly spaced. Sound travels more slowly through this than through air alone, as each pipe stores some vibrational energy and then gives it back. As the sound level is increased, the pipes become nonlinear and produce more overtones. The amount of second and third harmonic depend, through $\chi^{(2)}$ and $\chi^{(3)}$, on the properties of the pipes and their arrangement. Effects of $\chi^{(2)}$ will cancel out in a random or centrosymmetric arrangement of pipes.

The materials' requirements are: a big coefficient $\chi^{(2)}$ or $\chi^{(3)}$, no absorption of the light and little scattering so that as little light as possible is lost in each device, a fast response and easy processing into thin films. The material to beat is lithium niobate, which may turn out to be as ubiquitous in integrated optics as silicon is in electronics. At present it is damaged by the high intensities needed for all-optical switching, and although electro-optic switches can be made (see box), they are rather large because a long path between the electrodes is needed to produce sufficient effect on the light, and the response is rather slow. For a fast response, the effect must depend purely on the molecular electronic structure, anything involving atomic or molecular motion being too slow.

Crystalline, asymmetric organic materials exist with very high $\chi^{(2)}$ coefficients, for example 2-methyl-4-nitroaniline. The problem is that the crystalline films tend to scatter light at the grain boundaries, they are weak and they evaporate. Such compounds can be incorporated into amorphous polymers to give a relatively tough transparent film, but $\chi^{(2)}$ is zero unless an asymmetric structure can be induced. This can be done by applying a strong field across the film to align the active groups but the effect is still weak. Working electro-optic devices have been made from these polymers. At the recent meeting, J. Stamatoff, of Hoechst Celanese (which leads the field) described a polymer electro-optic switch that worked at volts but was 1.3 centimetres long. That is enormous by current computer standards.

Another approach is to forget $\chi^{(2)}$ and look for a large $\chi^{(3)}$, for which no molecular alignment is needed. Favoured materials are highly conjugated polymers. The extensive π-orbital systems make these the electronic equivalent of a rubber organ pipe and large $\chi^{(3)}$ values (around 10^{-} e.s.u.) have been measured for both polyacetylene[1] and the polydiacetylenes. The chief problem with polyacetylene is that it is black and so absorbs most of the

* *Materials Research Society*, Boston, 28 November–3 December 1988.

Pictured right is a Mach-Zehnder interferometer, one of several proposed switching devices[7]. Light is guided through a 1-micrometre channel between walls of slightly lower refractive index. The beam is split between two legs one of which has two electrodes above and below. Applying a voltage changes the effective refractive index in that channel so that the light slows until it is exactly out of phase with the other leg: when the beams are recombined, nothing emerges. This can convert electronic data to light pulses for transmission between parts of a computer that are too far apart for electronic conduction to occur rapidly. A similar logic device could have one leg intrinsically nonlinear such that the light in that leg slows as the intensity increases until it becomes out of phase with the other leg. This could then be part of an all-optical computer. The small channel size allows very high light intensities to be reached with relatively low total powers.

signal, but it is also intractable and unstable. As $\chi^{(3)}$ increases with the extent of conjugation to the fifth power, long conjugated chains should have huge values. Unfortunately these systems also absorb light.

The polydiacetylenes are coloured but transparent at long wavelengths and some can be cast as films from solution. They can also be prepared as Langmuir–Blodgett films (similar to soap films), but these tend to include light-scattering defects and the optically active groups are diluted by the soluble hydrocarbon tails needed at the processing stage.

Polybenzbisthiazole (PBT) also has a $\chi^{(3)}$ of around 10^{-10} e.s.u. (ref.3; Prasad, State University of New York, Buffalo). This is one of a group of rigid rod polymers developed from work at Wright Patterson Air Force Base on high-temperature polymers. Polyphenylenevinylene is another black, conjugated, conducting polymer and has $\chi^{(3)}=3\times10^{-10}$ e.s.u. when drawn into an oriented film.

The polysilanes, based on a silicon backbone rather than carbon, are an interesting possibility[4,5]. For polymethylphenylsilane $\chi^{(3)}=10^{-12}$ e.s.u. when measured with 1.06-micrometre light and decreases at longer wavelengths as the third harmonic is enhanced by resonance. Polysilanes are clear and can be easily made as films. They would be expected to have just a σ-bond system similar to polyethylene and no significant nonlinearity. The effect seems to arise from delocalization of electrons along the silicon-chain backbone which allows enough 'softness' to respond to the optical input. There is some evidence for this delocalization in the optical spectrum[6]. Also new data show that the response is very fast (taking less than 3 picoseconds) and is therefore due to electronic motion rather than molecular motion or thermal effects[5].

One expects the nonlinearity of an organ pipe to increase as the resonant frequency is approached and it starts to shake vigorously. In molecules resonance is usually associated with absorption and so is to be avoided. If the aim is to generate third-harmonic light, there should be no absorption at either the fundamental frequency or at the third harmonic. But to obtain a simple change of refractive index absorption at the third harmonic can enhance $\chi^{(3)}$ without detracting from the transmission of the fundamental. In general the measured $\chi^{(3)}$ rises as the fundamental wavelength is reduced until the third harmonic approaches an absorption band. In other words, absorption seems to be the price of a high $\chi^{(3)}$. Much attention was given at the meeting to molecular orbital calculations of $\chi^{(3)}$ which now can get within an order of magnitude of the right answer. We may be approaching a point where some useful prediction can be made of good structures.

Large inorganic crystals are already used for frequency doubling and tripling for laser spectroscopy, but these materials are difficult to adapt to small waveguides. Organic materials with extended conjugation offer large nonlinear coefficients and rapid switching when compared to inorganic materials. Polymers can be stable, easily formable and can (with difficulty) be made to high optical transparency. Whether these properties can all be combined in a single system remains to be seen. One view is that the stringent requirements of purity and stability in a computing system will prove to be too much for organics, as seems to be the case with conducting polymers. Another view is that opto-electronic transducers have been functioning effectively in chloroplasts and retinas for a long time and there should be no problem. □

Nature statistics

In 1988, about 6,000 unsolicited manuscripts were submitted to *Nature* for publication as Letters or Articles — almost exactly the same number as in 1987. About 35 per cent were sent to our Washington office rather than to London — there is no preference. About 30 per cent dealt with physical sciences rather than biological sciences. As usual, submissions peaked in the summer months to coincide with the period when potential referees (and *Nature* staff) are most likely to be away.

Of the submitted papers, just over 1,000 were published, 400 in the physical sciences and 600 in the biological sciences. If 1988 is no exception to the pattern of the past few years documented by the *Science Citation Index*, 30 of the 600 biological papers will be among the 100 life-science papers published in 1988 most cited by the end of 1989.

On the average, the delay between receipt and the appearance in print of the papers accepted for publication was just over 4 months. (Papers not accepted for publication are returned to their authors much more quickly.) As the figure shows, 30 or so papers, mostly on high-temperature

superconductivity, were published within 6 weeks of submission, but an equal number took more than 8 months to appear in print — sometimes because they were over-generously granted the original date of submission despite long delays during substantial revision. The median time between receipt and acceptance was 10 weeks, and from acceptance to publication was 7 weeks.

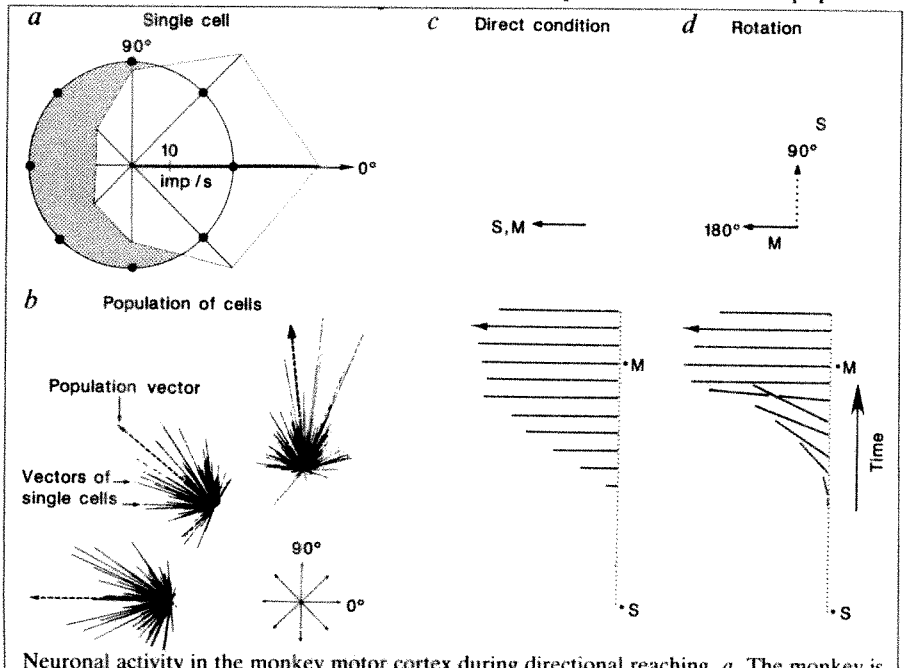
Naturally, we hope that publication will be even faster in 1989. One helpful development is the increasing use being made of telefax machines. For example, the proportion of referees' reports sent to our Washington office by that means increased from 8 per cent in June 1988 to 35 per cent in December. During 1989, we expect a further increase in the use of fax machines and some growth in the use of electronic mail to deliver reviews of manuscripts. □

Neuroscience

Cognitive control of movement

Roger Lemon

RECORDING from single cells in conscious animals has the potential to provide direct insights to the working brain. Investigation of cerebral events associated with movement using this approach has shown that cells in different areas of the cerebral cortex are involved with different aspects of movement performance[1]. Now, Georgopolous *et al.*, in the 13 January issue of *Science*[2], make the exciting claim that studying the activity in populations of cortical neurons can allow visualization of the cognitive processes preceding movement. These new results raise important issues about the central processing that occurs within the motor cortex before movements are executed.



Georgopoulos *et al.* use mental rotation[3] as an experimental test of cognition in a rhesus monkey. In this procedure, the monkey is rewarded for making a movement at an angle to a target light whose position is changed from trial to trial. This process has been extensively investigated in humans[4,5], and it has been suggested that subjects solve the problem by mentally rotating an imagined movement vector from the direction of the stimulus to that of the required movement.

Georgopoulos and his collaborators have already shown[6] that the direction of movement is represented in the monkey motor cortex by the neuronal population vector (see figure legend). This concept is attractive because it concerns the contribution of a whole population of cells, rather than of individual neurons. In their new study[2], Georgopoulos *et al.* recorded the activity of single cells in the motor cortex during performance of the task and computed the behaviour of the population during the reaction time. They find that the information content of the population vector is greater than would be required to explain reaching performance in humans[7].

An important feature of the population vector is its predictive value. Mos neurons in the motor cortex are activ before the movement is performed, an the direction of the population vector is good indicator of the direction of th upcoming movement. Georgopoulos *al.*[2] trained the monkey to move eithe directly towards any one of eight targe lights (*c* in the figure) or at 90° in an anti clockwise direction to the light (*d* in th figure). When the monkey moves directl to the light, the population vector point towards the direction of the movemen from about 125 ms after the target wa illuminated; in the rotation condition, th vector first points in the direction of th stimulus light, and then begins an anti clockwise sweep until, at about 225 ms the vector points in the direction of th required movement.

Georgopoulos *et al.* claim that this rota tion of the vector is the neuronal equiva lent of the cognitive operation carried ou by human subjects performing the sam task. They point out that anticlockwis rotation of the vector (through 90°) i much quicker than in the opposite, clock wise direction (270°) and allows th monkey to solve the task quickly. Th speed of vector rotation in this overtrainec monkey was 732° per second, which i somewhat faster than the speed at whicl human subjects can perform the task[5] Remarkably, the reaction time was th same for both conditions (260 ms after th target light was switched on). Thus in th rotation condition, only 35 ms elapsec between attainment of the 'correct' direc tion by the population vector and th onset of the appropriate arm movement.

Hierarchical notions of movemen control imply that other, 'higher' brai structures, which project to the moto cortex, are involved in the cognitive operations needed to solve the menta rotation task. But the new results show that motor-cortex activity reflects these operations apparently throughout the preparatory period, and that the moto cortex does not receive only the fina command to move (for if it did, the vecto would not rotate, but it would already be pointing in the appropriate direction wher it appeared). It is perhaps surprising to find evidence for these operations in the motor cortex, which has long beer thought of as an executive structure in

Neuronal activity in the monkey motor cortex during directional reaching. *a*, The monkey is trained to move a lightweight handle from the centre of a table to one of eight target lights (dots) located at the edge of the working surface at 45° intervals. **Single cells** discharge for reaches in all eight directions, but are most active for one preferred direction (length of lines in *a* indicate mean firing rate during the reach). *b*, The broad 'directional tuning curves' of single cells make it unlikely that individual neurons code precise movement direction. But **populations of cells** could: *b* shows the vector contribution of the activity of a large number of single neurons; line length indicates discharge frequency. The **population vector** (dotted line) can be thought of as the sum total of discharges or 'votes' contributed by all the directionally tuned cells in the population; most votes will be cast by those neurons for which the required movement is in their preferred direction. The population vector points in the direction of the movement[6]. *c*, *d*, Temporal progression of the vector from the time the target light is switched on (S) to the onset of the reaching movement (M). The cells first become active about 125 ms after S, and movement begins at 260 ms. For the condition in which both stimulus and movement are in the same direction (*c*), the vector points in the required direction at all times. For the alternative condition, where the monkey must move in a direction of 90° to the stimulus (*d*), the vector first points in the direction of S, then rotates until, at about 225 ms, it is pointing at M (from refs 2,6).

movement control, an idea enshrined in the use of the term 'upper motoneuron' in clinical neurology.

The functional linkage of the cells sampled by Georgopoulos *et al.* to the muscles producing the reaching movement is unknown. The weighting given to all cells in the population vector is equal[6], although it is known that some of these cells are probably interneurons and others are output neurons, projecting to the brainstem and spinal cord. It is also paradoxical that the time delay between discharge of even these output neurons and the onset of muscle activity can be more than 100 ms, yet the descending pathways from the motor cortex to shoulder muscles can be traversed in a tenth of that time[8]. Discharge of these cells can also be dissociated from movement, because the introduction of a waiting period into the experimental protocol allows the vector to be seen without movement[9]. □

Cosmology

The elusive anthropic principle

Marek Abramowicz and George Ellis

THE anthropic principle is a modern attempt to deal with a question as old as mankind: why are we here? It is posed in the particular sense: why does the Universe seem to have special and very peculiar properties supporting our existence? Is this by pure chance, or is there an underlying reason, a purpose, perhaps a special design? Although the participants at a recent meeting* were hard pressed even to agree on what is the appropriate way to approach the question, there was one proposal that observations of the homogeneity of the Universe could be used as a concrete test of a particular variety of the anthropic principle.

The notion of an anthropic principle arises from the peculiar circumstances that must occur for life to evolve during the lifetime of a universe. For example, the natural constants in our Universe not only allow for the existence of stable atoms from which matter is formed, but also (together with proper initial conditions of the Big Bang) lead to the formation of galaxies and stars, apparently vital features of life. The task that those interested in the anthropic principle have set themselves is to reformulate, in a useful way, the questions of whether this a fortunate coincidence, inevitable or even just to be expected.

It was apparent from the discussions that even this raises considerable controversy. Some participants maintained that the whole issue is not a real scientific question; others that it is a key issue in cosmology. It was clear, particularly during informal discussions, that this controversy has a philosophical as well as a scientific nature: opinions are based not only on the speakers' scientific knowledge or extrapolations thereof, but also to a great extent on their *weltanschauung* (world view).

L. Gratton (Rome University) was one of the few who argued that the anthropic principle is meaningless. This was an attack on the strong version of the principle rather than the weak one (see below). F. Hoyle (University of Wales) argued that far from being meaningless, the principle supports the steady-state theory of the Universe; and G. Coyne (Vatican Observatory) argued that it supports (or at least is congruent with) the existence of God. Although these, and several other, philosophical interpretations were all analysed extensively, the main debate at the meeting took place on more physical grounds, between the supporters of the strong anthropic principle and those of its weak version.

The strong anthropic principle claims that the Universe must admit intelligent life, not by chance but of necessity. The weak principle stresses that we, as intelligent observers, may see (and do see) some apparently very special properties just because of the selection effect: intelligent life can only develop in particular places and at particular times. The issue, on this view, is to determine what restrictions this implies. Most participants came out against the strong principle and for the weak one. Interestingly, J.D. Barrow (University of Sussex), co-author with F.J. Tipler of the stimulating book *The Anthropic Cosmological Principle* (Oxford University Press, 1986), seems to have abandoned the strongest version expressed in that book, the final anthropic principle: not only must life come into being in the Universe, but it must then persist to the very end.

B. Carter (Paris Observatory), largely responsible for the renewed interest in the theme, was mainly concerned to argue the indisputable nature and power of the weak version of the principle. He points out that some appearance of a purposeful direction in biological evolution is entirely predictable (without invoking any mysterious design mechanism) provided one bears in mind that in addition to the darwinian effects of natural selection one should also take into account the anthropic effect of self-selection; our observations are biased by the fact we live in a Universe where intelligent life has indeed come into being. Our failure to observe the type of alternatives in which intelligent observers are proscribed, self-evidently cannot mean that there is no chance of such alternatives occurring. Their existence is tautologically unobservable.

H. Reeves (Saclay) developed implications of this theme, looking at conditions for the emergence of complex structures in the Universe (a necessary pre-requisite for the emergence of life). The emphasis in this approach is very much a physical one, relating to the formation of such complex structures according to the known laws of physics. Thus both Carter and Reeves played down the question of what would happen in other universes with other laws of physics (the kind of issue raised in discussing the strong version).

Perhaps the strongest defender of a version of the strong principle was D.W. Sciama (International School for Advanced Studies, Trieste) who argued that there are three possibilities: life can occur through pure chance; because of some purposive design (God); or because all possibilities occur in some ensemble of universes that includes those where life can occur and others where it cannot. Sciama's thesis is that what is not forbidden is compulsory; that is, all logically possible universes must occur, disjointly from each other. In a sense this incorporates into cosmology Dostoevsky's remark: "If there is no God, everything is allowed."

The most surprising part of Sciama's argument is a suggestion that, although the other universes are all causally disconnected from the one we live in (and between themselves), there is a possible observational test to support the hypothesis of their real existence. Essentially, his argument is that if all logical possibilities occur, then our Universe should be no more special than needed; another universe with only slightly different properties would also be sufficiently special to support intelligent life.

Thus some of the properties of our Universe should be random in the above sense, or at least not particularly special. Hence we expect to find, with accurate enough measurements, some assymetries in the Universe that do not accord, for example, with Penrose's assumption of isotropy ('conformal flatness') at the Big Bang or Hawking's proposal of a particular special set of boundary conditions on the wavefunction of the Universe which imply both initial isotropy and homogeneity. He would regard his thesis as satisfied when initial anisotropies (which

The Anthropic Principle, Venice, 18–19 November 1988.

in principle can be estimated from measurements of anisotropies in the cosmic background radiation) are found to be greater than predicted by these special geometries.

This is certainly a controversial viewpoint; apart from the questions it raises philosophically, it needs technical development to be made precise enough for verification. In fact, it eventually leads to the major unsolved problem of a probability measure on the initial conditions for the Universe, without which all this kind of speculation is on shaky ground. □

Marek Abramowicz and George Ellis are at the International School for Advanced Studies, 34014 Trieste, Italy.

Palaeoclimate

Finer grains of truth

Peter D. Moore

POLLEN analysis of organic peats and lake sediments is used extensively to reconstruct past changes in vegetation and climate. But such studies have concentrated mainly on changes detectable on a timescale of centuries or even millenia. Changes over timescales of a few decades or less are usually considered too fine to be resolved by the technique. But several recent projects show that this is not always so: Green and co-workers[1,2] for example, not only show that fine-resolution analysis is possible, but also relate it to environmental variables such as short-term climatic fluctuations and fire frequency.

Several problems stand in the way of fine-resolution pollen analysis. In many lakes, sediment is resuspended and redeposited during periods of turbulence[3]: it can even be 'focused' into certain parts of the basin[4]. These processes mix materials over a period of years and, although the general trends in the fossil record may be preserved, short-term changes are masked and smoothed. In peat deposits, the main problem is one of pollen migration within the loosely packed upper layers of the growing peat mass. Experiments in which pollen is added to columns of peat suggest that vertical transport with water flow limits the resolution potential of the analysis[5].

Despite these concerns, some studies both on lake sites and in peat deposits do permit fine-scale resolution. In deep, steep-sided lakes, resuspension may not be significant and sediments can even develop annual laminations, demonstrating the stability of sedimentation. In peats, several studies involving close sampling, even in poorly compacted layers, show a pollen stratification that argues against vertical pollen migration. Van Geel and Middeldorp[6] have now analysed the stratigraphy of freshly formed peat in Carbury Bog, Ireland, which shows strong peaks in pollen from Ericaceae, Gramineae and *Pinus* in the top 10 cm of unconsolidated peat, formed over the past 10 years. If there were significant downwash of pollen through the upper peat layers, these peaks would have been lost.

Green and colleagues have developed techniques of comparing such fine-scale pollen changes with fluctuations in environmental factors in peat[1] and in lake[2] sites. By looking at the sequential records of pollen, charcoal and (independently obtained) rainfall data as time series, they can cross-correlate the data sets and also allow for lag times between the causative factor and its response in the pollen record. They find that certain pollen taxa, *Eucalyptus*, grasses and Compositae (Tubuliflorae), show a strong positive response to rainfall, and that even small variations in rainfall are reflected in the pollen stratigraphy. These are also correlations with charcoal deposition. *Eucalyptus*, for example, responds positively with a 5–10-year lag phase, suggesting that trees damaged by fire had recovered rather than being destroyed.

But the relationship between pollen and charcoal is complicated by problems of soil erosion and consequent enhanced pollen input following a fire. And the origins of the charcoal itself must be considered: Clark[7] has examined charcoal transport in relation to particle size and considers that fine particles (such as those found on microscope slides for pollen preparations) are transported over long distances and do not necessarily reflect fires in the immediate catchment. So correlations between pollen and charcoal must take into account the dispersal characteristics of both pollen grains and carbon particles.

These recent studies indicate that the technique of pollen analysis, both of peats and certain types of lake sediments, does have potential in providing fine-resolution information concerning vegetation changes and hence the variation of other environmental factors in time. □

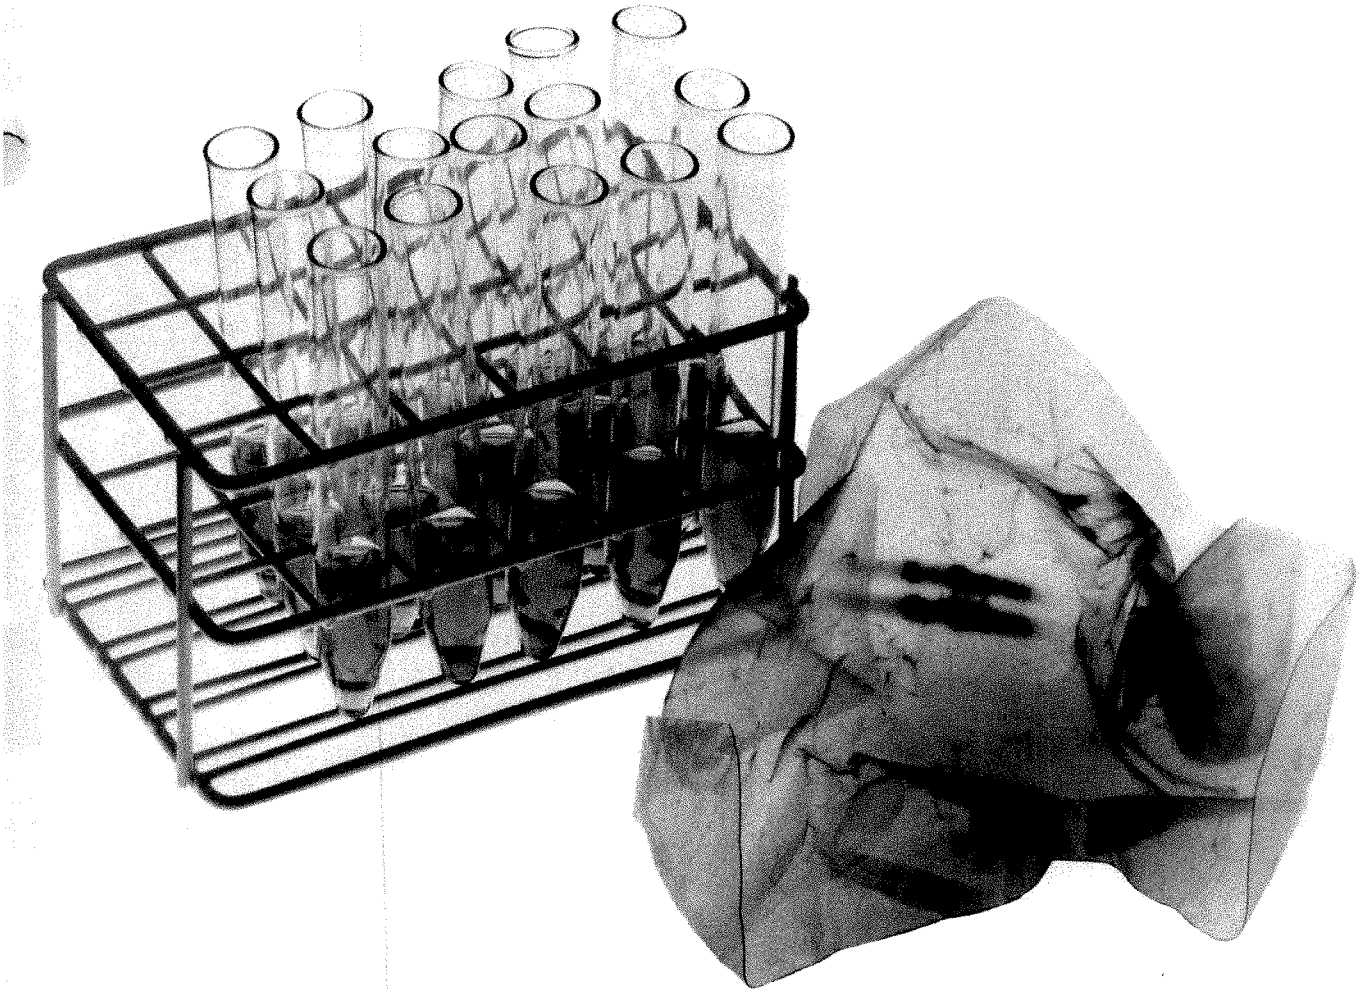
Daedalus

Diamonds forever



BRITTLE fracture is the ultimate engineering catastrophe. Microscopic cracks lurk in all solid surfaces; they gape slightly under load, and may even extend a little. Sooner or later the component may meet a stress great enough for a crack to run away, like a cloth tearing in two from a nick in one edge, and disaster strikes.

Now Daedalus has the answer. When a microcrack forms or extends, the local chemical bonds are pulled apart, leaving two pure free-radical surfaces. Such reactive faces must combine almost instantly with local air and water. But, says Daedalus, suppose the atmosphere around the crack were not air, but a polymerizable gas such as ethylene? Each radical-covered surface would be a splendid heterogeneous polymerization catalyst: the crack would be instantly bonded with polyethylene.

But polyethylene is not really an ideal 'glue'. Daedalus recalls that methane–hydrogen mixtures can deposit a tenaciously bonded diamond film on surfaces hot enough to decompose the methane to methyl radicals. A fresh crack surface dense with free radicals should do this even in the cold, by direct electron-transfer. A crack formed in a methane–hydrogen atmosphere should be instantly sealed with strong, stiff, inert, non-melting diamond: the finest imaginable engineering glue.

So Daedalus plans to 'crack-proof' industrial structures such as cranes, bridges and pylons, by slowly stressing them up to working load in an atmosphere of methane–hydrogen. As each microcrack in the structure opened up, it would be automatically sealed with diamond. When the structure finally reached its design load, each stressed part would be studded with tiny diamond inclusions: closing all its potentially deadly little cracks, and pre-stressing it perfectly to its service duty. Even structures like airframes, plagued by the growth of fatigue cracks in service might be 'immunized' against them by the sealing of the sites from which they begin.

And brittle materials like ceramics could at last be tamed. A ceramic turbine blade gradually loaded in hot methane–hydrogen would show its true strength at last. Deprived of the surface flaws from which to fail by brittle fracture, it could be loaded almost up to the point of plastic flow. Thus the splendid corrosion resistance and high temperature performance of ceramics will be made safely accessible to engineers. And the heat-stressed valves, blades, pistons and cams of modern high-power engines, so vulnerable even in metal, will be safe and durable at last. Even existing engines and turbines might be crack-proofed by pumping them up to speed with hot methane–hydrogen. David Jones

"There must be an easier way to synthesize DNA!"

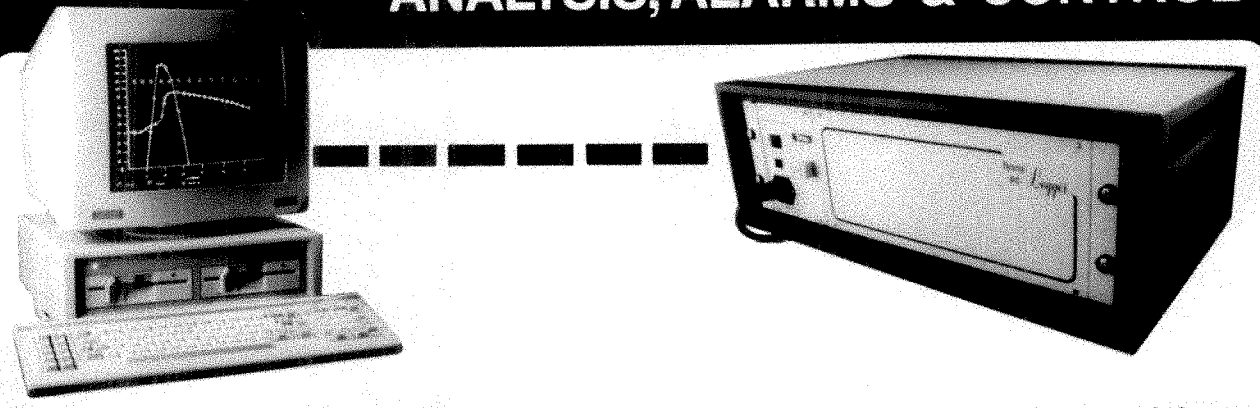
You said it yourself.

We call it Gene Assembler® Plus.

To begin with, Gene Assembler Plus is truly easy to get to know. All operations are controlled with the help of an IBM computer and incredibly easy software. Furthermore, with Gene Assembler Plus there's no need to prepare reagents or mix solvents. They're all prepacked and ready to use.

During operation, you can rest assured that success is ahead. A built-in monitor automatically registers the trityl concentration of each synthesis cycle. Coupling efficiency and yield are calculated for each cycle and results are displayed on the screen of your personal computer or printed out. If results differ from preset parameters, synthesis is automatically put on hold. This way you ensure a successful oligonucleotide synthesis without wasting expensive reagents or solvents.

Finally, we know that an easy-to-use synthesizer isn't the only key to successful DNA synthesis. That's why Pharmacia LKB is committed to providing you with all the help you may need . . . from synthesis to final purification.



Why don't you contact us today to find out more about how to make DNA synthesis easier.

flexsy PC Logger

BASED ON THE IBM PC FOR ACQUISITION, ARCHIVING & ANALYSIS, ALARMS & CONTROL

The intelligent and extremely versatile FLEXSY PC Logger will log and archive data, annunciate alarm conditions, and provide a notebook facility for each run. Data from the FLEXSY Logger are passed to an IBM or compatible PC for further processing by popular spreadsheet packages. FLEXSY's High Level Language also allows the user to extend the system to undertake conditional logging and control tasks to meet individual requirements.

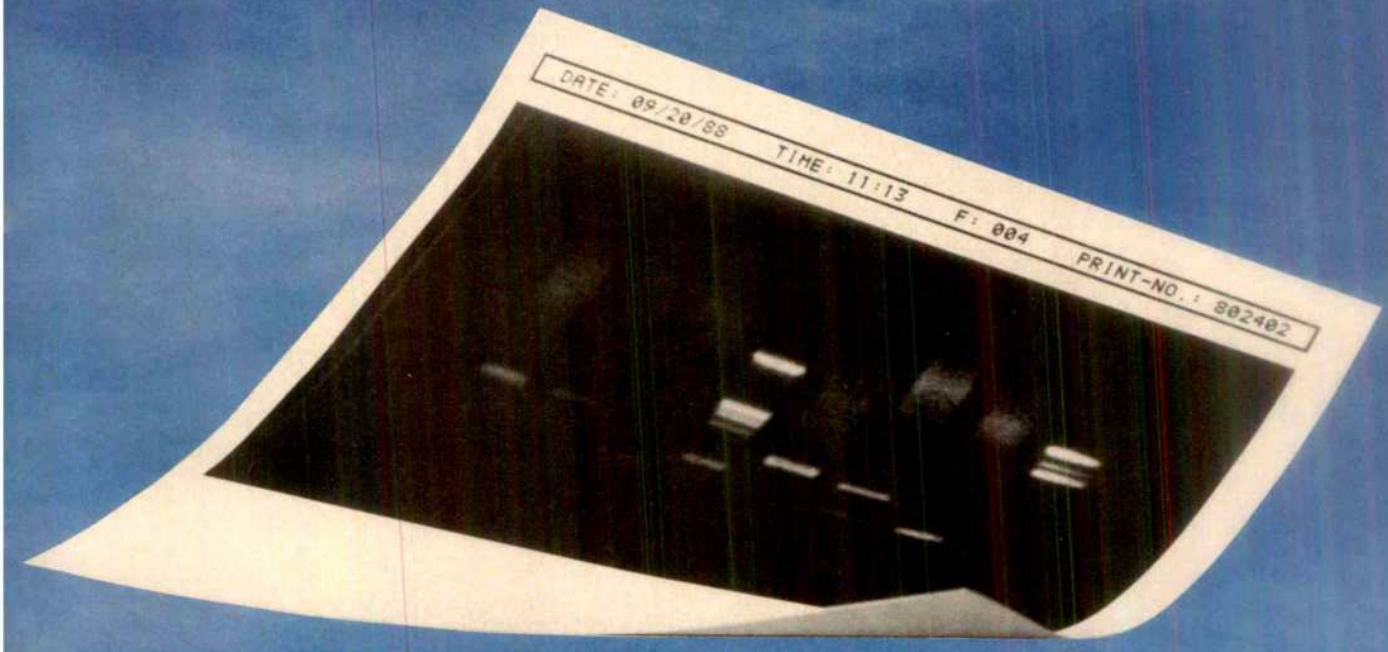
New products from FUNAKOSHI!

HIGH QUALITY RESEARCH REAGENTS

AVIDIN

High quality research grade AVIDIN is purified from chicken egg white. Bulk order available.

EGG YOLK LDL (Low density lipoprotein)



EGG YOLK LDL is prepared from specific pathogen free chicken egg yolk under sterile condition. Recent studies show that LDL have remarkably similar effect with fetal bovine serum.

Are your gel documentation costs soaring?

We bring them down to earth!

Electronic instant photographic camera
for quick and inexpensive documentation of:

- ○ DNA electrophoresis gels
- ○ Protein gels
- ○ TLC plates

The camera's thermoelectrically cooled CCD image sensor and specially developed interference filters yield excellent discernibility of low-light fluorescent patterns. The images are stored in a frame buffer and displayed on a television monitor. If desired, contrast amplification, edge enhancement and baseline subtraction may be performed on the stored images.

Hardcopies are printed out on high-resolution thermal paper within 20 seconds.

The images can be transmitted to a personal computer for further processing.

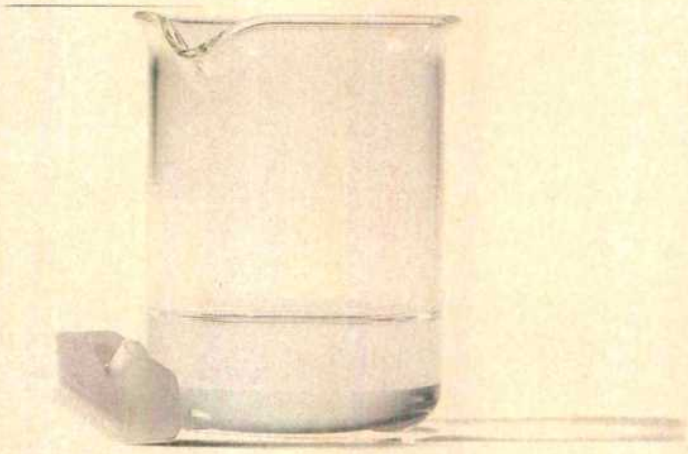
THE NEW ANOTOP™ PLUS
DISPOSABLE SYRINGE FILTER



Anotec Separations announce the latest addition to the ANOTOP range of disposable syringe filters – ANOTOP PLUS. A new prefilter and filter in one compact unit. Ideal for the preparation of difficult samples for analysis.

DOUBLY EFFICIENT

The NEW ANOTOP PLUS disposable syringe filter is ideal for cleaning up difficult samples which have heavy particulate loading, such as serum, food and beverage samples. The glass microfibre prefilter (which contains no binder) retains larger extraneous matter before the sample passes through the ANOPORE™ membrane below for precise filtration. Two filtration stages in one simple step. Removing the need for time consuming centrifugation or expensive sequential filtration stages. Yet all this is achieved without compromising on quality. The inorganic ANOPORE membrane contained in ANOTOP PLUS is still the most precise filter available today, offering well defined retention characteristics, low hold up volume and wide solvent compatibility. ANOTOP PLUS disposable syringe filters are available in 0.2, 0.02 and 0.1μm pore sizes (the 0.1μm is designed for Mycoplasma removal). If you are regularly faced with samples containing particulates then you need a syringe filter which is doubly efficient and singularly effective. Call now for your FREE catalogue.

SINGULARLY EFFECTIVE

Lethality of 'killer' bee stings

SIR—It has been predicted that Africanized honeybees (*Apis mellifera scutellata*) will displace European honeybees in warm climate areas of the United States after 1989 (ref. 1). In South and Central America, the highly developed colony defences of Africanized honeybees include a predilection for mass attack during which thousands of stings may be inflicted on one individual[2,3] causing life-threatening toxic reactions[4-9]. Although attacks of 300–500 stings have been survived without treatment[4], more than 500 stings are commonly fatal[8]. Strategies for minimizing the severity of reactions to Africanized bee sting attacks require information on the toxicity and quantity of the venom of Africanized honeybees. We report such data and conclude, by comparison with data from European bees, that the mortality associated with Africanized honeybee attacks is primarily the result only of the number of stings.

Worker (forager) honeybees (mainly *Apis mellifera ligustica*) were captured while returning to their hive in Tucson, Arizona. Attacking Africanized honeybees were captured from a colony in Guanacaste, Costa Rica[10] and identified by two independent morphometric determinations (H. Daly, University of California, Berkeley; S.W. Batra, Smithsonian Institution, Washington). Venom, free from contaminants, was obtained from the venom reservoirs by dissection as previously described[11], then lyophilized and stored at −20 °C.

Analysis of venom pooled from 1,000 bees of each type showed that European bees contained more venom (147 μg dry weight) than Africanized bees (94 μg), which were also smaller in size. The lethalities of the two venoms were calculated (as LD_{50})[12,13] from experiments in which Swiss mice and C3H/OuJ mice weighing 20–30 g were injected with venom in doses of 1,2,4 and 8 mg per kg, with eight animals per dose.

As shown in the table the lethality of the two venoms was not significantly different in Swiss mice challenged intravenously (i.v.) or intraperitoneally (i.p.), whereas Africanized bee venom was significantly less active than European bee venom in C3H/OuJ mice challenged intravenously.

Lethality of Africanized and European honeybee venoms in two strains of mice

	LD_{50} i.v. (mg per kg)	95% confidence interval	LD_{50} i.p. (mg per kg)	95% confidence interval
Swiss mice				
Africanized bee venom	2.8	2.0–4.1	2.8	2.0–4.1
European bee venom	2.8	2.0–4.1	3.8	2.2–6.4
C3H/OuJ mice				
Africanized bee venom	7.1*	5.7–8.8	ND	
European bee venom	4.6*	3.6–5.7	ND	

ND, not done.
* Significantly different, $P < 0.001$.

As the venoms from the two types of honeybee are of similar lethality, and as there is less venom in Africanized honeybees, the serious effects of multiple stings from Africanized honeybees seem mainly to be attributed to the multiplicity of stings. Perhaps use of the popular term 'killer bee' to describe the Africanized bee is inappropriate.

Sexual advantage

SIR—Kelley *et al.*[1] report a 1.43-fold advantage for sexual over asexual reproduction in sweet vernal grass and thus seem to answer the question of "the ubiquity of sex." However, we find several problems in their methodology and analysis of the data.

First, in an attempt to simulate the natural dispersal pattern of the offspring, Kelley *et al.* planted sexual and asexual progeny conforming to the seed dispersal pattern around the parent. This is erroneous for two reasons. (1) Asexual progeny (tillers) are generally conjoint with the parents and do not disperse as widely as seeds. Planting asexual tillers in a pattern conforming to that of seed dispersal will grossly overestimate their fitness as it relieves them from competition for resources from the parent plant and also provides liberal space for the daughter tillers to sprout. (2) The natural pattern of distribution of the seedlings surviving to the age at which the authors transplanted the 'test' seedlings would be different from that of seed dispersal around the parent. Although the number of progeny is calculated, this is not used to arrive at the pattern of seedling distribution. Even if it had been, the failure to incorporate data on density-dependent germination and seedling survivorship at various distances from the parent would weaken the analysis. We believe that the planting pattern followed is very unnatural, and that the fitness estimates obtained are therefore incorrect.

Second, the relative advantages of sexual and asexual reproduction was compared using the number of inflorescences produced by the respective ramets. It denies logic to suggest that asexually reproducing organisms gain fitness through organs involved in sexual reproduction such as inflorescenes and spikelets. A valid method could be to compare the number of tillers produced by asexually reproducing ramets with that of equal-aged seedlings produced from the total spikelets of the sexually reproducing ramets. Clones of purely sexual and asexual types would be needed for such a comparison, but unfortunately they are not found in sweet vernal grass.

Third, the authors attempt to test "spatially varying environment as a selective force favouring sex" by comparing the relative fitness of the sexual over asexual reproduction for a 2-m distance from the parent. We do not think that the 2-m range is sufficient to represent a spatially varying environment; nor are we provided with any index of environmental variation within this 2-m radius around the parent plant.

Finally, the degrees of freedom for parents in Table 1 of ref. 1 should be 24 rather than 25.

R. UMA SHAANKER
K.N. GANESHAIAH
Departments of Crop Physiology and Agricultural Botany,
University of Agricultural Sciences GKVK Campus,
Bangalore 560 065, India

KELLEY *ET AL.* REPLY— Shaanker and Ganeshaiah seem to have misunderstood the purpose of our experiment. We intended to test the short-term advantage of sexual versus asexual reproduction, and not the advantage of seed versus vegetative propagation. Hence, we were interested in measuring the short-term selective force which would act against a mutant coverting sexual to asexual seed production (if and when it arose). Both

sexual and asexual progeny were thus planted in the locations to which seeds would naturally have been dispersed, because our hypothetical mutant presumably would not alter both the mode of reproduction and the mode of dispersal. The transplanted tillers were similar both in size and in age to seedlings which had germinated the previous fall in the field. We acknowledge that our simulation was a first-order approximation of the natural progeny dispersal pattern in the field, and that it did not incorporate data on density-dependent germination and seedling survivorship. As far as we are aware, few data on this point exist. Nevertheless, our previous experiments have shown remarkably little response of adult tillers and seedlings of *Anthoxanthum* to density variation in the field[2,3]. Further, the relative advantage of sexual progeny in *Anthoxanthum* is not strongly affected by changes in planting density[2]. We suspect, therefore, that our simulation of progeny dispersal is not particularly unnatural.

Shaankar and Ganeshaiah again seem to confuse asexual reproduction with vegetative reproduction when they argue that inflorescence number is an inappropriate measure of fitness. Hypothetically, asexual progeny could produce apomictic seeds, and hence gain fitness through inflorescences and spikelets. (Using the number of vegetative tillers as an estimate of fitness, our data still show a significant advantage for sexual progeny. The relative fitness of sex is 3.34 ± 0.71 when calculated using the number of vegetative tillers at the end of the second year as an estimate of fitness.)

Our experiment was not designed to test the spatially varying environment hypothesis, and difficulties in testing this hypothesis arise because distance from parent is confounded with progeny density. Nevertheless, the choice of 2 m as the maximal distance for planting was entirely appropriate in *Anthoxanthum*, as 99 per cent of all seeds is dispersed within 2.0 m. Hence, although experiments we have done do show a greater advantage for sexual progeny at greater distances (10 m) from the parent[4], such considerations are not relevant to explaining how a twofold advantage for sexual reproduction could arise, unless rare long-distance dispersal yields a considerable advantage for the sexual progeny, such as in a colonization event. The plant community within which the present experiments were conducted is relatively stable[5], and hence it is unlikely a significant short-term advantage for sex arises in this *Anthoxanthum* population from long-distance dispersal.

Shaankar and Ganeshaiah are correct to note that the degrees of freedom for parents, distance × parent, and parent × sex should be 24, not 25. However, the effect of this error was to deflate the *F*-values. The correct *F*-values are of higher significance, and our conclusions are unaffected. In summary, we believe our results are sound and provide clear evidence for a short-term (within a generation) advantage for sexually reproducing females.

Thoroughbred breeding

SIR—Gaffney and Cunningham[1] and Hill[2] have addressed a biological dilemma with important consequences by illustrating that although TIMEFORM ratings for thoroughbred horses are increasing by about 1 per cent per year, the winning times for the English classic races have not changed appreciably since 1930. I propose that there is insufficient variation in speed realistically to expect significant reductions in winning times, and improvement in TIMEFORM ratings may be due to components of racing ability other than speed.

The genetic principle under investigation is that of a correlated response in winning time to selection based on TIMEFORM ratings. The expected correlated response per generation (CR) can be calculated from the formula[3] $CR_S = ih_S h_T r_G \sigma_S$, where S represents speed, T the TIMEFORM rating, i the intensity of selection, h the correlation between phenotype and genotype, σ the phenotypic standard deviation, and r_G the genetic correlation between speed and TIMEFORM rating.

One proposition to explain the contradiction is that the standard deviation for speed is very small. Data to compute this statistic directly are unavailable and so σ_S is estimated here from observations of trial races of 1,200 metres (six furlongs). A high proportion of horses trained for racing compete in such trials in which the distance between first and last seldom exceeds 70 metres. A typical winning time for 1,200-metre races is 72 seconds [4], and therefore a distance range of 70 metres represents a time range of about 4 seconds. Assuming that this range spans 95 per cent or 4 standard deviations of the population the standard deviation for time to run 1,200 metres is 1 second. From Gaffney and Cunningham $(i_m + i_t)/(L_m + L_t) = 0.132$ and $h_T = 0.6$. Substituting these values in Falconer's formula: $CR_S = 0.132 \times 0.6 \times 1 \times h_S r_G = 0.079\, h_S r_G$ seconds per year and taking 0.6 and 0.8 as arbitrary values for h_S and r_G respectively, $CR_S = 0.04$ seconds per year or 2 seconds per half century. This represents a response in speed of 2.7 per cent which is considerably lower than the 5 per cent predicted by Hill, but is still greater than the improvement indicated by Gaffney and Cunningham. But the predicted response will approach zero if the values of h_S and or r_G are lower than assumed above.

Why, then, have TIMEFORM ratings improved by 1 per cent per year whilst winning times have not changed significantly? A possible explanation is that breeders have difficulty in ranking animals across years. In this instance the problem may be compounded by TIMEFORM rating being subjectively assessed and influenced principally by a horse's ability to win races. Although such ratings may accurately rank animals within age group, their reliability as a measurement from which to estimate rates of genetic change should be addressed.

On the other hand, the improvement in TIMEFORM ratings may be a true reflection of genetic progress for ability of horses to win races. This 'ability to win' encompasses many traits such as strength, temperament, speed and desire to win. The fact that winning times are not changing may simply mean that speed has become a relatively unimportant component of 'ability to win' in thoroughbred horses during the past 50 years.

PHILIP R. BEATSON
Lincoln College, University College of Agriculture, Canterbury, New Zealand

CUNNINGHAM REPLIES—Eckhardt *et al.*[5] in their comment on our paper[1] suggest that the record times for the Derby in 1987 and 1988 provide evidence that racehorses are becoming faster. These two times do not invalidate our general point that winning times have been nearly static for more than 50 years. The main conclusion of our study[1] was in fact that genetic improvement in racing ability of the thoroughbred population as a whole has been very close to what selection theory predicts. We made the point that winning times of the best horses in the most prestigious races are not an accurate measure of genetic change in the population as a whole.

The speculations of Eckhardt *et al.* about the reasons for slow genetic improvement in thoroughbreds, although interesting, are not necessary, and are also debatable. Eckhardt *et al.* suggest that racing ability calls on such a wide range of structural and physiological factors, some of which are antagonistic to each other, so that improvement in net effect is more difficult than it is for economic traits in other domestic animals. A high-perform-

ing dairy cow, for example, secreting 3 kg of milk solids per day, makes comparably wide demands on her physiology.

Eckhardt *et al.* argue that genetic variation for running ability in horses may have been depleted by a long evolutionary history during which this was an important survival trait. Again, it could be argued that the evolutionary imperative was to outdistance predators, whereas the modern racing goal is to outdistance other horses. The first may have an intermediate optimum; the latter clearly is unbounded. Our estimate of the heritability of TIMEFORM rating, about 35 per cent, is similar to other estimates for different measures of racing ability, and all indicate substantial additive genetic variance.

How can the different question of static (or nearly static) winning times in classic races be resolved? One answer may be that tracks are now watered in dry years. Another is discussed above by Beatson, who suggests that selection on a subjective criterion like TIMEFORM rating produces a negligible correlated response in racing speed because of the very low variance in the latter trait. The low estimate of variability of racing time which he provides (CV=1.5 per cent) is supported by a similar value (CV=1.3 per cent) obtained by analysing many time records in greyhounds[6].

Another reason could be that winners in classic races are close to some physiological limit. Lactic-acid accumulation in blood rapidly reaches critical levels in horses undergoing continuous exertion[7]. This would impose limits in longer races but be less restrictive in shorter ones. There is a suggestion of a more pronounced plateau in performance in winning times in the St Leger (1¾ miles), than in the Oaks, Derby and Belmont (1½ miles), with even less evidence of a plateau in the Kentucky Derby (1¼ miles) and the Preakness (1 3/16 miles).

HLA and insulin-dependent diabetes mellitus

SIR—The contribution of the polymorphic residue at position 57 of the HLA-DQβ chain to autoimmune diabetes (insulin-dependent diabetes mellitus or IDDM) has been discussed recently[1–5]. Genetic susceptibility to IDDM is positively correlated with a neutral residue (Ala, Val, Ser) and negatively correlated with an Asp at this position. Position 57 is also revealed as a critical residue in the analysis of *Pemphigus vulgaris*[6] but susceptibility to *P. vulgaris* seems to be a property of the allelic β-chain structure rather than just residue 57. Similarly, for IDDM susceptibility, there are several haplotypes with a neutral residue at 57 that do not confer high susceptibility (for example, DR7) and some with Asp 57 that seem to be disease-associated (for example, DR4 and DRw9 in the Japanese). Another challenge for the simple residue-57 model is how to account for the increased risk of DR3/4 individuals relative to DR3/3 or DR4/4 individuals as they are all non-Asp 57 homozygotes. These observations are most simply explained by assuming that other HLA class II sequences can also confer susceptibility to IDDM. The DRβI allele, for example, seems to contribute to the DR4 association with IDDM[7,8]. In general, it is specific combinations of class II alleles (haplotypes and genotypes) that are most highly associated with disease.

Notwithstanding these and other exceptions[9], the data implicating residue 57 as critical in disease susceptibility are striking: this intriguing correlation demands an explanation. One possibility is that the region around position 57 of the DQβ chain encoded by a susceptible allele (for example DQβ3.2) presents an autoantigen to the T cell or determines the expression of a particular T-cell receptor during thymic maturation[1,4]. The notion, however, that all allelic DQβ chains that contain Asp 57 (or non-Asp 57) bind a common islet cell autoantigenic epitope or influence the T-cell receptor repertoire in a similar way seems unlikely given the diversity of Asp 57 (or non-Asp 57) alleles (Table 1). An alternative interpretation is that the residue at position 57 may simply influence the overall conformation of the β-chain and not necessarily interact directly with a putative autoantigen. The functional significance of position 57 is suggested by the conservation of this charge polymorphism in all human class II β-chains (DQβ, DRβI, DRβIII, and DPβ). In fact, position 57 polymorphism at these other β-chain loci may also be relevant to disease susceptibility[4,5]. Moreover, the same polymorphic residues are found at position 57 in chimpanzee, gorilla, baboon, rhesus and cebus β-chain alleles (Table 2; Gyllensten *et al.* unpublished observations). The evolutionary maintenance over 10–20 million years of a balanced polymorphism between Asp 57 and Val, Ala or Ser at this position in all class II β-chains examined so far suggests that β-chains containing Asp 57 and those with Ala, Val, or Ser at position 57 may be structurally and functionally different. Perhaps, selection for the presence of both types maintains this polymorphism[10]. Whatever the functional significance of residue 57 polymorphism, the general correlation observed between disease susceptibility and the nature of residue 57 may ultimately reveal more about the structure of class II β-chains than about the specific response to a putative diabetes autoantigen.

Single-strand RNA

SIR—In their News and Views article, Lamb and Dreyfuss[1] state "All RNA viruses have to go through a ds RNA intermediate in their life cycle". If "ds RNA" designates double-helical RNA, this statement is incorrect, for the replication intermediate of RNA phage Qβ is a single-stranded minus strand, and not double-stranded RNA[2]. The same is thought to be true of many of the animal positive-strand RNA viruses, including picornaviruses, togaviruses and coronaviruses[3], although

the data are not clear-cut. There is no evidence that double-stranded RNA is an intermediate in the case of transcription and replication of negative-strand viruses (D. Kolakofsky, personal communication); rather, RNA is complexed to nucleocapsid protein, which probably prevents formation of double-stranded RNA.

Double-stranded RNA is nevertheless formed as a dead-end side product of Qβ RNA replication, presumably when there is a failure of the mechanism that separates or keeps apart plus and minus strands during synthesis[2]. In the case of eukaryotic minus-strand viruses it may be a similar rare event that gives rise to a double-stranded RNA that can be taken apart by the modifying/unwinding enzyme of Bass and Weintraub[4] and give rise to hypermutated RNA[5].

Were double-stranded RNA an obligatory intermediate of eukaryotic viral RNA replication, one would expect hypermutational events to be frequent, rather than very rare[5]. Maybe it is the avoidance of double-stranded RNA intermediates that enables RNA viruses to circumvent lethal hypermutation in eukaryotic cells.

Human T-cell receptor expression

SIR—Janeway, in his recent News and Views article[1], stated that intestinal epithelial lymphocytes "in both chickens and man are predominantly CD8$^+$ T cells with γ/δ receptors". In our immunohistochemical studies of human intraepithelial lymphocytes, we also find that most intraepithelial lymphocytes express CD8, although approximately 20% of intraepithelial lymphocytes express neither CD4 nor CD8.

Using an antibody against the δ-chain of the T-cell receptor (δTCS1, T Cell Sciences Inc., Cambridge, Massachusetts) however, we have failed to demonstrate a predominance of δ-chain-positive lymphocytes in normal gut epithelium. We are unable to detect any δ-chain-positive cells in human fetal ileum at 20 weeks' gestation, when intraepithelial lymphocytes expressing CD3 are present[2]. We find that only 2 per cent of intraepithelial lymphocytes in normal adult jejunum, increasing to approximately 33 per cent in jejunum from children with newly diagnosed coeliac disease, express this form of the T-cell receptor. These findings suggest that accumulation of intraepithelial lymphocytes expressing the δ-chain of the T-cell receptor is antigen driven, but that in normal, immunologically stable intestine, the proportion expressing the γ/δ heterodimer is small.

JO SPENCER
PETER G ISAACSON

University Street,
London WC1E 6JJ, UK

JANEWAY REPLIES—Spencer and Isaacson's statement that human intestinal epithelial lymphocytes may not be enriched in γ/δ T cells is further evidence of the need to correlate anatomy to structure and function. My statement regarding the presence of such cells in man[1] was based on results using the same antibody carried out by Bucy in Cooper's laboratory, and reported at the last FASEB conference in Las Vegas, Nevada.

I have since learned that another antibody of similar specificity also fails to reveal dominance of such T cells in gut epithelium in man (Groh *et al.*, personal communication). However, we now have evidence that intestinal epithelial lymphocytes of mice are using a V_γ:V_δ different from that found in any other tissue, including skin. Thus, one must be sure that the reagent used will react with all T cells bearing γ/δ receptors before such conclusions are validated. It is also possible that the results in the mouse reflect the early age at which such cells are collected. The γ/δ receptors in the gut and skin of the mouse are of a form found only very early in ontogeny in the thymus, and seem to rapidly seed these unique peripheral sites. The decline in such cells cited by Spencer and Isaacson may reflect this ontogenetic history.

However, the data of Spencer and Isaacson, and of Groh *et al.*, could reflect a major interspecies difference. If this last hypothesis is correct, would it be too far-fetched to speculate that the reason humans have spontaneous carcinomas, whereas mice seem to have sarcomas and lymphomas as their main tumour types, is that humans have a defect in the disposition of γ/δ T cells in their epithelia, thus allowing transformed epithelial cells to arise and proliferate sufficiently to invade and cause disease?

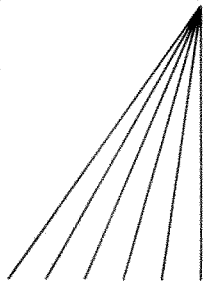
Taxonomic stability

SIR—Crisp and Fogg[1] correctly point out that changes in names for taxonomic reasons, which arise from differing opinions on classifications or new data, are tiresome. Nevertheless, when changes arise from a more thorough understanding of evolutionary relationships they must be accepted as part of the development of science, as stressed by Newman[2].

The current International Union of Biological Sciences *Lists of Names in Current Use*[3] initiative aims to limit changes arising from the application of International Codes[4,5], rather than as a result of new scientific research. The most effective tool for restricting irresponsible taxonomic changes is peer pressure. Progress in that direction is starting to be made in the Ascomycotina, the largest class of fungi (6,100 generic names; 29,000 species). An interactive eclectic approach to the production of a generally accepted system for ranks from genus to order was initiated in 1982, based on a twice-yearly publication of this institute and the University of Umeå, *Systema Ascomycetum*, which reports changes in classification and reactions to them. Depending on world-wide peer reaction, changes are incorporated into an annually revised "Outline of the ascomycetes"[6], providing recommended dispositions of generic and higher ranks. Users have an annually updated listing to which they can refer. Parallel publications could clearly be initiated for other groups of organisms, were the necessary resources made available.

At the species level, the International Commission on the Taxonomy of Fungi (ICTF) produces a series "Name changes in fungi of microbiological, industrial and medical importance"[7]. The reasons for changes proposed in the naming of these fungi are reviewed by an international panel of 11 mycologists, and their views are embodied in this series. Again, this could be adopted on a wider front.



International peer reactions are the most likely prospect for restricting unwelcome changes of the type Crisp and Fogg abhore. In the longer term, improvement in the standards of taxonomic practice such as the ICTF "Code of Practice for Systematic Mycologists"[8,9], are required.

Making it big in the molecular world.

We're one of the world leaders in the synthesis of biomedical research chemicals. We make everything from oligosaccharides & mutagens to glycosidase inhibitors and diagnostics. Both cold and radiolabelled. For everyone from research end users to chemical companies. And what we aren't making we'd be pleased to create on request. We have a reputation for purity and consistency that is second to none. And an equal commitment to new product development. Once you deal with us you'll wonder how you managed without us.

A NEW REMOVAL AGENT FOR NUCLEIC ACID AND ENDOTOXIN

A low molecular chitosan derivative which was modified from natural chitin has developed for elimination of nucleic acid and endotoxin effectively.

CHARACTERISTICS AND APPLICATIONS

* High solubility. (20 times more than ordinary chitosan.)
* Low intrinsic viscosity. (< 0.68 dl/g)
* High removal efficiency. (more than 99%)
* Suitable for large-scale purification in pharmaceutical production.

Perspectives on Biogeochemistry

1989. 296 figures. Approx. 450 pages. Soft cover DM 98,-.
ISBN 3-540-50191-6

Contents: The Cosmos at Large: Matter and Forces. Instant of Creation. Incidents During Expansion. Our Solar System. - Down to Earth: Fire. Coordination Principles. The Earth from Within. From Land to Sea. - Life-Supporting System: Air. Water. Life. Biogeochemical Evolution. - References. - Subject Index.

Perspectives on Biogeochemistry is an account of the origin of forces and matter at the dawn of time, and the way they evolved to planet Earth of today.
Several fields of natural sciences are consulted to present a coherent view on the cycling of terrestrial elements and molecules, both organic and inorganic, in the course of time. Critical data are drawn together from astronomy, physics, chemistry, biology, and geology in order to provide some understanding of the complexity of the system Earth.
In this book, E. T. Degens abstracts his knowledge of bio-geochemical interactions aquired in more than thirty years of research and teaching.
Students and researchers will profit by the very thorough and personal view of this pressing topic.

sb. 8820/4/2h

☐ **ONCOGENE**
AN INTERNATIONAL JOURNAL

Editors: Graham Currie and John Jenkins, Marie Curie Research Institute, Oxted, Surrey, UK

Prem Reddy, The Wistar Institute, Philadelphia, USA

This new journal includes full and detailed papers as well as short communications relevant to all aspects of oncogene research, including the following topics: cellular oncogenes and their mechanisms of activation, structure and functional aspects of their encoded proteins, oncogenes in RNA and DNA tumour viruses, presence of oncogenes in human tumours, relevance and biology, cell cycle control, immortalization, cellular senescence, regulatory genes and "anti-oncogenes", growth factors and receptors.

The international editorial board draws upon a wide range of expertise from the UK, USA, USSR, Federal Republic of Germany, France, Canada and Israel.

☐ **BONE MARROW TRANSPLANTATION**

Editors: John Goldman, MRC Leukaemia Unit, Royal Postgraduate Medical School, Hammersmith Hospital, London, UK

Robert Peter Gale, Division of Hematology and Oncology, UCLA School of Medicine, Los Angeles, USA

A new journal which publishes clinical results in man and experimental results with animals. It covers allografting and autografting, HLA and other methods of selecting donors, graft-versus-host diseases and methods to prevent and treat it, and much more.

☐ **ANTI-CANCER DRUG DESIGN**

Editors: Stephen Neidle, Cancer Research Campaign Biomolecular Structure Unit, Cancer Research Institute, Sutton, Surrey, UK

Stan T. Crooke, Smith Kline and French Laboratories, Philadelphia, USA

Shigeru Tsukagoshi, Cancer Chemotherapy Centre, Japanese Foundation for Cancer Research, Tokyo, Japan.

This journal publishes original research papers, reflecting the increasing importance of the tools of structural and molecular biology as well as more classical methodologies in the development of novel anti-cancer agents.

Breaking resistance

ndrew Holmes-Siedle

uperconductors: Conquering Technology's New Frontier. By Randy Simon and ndrew Smith. *Plenum: 1988. Pp.326. $28.74, £16.*

o physicists and engineers, the lure of uperconductivity lay perhaps in its esemblance to magic. They had been ught that the consequence of passing lectrons through wires was heating. lthough true in the everyday world, ere was nevertheless a wonderland here the usual laws according to Ohm nd Ampère did not operate. It was a inter wonderland, a little chamber overed with icicles. The magic effect only ok place near absolute zero, requiring n expensive coolant, liquid helium. The irst attempt to harness the magic failed; a eneration of engineers who hoped to use uperconductivity in computers had their reams frustrated because of the price of ooling. Then, in 1986, materials scientists nade the first high-temperature super-onducting ceramic systems.

This breakthrough has caused an nusual flutter in the wider world. In part his is because some people believe that uperconductor magic has broken out of airyland and is about to transform our orld. There is thus a place for a book hich attempts to tell people how super-onductivity works and how it might, ndeed, change the world. Randy Simon nd Andrew Smith tackle this task in traightforward fashion. Their writing is nformal but makes no concessions when a difficult point is to be made. If readers have to stretch their imaginations a bit, the authors give them due warning and provide the tools of analogy to help them along. One reason for this confident style is that both authors are physicists who themselves work on high-temperature superconductors for an aerospace firm. They are in the forefront of their field, and have probably had to explain the same points to their managers a hundred times. At the same time, the writing is highly polished. This is no journalistic paste job.

Twelve chapters take the reader logically through the history, physics and engineering of superconductors, and describe both the old and new versions. The old, low-temperature (LT) superconductors are based on alloys of niobium, tin and lead, and are cooled by liquid helium or neon. The new, high-temperature (HT) varieties are based on cuprate ceramic compounds, and operate at temperatures near that of boiling nitrogen (high temperature in this context). These are dealt with in the final four chapters of the book, which discuss the excitement of the advances that have been made in the past three years. Chapter 13 gives a historical account of the initial discovery in 1986; and Chapter 14 describes the most popular research material, yttrium–barium–copper-oxide.

In the last two chapters the authors consider the future. Here, however, they have not done a real analysis of the uses and economics of the new materials, so their predictions are qualitative. But their views are logical — and agree with those of many reasonable people.

In the 1970s, the goal for the superconducting computer was to make a device, cooled by helium, that would fit inside a teacup and could reel off the names of every person in the world in one second. The efforts failed (the computer equipment looked like a kitchen stove), primarily because of the poor thermal properties of helium. Such computers had some highly specialized uses, including many military applications, but by the early 1980s research in the United States was faltering. The authors do not clearly explain why this was so, but they do spell out with enthusiasm the case that was being made for the continuance of LT research. This case was based on the advantages of the LT superconductor — speed of switching, absence of electrical noise and uniquely precise action in sensor devices.

The authors are confident that the discovery of HT effects will reverse the trend and revive research into LT superconductors. But they fail to mention a strong argument for continuing LT work, namely that the experience of workers in that technology might be harnessed to explore the possibilities of the HT effect. At the very least, LT research should continue while the basic physics and materials science of the new systems are studied.

We are by no means sure that the HT effect will do the things we want. Higher temperature is bound to erode one of the three advantages mentioned earlier, low-noise operation. Furthermore, the lattice structure of the new materials impairs electronic functions and may present insuperable barriers to widespread commercial success. We can only hope that the speed and precision of many classical superconducting effects are not affected too badly by this materials problem. Nevertheless, it will be surprising if the HT effects do not find some startling, novel uses.

Without trying to be prophetic, the authors set the scene for the growth of HT superconductors into a high-technology industry. Their well-balanced account of a complex technical challenge is likely to help laymen appreciate what is going on; many scientists who need a quick review of the subject will also want to read the book. If zero-resistance materials and new quantum-effect devices are going to come out of the winter wonderland and into the real world, then we all need to know about them. □

Andrew Holmes-Siedle is owner of REM Instruments, 64A Acre End Street, Eynsham, Oxford OX8 1PD, UK, and a consultant to the Fulmer Research Laboratories, Stoke Poges, near Slough, UK.

Question time for psychologists

Stuart Sutherland

Stevens' Handbook of Experimental Psychology, 2nd edn. Vol. 1 **Perception and Motivation;** Vol. 2 **Learning and Cognition.** Edited by Richard C. Atkinson, Richard J. Herrnstein, Gardner Lindzey and R. Duncan Luce. *Wiley: 1988. Vol. 1 pp. 905, $85, £77.50. Vol. 2 pp. 1,027. $95, £85. Two-volume set $180, £160.*

IN PSYCHOLOGY, old problems never die, they only fade away. On the other hand, new problems emerge at a remarkable rate. So it is instructive to compare the second edition of *Stevens' Handbook of Experimental Psychology* with the first, which was written nearly 30 years earlier.

The 'phi phenomenon', the illusion of movement occurring without anything being seen to move, received a great deal of attention in the first edition, but is not so much as mentioned in the second. As to the new and largely unanswered problems, here are two. First, when an ambiguous word (such as 'bank') is encountered, do people unconsciously access both meanings of it or are they directly guided by the context to the correct interpretation? Second, it has recently been discovered that people are very bad at probabilistic reasoning. For example, they fail to obey Bayes' law since they attach far too little weight to prior probabilities. Why this should be so remains unclear, although it may in part be due to a tendency to access the most salient material. For example, most people wrongly believe there are more words beginning with 'r' than words having 'r' as a second letter, because it is easier to recover from memory words starting with 'r' than words having 'r' in any other position.

Stereopsis

The failure to solve old problems and the constant emergence of new ones suggests that psychology makes little progress, but this is not entirely true. For example, in stereopsis the task of deciding which points on each eye are being stimulated by the same points in space (the correspondence problem) is an ancient one, but there are now plausible algorithms that can execute it. These receive only a cursory mention in the chapter on visual perception: unfortunately some psychologists still regard workers in artificial intelligence as rivals rather than allies.

Although the most secure advances may have occurred in vision and hearing, many discoveries have been made and a few theories put forward in other areas that are unlikely to be completely swept away. The notion that a concept may be based on a prototypical instance to which other instances bear a family resemblance goes back to Wittgenstein, but more recently it has been experimentally shown to apply to at least some concepts. As Eliot Hearst shows in an exceptionally clear and thorough chapter, even animal learning, currently a neglected field, has taken a dramatic step forward. It has been found that the formation of an association between two stimuli (for example, the conditioned and unconditioned stimuli) depends not merely on how frequently one is followed by the other, but on the second stimulus occurring more frequently after the first than in its absence. From a functional standpoint, this makes good sense. Animals, and people, need to learn about stimuli that predict an event better than other stimuli, not merely about random connections between the members of a pair of stimuli.

In psychology, the discovery of new phenomena has usually been determined by changes in the *Zeitgeist*, which in turn have often been influenced by the importation of new ways of thought from other disciplines. Elderly experimental psychologists, such as myself, have seen the subject successively transformed by cybernetics, information theory, Chomsky's generative grammars and artificial intelligence. All four movements suggest that it may be possible to describe and explain complex information-processing with rigour; hence the swing of experimental psychology away from behaviourism to a cognitive approach. The word 'cognitive' has been broadly interpreted because it includes not merely conscious mental processes but the unconscious ones that underlie them. Oddly enough it is the unconscious processes on which most progress has been made. Whereas there are plausible, but unfinished, theories about object recognition (a topic completely omitted from both editions), pitch perception, auditory localization and speech perception, theorizing on the higher realms of cognition remains vague. We have very little idea how memories are accessed and *a fortiori* how they are organized. And although it seems certain that reasoning proceeds by manipulating the semantic content of mental models rather than by the formal application of a logical calculus, we can hardly begin to specify what these mental models are like.

The influence of the information-processing sciences on psychology is new, but that of neurophysiology and related disciplines goes back many years. Today, hacking out pieces of animals' brains more or less at random has been largely supplanted by the study of neurological patients whose brains have suffered random damage through strokes, tumours or accidents. Such research is a secure and easy route to a PhD or an enlarged list of papers. But although it may provide information on where in the brain a given function is localized, it rarely yields any evidence that is relevant to the really important question of the nature of the mechanisms that execute it. Again, although Bartley Hoebel provides a detailed and scholarly account of recent work on neurotransmitters, the knowledge that they are heavily implicated in a variety of motivational systems, or even the more specific knowledge that the catecholamines play a role in the 'pleasure centres', does not appear to have advanced our knowledge of the mechanisms underlying reinforcement — let alone pleasure.

Experiments

The *Handbook* is not for beginners. It is written with the accuracy one might expect from the 40 or so distinguished contributors, but many of the chapters will be opaque to psychologists who do not themselves work in the field under review. There is little attempt to place a topic in perspective or to state clearly which problems (if any) have been solved and which remain unsolved, or even to decide what the important issues are. Instead, the reader is too often presented with a mass of experiments unadulterated by theory. Experiments are described that were intended to support theories long since shown to be fallacious — for example, those of A.M. Collins and M.R. Quillian that purported to show that the attributes of classes are held hierarchically, so that in memory yellow would be attached to canary, but flying would be attached to a higher node (bird). With several interesting exceptions, such as the chapter by S. Glucksberg and G.A. Miller on the psychology of language, most of the contributors seem to believe that if an experiment has been conducted it must be worth reporting.

Of course, experimental psychology has always lived up to its name and has tended to place more weight on experiments than on theory. The subject is, however, at present undergoing a fifth revolution, namely the development of simulated neural nets consisting of units randomly connected together, in which learning is represented by changes in the connectivity. Such nets have been found to be capable of performing surprisingly complex tasks and have been hailed as the theoretician's paradise. Unfortunately they are unlikely to introduce theoretical rigour into psychology if only because, for the most part, nobody understands how they work. □

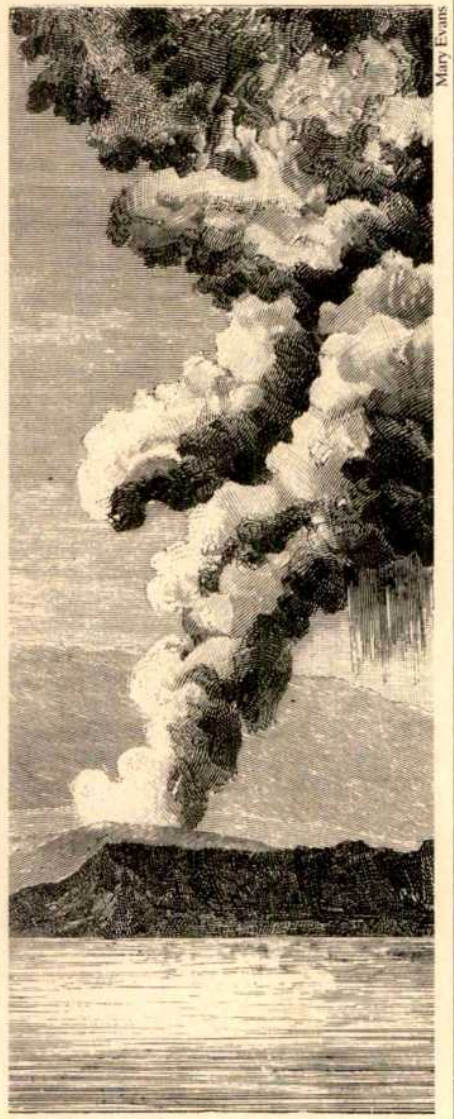
The view from Leningrad

A. Barrie Pittock

Climate Shocks: Natural and Anthropogenic. By K. Ya. Kondratyev. *Wiley: 1988. Pp.296. $54.95, £50.*

IN THE foreword to *Climate Shocks*, Will Kellogg describes the book as "an extraordinary *tour de force*" and "a scholarly achievement that is unmatched, to my knowledge". Unfortunately, I cannot agree. The book is certainly interesting to a relative insider, and it raises a number of points which deserve further attention. But, despite his eminence, Kondratyev puts forward a rather idiosyncratic view which will leave many readers bewildered rather than enlightened.



After a brief introduction to physical climatology, there follows an account of the greenhouse effect, and longer chapters on the climatic consequences of volcanic eruptions and on those that might result from a nuclear war. The latter contains a large section on the possible effects of the Tunguska meteor fall in 1908. A final chapter purports to present recent results and conclusions, but in fact largely summarizes the unrefereed papers that were presented at one particular conference held in 1985.

Throughout the book Kondratyev tends to give rather uncritical, detailed and technical summaries of selected papers, many of which are out of date, there being frequent confusion between the views contained in the original papers and those which the authors now hold. The result is a perplexing array of often contradictory statements, with too little attempt to mould the material into a rounded overview.

A central theme is the author's conviction that oxides of nitrogen, supposedly produced in large quantities by the atmospheric nuclear bomb tests of the 1950s and 1960s, caused a significant surface cooling in the Northern Hemisphere (an 'anti-greenhouse effect'), and that they would have caused a decrease in stratospheric ozone had it not been for a simultaneous injection of water vapour into the stratosphere. Kondratyev invokes the mechanism to reconcile the observed average surface temperature trends in the Northern Hemisphere in the 1930s through to the 1970s with the expected warming due to the greenhouse effect. But this requires him to add a contribution from industrial NO_x production before the bomb tests; as this input is tropospheric, the theory hardly stands up to close examination.

The NO_x theory is based on a controversial paper by Hampson (*Nature*, **250**, 189; 1974) and a time series of NO_2 concentrations derived by Kondratyev and coworkers by working back from the time series of ozone amounts. On p.177 he blames other people's failure to agree with his interpretation of the ozone record following the nuclear tests on rejection of the Soviet data obtained with the M–83 ozonometer; yet on p.192 he concedes that turbidity caused errors in the M–83 measurements.

Nitrogen oxides are also invoked to help 'explain' phenomena associated with the Tunguska meteorite event. Much space is devoted to explanations of the time series of atmospheric optical thickness over Mt Wilson, which shows peaks

Mary Evans

Perturbation for climate (and much else besides) — Krakatoa blows its top in 1883.

on 4 June 1908 and some 60 days later. The Tunguska event occurred on 30 June, so Kondratyev postulates another "pre-Tunguska stone meteorite" which supposedly disintegrated over Tibet on 4 June, the resulting cloud of particles taking 60 days to travel around the globe twice. Without any supporting evidence for the earlier event, this looks like special pleading. Indeed, the rather detailed estimates of the mass, velocity and other characteristics of the Tunguska meteorite, which Kondratyev says was a cometary nucleus composed largely of solid methane, seem to be plucked out of the air. Perhaps the primary literature is more convincing.

Kondratyev's account of the climatic consequences of nuclear war is largely built on selected early results, with an added emphasis on the possible effects of NO_x and other gaseous products. Like a number of other reviewers, he fails to identify clearly the critical role of absorption of solar radiation by carbon particles, as distinct from scattering. Use of the terms "optical depth" and "extinction", both of which include scattering as well as absorption, obscures the key point that most scattered light still reaches Earth's surface unless it is absorbed by the carbon particles. Thus on p.197 he quotes Crutzen and Birks as reporting solar radiation "extinction" by a factor of 2 to 150, when in fact they wrote that the "average sunlight penetration to the ground will be reduced by a factor of 2 to 150", which is quite different. This may be a fault in the translation, but it is a common misconception.

Other oddities may also be artefacts of translation — for example, a reference to 1815 as "a year without the sun" instead of "a year without a summer" (p.74).

With regard to the climatic consequences of nuclear war, Kondratyev, like many others, concentrates on the surface-temperature effects, giving too little emphasis to the perhaps more serious and robust results which show that rainfall would be dramatically reduced, especially in the tropics. He also fails to give proper attention to the importance of lofting of smoke due to its absorption of sunlight, and the resulting prolongation of the lifetime of the effects.

There is a natural and useful bias in the book towards the Soviet literature. But there is also a tendency to concentrate too much on results from Kondratyev's own group in Leningrad, and not enough effort is made at least to temper the view from Leningrad by comparing it with relevant non-Soviet studies. The treatment of the global carbon cycle is a case in point, with an extensive reference (p.12) to a controversial paper by Gorshov which claimed that "even after burning all existing fossil fuels, the CO_2 concentration in the atmosphere cannot increase by more than 35% to 40%". No contrary view is given.

In summary this is a confusing and somewhat partisan book, one which is perhaps more interesting for what it says implicitly about Soviet science than for what it contributes to an understanding of its subject matter. □

World enough and time

David E.H. Jones

The World of Mathematics: A Small Library of the Literature of Mathematics from A'h-mosé the Scribe to Albert Einstein. Commentaries and notes by James R. Newman. *Tempus Books, 16011 NE 36th Way, Box 97017, Redmond, Washington 98073–9717: 1956/1988. Four volumes, pp.2,448 plus indexes. Distributed by Harper & Row, hbk $99.95, pbk $50.*

In 1940 James R. Newman, a lawyer and writer who had trained as a mathematician, began to assemble a popular historical anthology of mathematical writings. He reckoned it might take him two years. Fifteen years later he delivered the million-word manuscript to his publisher: 133 entries, each with a brief introduction and biography of its author. *The World of Mathematics* finally appeared, in four volumes, in 1956. It was immediately successful — a classic of mathematical popularization. Now Tempus Books has reissued it, still in four volumes but this time in paperback as well as hardback form. How does it read in 1989?

The coverage, eclectic from the first, is beginning in parts to date. The broad historical background of mathematics is still excellent; the sections dealing with mathematics in the physical and social worlds, and with the bases of statistics, stand up for the most part remarkably well. But many of the entries concerned with pure mathematics and its cultural relevance would certainly have been reconsidered by Newman today. The intellectual level remains demanding but not intimidating: appropriate for the enquiring non-mathematician, or the mathematician off-duty. About 20 per cent of the entries are drawn from the research literature, or at least the primary presentation of original work; 30 per cent are educational or polemical pieces; 40 per cent are popularizations of established mathematics; and 10 per cent are stories, or whimsical or discursive essays.

The charm of a good historical anthology is the variety of outlooks and challenges it presents. Here is Francis Galton in 1869 discussing hereditary genius, blandly contravening all the principles of social justice by proving that some people are inherently many times brighter than others. Here is Malthus's famous essay of 1798 on population, condemning most of mankind for most of time to unavoidable misery — and where's the flaw in his argument? Here is Alan Turing in 1950 on whether a machine might think, an amazingly modern essay which still reads cogently after nearly 40 years of massive developments in computing. Newman was clearly a connoisseur of good literary style. Each of his selections can be read purely for pleasure, even without bothering to follow its argument. Anybody who reads the scientific literature should enjoy the book for this alone; anyone who writes it will probably blush for shame.

The whole huge compilation is far too big to take in at a sitting. It is a book for extended browsing, or a rather eccentric work of reference. I like best the entries dealing with mathematics in the real world. Lanchester on the mathematics of warfare, showing how Nelson's brilliant strategy at Trafalgar closely approached a theoretical optimum; Moseley's account of the X-ray identification of atomic number, probably his last paper before his tragic and pointless death at Gallipoli; Bernard Shaw on gambling and insurance — a departure from his usual concerns, but characteristically spirited and surprisingly sensible; John von Neumann on the workings of the neuron, and the analogy between the brain and the digital computer.

This new edition has not been reprinted. A copy of the 1956 Simon and Schuster publication has been optically scanned and digitally reset (the stupefying intellectual triviality of the tasks that occupy most modern computers would have saddened Turing and von Neumann). The index has been slightly modified; I have spotted just two words of additional text. The publishers have thus missed the opportunity to remedy the most infuriating omission of the first edition: the lack of bibliographical references to the entries. Some can be placed from Newman's commentaries, but many are quite free-floating. It is quite impossible to stand in proper relationship to a piece of writing if you don't know in what context, or crucially *when*, it was written. The annoying detective work needed to pin down each entry from Newman's introduction to it, or from other sources, is almost the only unpleasing feature of this marvellous book. □

Down to earth

Robert J. Devoy

Quaternary Geology for Scientists and Engineers. By John A. Catt. *Ellis Horwood: 1988. Pp.340. £39.50, $69.95.*

Quaternary geology (or, in a less partisan sense, Quaternary science) has long been the Cinderella of the earth sciences, attracting little attention as a discipline except from small national bands of enthusiasts. It is against this background that John Catt has produced a compact book of seven chapters that goes some way towards helping to redress the imbalance. The text presents information in a simple, practically orientated and narrative style, describing some of the subject's study themes, methodologies and techniques.

In some quarters, the book may not be received unreservedly. It is in places too much a catalogue of dry factual material. The treatment may also be viewed as overly selective and idiosyncratic, a situation which may have arisen from the author's aim of principally satisfying the needs of practical field scientists rather than those of specialists.

Against these criticisms, it should be remembered that non-specialists have to start somewhere. Despite the introductory approach the volume is not intended to be a definitive textbook, and the basic descriptive form will suit such non-specialist readers. Instead of a comprehensive overview, we have rather a helpful collection of working principles and definitions set within the framework of Quaternary data.

Quaternary science is an interdisciplinary and applied area of research. Its historical origin in nineteenth-century geology, coupled with the subsequent growth of specialisms, has too often led to a view of the subject as preoccupied with stratigraphy, gravels and an arid ordering of glacial–interglacial stages. It is refreshing, therefore, to see included here accounts of relevant specialisms which are clearly rooted in the aims and concerns of Quaternary studies. Geomorphology, soil science and dating techniques are all given chapter status alongside the coverage of basic stratigraphic approaches. A further innovation is the inclusion of chapters on mapping techniques and on the economic and applied importance of the Quaternary studies approach.

Regrettably some relevant areas, such as sea-level studies and palaeoecology, receive minimal and less than up-to-date treatment. Together with deficiencies in referencing the more advanced literature, these lacunae possibly reflect the author's own interests as well as the rapid advances in the literature concerned. Nonetheless the book's strengths outweigh its weaknesses. It contains an innovative and authoritative view of Quaternary science, and will be of great practical value to earth scientists. □

Robert J. Devoy is a Senior Lecturer in the Department of Geography, University College Cork, Ireland.

• Newly published by Unwin Hyman is *Chemical Fundamentals of Geology*, by Robin Gill, intended for geology students and others wanting to get to grips with 'geo-relevant' chemistry.

M

GUIDE TO AUTHORS

Please follow these guidelines so that your manuscript may be handled expeditiously.

Nature is an international journal covering all the sciences. Contributors should therefore bear in mind those readers for whom English is a second language and those who work in other fields. Please write clearly and simply, avoiding unnecessary technical terminology. *Nature*'s staff will edit manuscripts to those ends if necessary. Contributors should check their proofs carefully.

Because of the competition for space, many of the papers submitted for publication cannot be accepted. For this reason, and because brevity is a great assistance to readers, papers should be as brief as is consistent with intelligibility. Please note that one printed page of *Nature*, without diagrams or other interruptions of the text, has fewer than 1,300 words.

CATEGORIES OF PAPER

Review Articles survey recent developments in a field. Most are commissioned, but suggestions are welcome in the form of a one-page synopsis addressed to the Reviews Coordinator. Length is negotiable in advance but must not exceed six pages of *Nature*.

Articles are research reports whose conclusions are of general interest and which are sufficiently rounded to be a substantial advance in understanding. They should not have more than 3,000 words of text or more than six display items (figures and tables) and should not occupy more than five pages of *Nature*.

Articles should be accompanied by a heading of 50 – 80 words written to advertise their contents in general terms, to which editors will pay particular attention. A heading (printed in italic type) is not an abstract and should not usually contain numbers or measurements. The study should be introduced in more detail in the first two or three paragraphs, which should also briefly summarize its results and implications.

Articles may contain a few subheadings of two or three words. The meaning of the text should not depend on the subheadings, whose function is to break up the text and to point to what follows. There should be fewer than 50 references.

Letters to Nature are short reports of outstanding novel findings whose implications are general and important enough to be of interest to those outside the field. Letters should not have more than 1,000 words of text or more than four display items and should not occupy more than two pages of *Nature*. The first paragraph should describe, in not more than 150 words, the origins and chief conclusions of the study. Letters should not have subheadings or more than 30 references.

Commentary articles deal with issues in, or arising from, research that are also of interest to readers outside research. Some are commissioned, most are unsolicited. They are normally between one and four pages of *Nature* in length.

News and Views articles are intended to inform non-specialist readers about a recently published advance. Suggestions should be made to the News and Views Editor. Illustrations are welcome. Proposals for meeting reports should be agreed in advance.

Scientific Correspondence is for the discussion of scientific matters, including contributions published in *Nature*. Priority is given to contributions of less than 500 words and five references. Figures are welcome.

GENERAL

All contributions submitted for publication in *Nature* should conform with these rules.

Manuscripts should be typed, double-spaced, with a good-quality printer, on one side of the paper only. Four copies are required, each accompanied by lettered artwork. Four copies of half-tones should be included. Reference lists, figure legends and so on should be on separate sheets, all of which should be double-spaced and numbered. Copies of relevant manuscripts in press or submitted for publication elsewhere should be included, clearly marked as such. Revised and resubmitted manuscripts should also be clearly marked as such and labelled with their reference numbers.

Titles should say what the paper is about with the minimum of technical terminology and in fewer than 80 characters. Authors should avoid active verbs, numerical values, abbreviations and punctuation and should include one or two key words for indexing purposes.

Artwork should be marked individually and clearly with the author's name, figure number and, when known, manuscript reference number. Original artwork should be unlettered. Ideally, no figure should be larger than 28 by 22 cm. Figures with several parts are permitted only if the parts are closely related, either experimentally or logically. Suggestions for cover illustrations, with captions, are welcome. Original artwork (and one copy of the manuscript) will be returned when a manuscript cannot be published.

Colour Artwork. A charge of £500 a page is made for 4-colour figures. Inability to meet these costs will not prevent the publication of essential colour figures if the circumstances are explained.

Figure legends must not exceed 300 words and ideally should be much shorter, and should use telegraphic form wherever possible. The figure should be described first, then, briefly, the method. Reference to a method described elsewhere is preferable to a full description. Methods should not be described in detail in the text.

References should be numbered sequentially as they appear in the text, followed by those in tables and finally those in the figure legends. Reference numbers apply only to papers published or in the press, and a different number should be given to each paper cited. All other forms of reference (including unrefereed abstracts) should be included in the text as personal communication, manuscript in preparation or preprint (with number and institution where appropriate). Text should not be included in the reference list. References should be abbreviated according to the *World List of Scientific Periodicals* (fourth edition, Butterworth, London, 1963 – 65). The first and last page numbers should be cited. Reference to books should clearly indicate the publisher and the date and place of publication.

Abbreviations, symbols, units and Greek letters should be identified the first time they are used. Acronyms should be avoided as much as possible and, when used, defined. Editors will shorten words if necessary. In case of doubt, SI units should be used.

Footnotes should not be used except for changed addresses or to identify the corresponding author if different from the first-named.

Acknowledgements should be brief. Grant numbers and contribution numbers are not allowed.

Submission. *All manuscripts may be submitted to either London or Washington. They should not be addressed to editors by name. Manuscripts or proofs sent by air courier to London should be declared as 'manuscripts' and 'value $5' to prevent the imposition of import duty and value-added tax (VAT).*

Penury and potential in Venezuela

Maxine Clarke

Five years ago Venezuela's currency collapsed. Since then the country's researchers have been doing science on a shoestring.

TODAY, 2 February, Venezuela acquires a new president, Carlos Andres Perez, victor of the general election held in December after a year-long campaign. He inherits a stable and, in Latin American terms, remarkably democratic political system. Since the end of the dictatorship in 1958 there has been little organized unrest, and the collapse of the guerrilla movement in the mid-1970s heralded almost ten years of stability. On 'Black Friday' in October 1983, the currency fell from about three bolivars (Bs) to the US dollar to its present thirty-five. Almost overnight, imported goods became impossible to obtain and foreign travel became prohibitively expensive.

Carlos Perez — unlikely to have a science policy.

Before 1983, oil had propped up the country virtually unaided. But when the oil prices collapsed, escalating interest rates set by international banks crippled the economy. Another 50 per cent devaluation seems to be on the way. In his previous administration (1974–1979), Perez nationalized the oil industry and ended the social unrest of the 1960s by inviting guerrilla leaders to join his government. Hopes that he will repeat the trick for the present crisis were pre-empted by the outgoing president Jaime Lusinchi, who last month announced that Venezuela will stop paying the principal on about $20,000 million of its outstanding foreign debt to international banks.

Science inevitably takes a back seat in such economically crisis-ridden times. Perez will probably appoint Jaime Requena as his science minister, but the administration is unlikely to have a science policy. Some Venezuelans think this only realistic given the economic problems. Others believe that investment in research is essential for the future, particularly in developing the nascent aluminium, hydroelectric power and plastics industries.

Although there are many excellent scientists in Venezuela, the government's organization of the research effort is a shambles. Apart from CONICIT, a body that is Latin American rather than having evolved specifically in Venezuela, there is no organized, national system for awarding grants by scientific merit. Decisions are left up to individual directors of institutes or rectors of universities. Some of them do indeed apply professional criteria in distributing the limited funds available, but the lack of accountability means that others need not be so scrupulous. 'Administrative' costs, for example, can swallow up huge proportions of an institution's budget. Unpopular individuals can fail to have their projects supported, and projects can be supported for political, rather than scientific, reasons. Most researchers who have jobs have them for life, a situation open to abuse. □

These articles are based on a recent visit to Venezuela by Maxine Clarke, Nature*'s Features Editor. Thanks are due to her host Maria Centeno, and also Carlo Caputo, Nora Castaneda, Stephen Garner-Winship, Erica Jaffe, Raul Padron and Jorge Villegas.*

The institutes: self-help is the answer

EACH of Venezuela's research institutes is responsible to the ministry that founded it. IVIC, the institute for scientific investigation, is the largest. Others are IDEA, the institute of advanced studies; INTEVEP, the oil institute; FONAIP, the agricultural institute; FII, the engineering institute; and CAICET, the Amazon research institute. Most of these do not support much basic research. CAICET, for example, is mainly involved in health programmes.

As in other South American countries, research in Venezuela is administered by CONICIT, which has a budget of some 180 million Bs (about $5 million) per year. About a third of this is available to scientists who apply for grants, another third goes on students and equipment, and another third on administration. Many scientists are critical of CONICIT for spreading these meagre resources too thinly on new programmes rather than continuing to support existing projects.

Even by its rivals IVIC is said to be the best research institute in Latin America. The problems it faces are typical of the conditions faced by scientists in post-crash Venezuela. It is under the control of the minister of health, who appoints the director, who then can appoint heads of department, distribute the annual budget as he wishes and so on. The staff at IVIC elect a new director every four years, but there have been occasions when the scientists' choice has been ignored — if the candidate belongs to the wrong political party, for example. The government ministers themselves are often ex-scientists who have decided on a political career in order to implement their ideas about what sort of science should be done, a system that leads to frustration among those researchers who feel that their careers are being directed by people who have some grand scheme in mind, rather than those who will take notice of project applications from the grass-roots level.

This frustration has resulted in fragmentation of resources. Two breakaway institutes have been set up by IVIC scientists who in the past have disagreed with the way the institute is run: INTEVEP, which was formed by members of the chemistry department, and IDEA (see below).

IVIC receives an annual budget from the government of 300 million Bs (about $8·5 million). There are 12 scientific departments, called centres, service departments and administrative offices. The institute also provides facilities such as accommodation, a kindergarten, a national guard post, a bank and that Venezuelan rarity, a post office.

In the past few years the budget has become inadequate for IVIC to function effectively — the money has to pay for 100 scientists, their support staff, equipment and running costs. So other sources of income are being sought. IVIC's director, the neuroscientist Horacio Vanegas, is involved in discussions with various international science organizations and the Andean Development Corporation (CAF), a biotechnology development organization. Shopping around in this fashion is

still alien to Venezuelans, many of whom have not come to terms with the fact that since 1983 the country is no longer relatively wealthy. Other Latin American countries, such as Brazil and Costa Rica, have set up links with international funding agencies, but oil-rich Venezuela has not, and suffers from being perceived as prosperous by the outside world.

A typical salary for an established staff scientist is about $350 a month, and the 100 researchers at IVIC have to share $1 million a year for running costs, equipment, technicians' salaries and so on. Many of the researchers have been graduate students or postdocs in universities in the United States and in Europe, and some manage to obtain funds using the contacts they have made there. Others have begun collaborative projects, enabling exchange visits. "It's a pity we aren't baseball players", said one researcher, "then there would be plenty of government money available." (Baseball is the national sport, and its teams are conspicuously well-sponsored.)

IVIC provides various courses for undergraduates from the Central University in Caracas, about 150 of whom each year go on to study for higher degrees. When IVIC first began to run PhD courses in the 1970s, the universities refused to recognize the institute's right to award the degree. IVIC's response was a typical piece of Venezuelan pragmatism; it simply renamed the degree PhSc (philosophus scientius).

Unofficial responses

The researchers themselves have developed many unofficial responses to the economic crisis in which they now find themselves. Officially, there is a preferential exchange rate for government employees of 14.5 Bs to the US dollar rather than the commercial rate of 35 Bs. But any researcher trying to obtain equipment or materials using this method will experience horrific bureaucratic delays. There are stories of how companies have gone bankrupt between receipt of an order and the payment of the cheque (stopping the process at this point is virtually impossible). There is no efficient way by which customs identifies the goods as different from commercial goods, so degradable chemicals, including isotopes, can be delayed for months. It is not surprising that smuggling is the most common way by which scientists obtain the tools of their trade. One brought in his computer with the help of a brewery, whose beer is the only brand IVIC staff will drink.

Many people have built their own equipment out of the materials they have to hand; jury-rigged modem connections are common, and one researcher had made an optical diffractometer using parts of his own camera. This same person built a rotating-anode X-ray generator out of parts ordered painstakingly slowly from a British company, and then built an office on the top of the machine.

Vanegas, caught between his frustrated scientists used to better times and an unsympathetic government, emphasizes self-help as the only way forward. For the first time in the institute's 30-year history, he is going to produce a five-year plan to identify potentially fruitful areas of research. He is particularly keen on biotechnology, both plant and medical, as an area to attract funds and one that will reap rewards in the future. He is also proud of his institute's technology centre, which provides an analytical service for which it charges. He believes the service provided cannot be bettered anywhere in Latin America, and now that industries and hospitals are unable for financial reasons to send samples for analysis outside the country, they are beginning to use the IVIC service routinely. The profits are divided equally between the institute, the laboratory that has provided a particular test and the people who perform the test. Last year, the centre made 4·5 million Bs ($130,000) profit.

But at IVIC as elsewhere in the country, science is done in an eccentric and personal way. Instead of groups of researchers working on related aspects of a problem, such as can be found in any institution in the United States or Europe, individuals work on their own project, acquiring research students and technicians, rather than collaborating with other institutions and making the best use of resources. The physics department at IVIC is an exception to the rule, mainly as a result of an attempt to bring together all Venezuelan experimental physicists into one centre. The ratio of theoretical to experimental physicists at IVIC is about 50/50, compared with 80/20 at the universities and 90/10 among graduate students. Miguel Octavio of the cold-temperature laboratory at IVIC says that only one doctorate in experimental physics will be awarded in Venezuela in the next three years, compared with about 30 theoretical degrees.

Octavio has worked on superconductivity for many years, and has been a wry observer of the explosion of the field since the breakthrough made in 1986. Because of his contacts at MIT, where he used to work, he manages to keep in touch. But to use his undoubted expertise in the field to do research on the high-critical-temperature materials, he needs money, and this is conspicuously lacking.

Despite the lack of any compelling reason to do good science — low salaries, nepotism and the difficulty of obtaining materials and information — many people are doing excellent research. This is most apparent at IVIC, where the laboratories are bustling, busy places. Many have taken a conscious decision to abstain fro the in-fighting for privilege and try to d the best research and teach as man students as possible, in preparation fo better times. But with their experience o how the country, and its science, are run few are optimistic; IVIC has lost one quarter of its staff to positions abroad i the past five years.

IDEA for change

The institute of advanced studies (IDEA stemmed from acrimony in the 1960s The then director of IVIC, Raymund Villegas, conceived the notion of an insti tute to study the development of scienc and the interface between science and th arts. When Villegas became minister o science in 1979, he persuaded the govern ment to set up a new institute, and took with him from IVIC his two brothers Jorge and Leopoldo, and one or two othe scientists.

Before the present director, the philosopher Luis Castro, took over in 1985, there were seven scientists and one researcher from the humanities at IDEA. In the past three years, Castro has appointed six more staff from the humanities: an artist, a philosopher, a political scientist and a cultural anthropologist among them. Castro wants to promote the interdisciplinary approach, and create an environment where art and science can meet. The laboratories at IDEA contain plenty of equipment but a marked absence of people to operate it — unlike laboratories in the universities, hospitals and at IVIC, where there are more people than facilities.

IDEA receives a grant of six million Bs ($170,000) a year, which Castro says is inadequate on its own to run the institute. When it was founded, at a time when the economy was in a better state, IDEA was intended to be an international conference centre, thus generating income of its own. Castro believes that conferences could still be the saving of the institute, pointing out the financial attraction now that the bolivar is so weak.

He stresses that Venezuela has much to offer scientists around the world: there are many unique natural features waiting to be studied, few regulations to restrict experimental programmes (although the bureaucracy of the government is another matter) and a great deal of scientific talent that is eager to undertake international collaboration. The researchers themselves are more sceptical. The troubled World Archaeology Congress is scheduled to hold its next meeting in Venezuela, at the University of Los Andes. But there is not much grass-roots enthusiasm for hosting an event that has become so politically sensitive. Already the manoeuvring over the organization of the congress has begun, diverting energies that would be better spent on research. □

The universities: looking to local relevance

VENEZUELA's university system is in imminent danger of collapse. From January to May last year, the system was paralysed by a strike of teachers, other staff and students. No classes were held. The cause was the government's failure to keep its promise, made in 1982, to keep staff salaries index-linked to inflation. The strike ended when the government proposed a compromise budget to be implemented last autumn; although university staffs are now back at work, they fear that the worsening economic situation will again allow the government not to keep its promises.

Yet Venezuela has an excellent tradition of university education, in principle free to all. There are 16 public universities and seven small private universities. Venezuela's 'Ivy League' are five 'autonomous' public universities, of which the most important is the Central University in Caracas (UCV), with 50,000 undergraduates. The others are the universities of Zulia, Los Andes, Caribibo and Oriente.

But free university education does not mean free access; in the absence of government loans or grants for the less well-off, higher education remains only a dream for many. Nonetheless, altogether there are more than 300,000 students in Venezuela.

The remaining public universities, set up in the 1960s, are called 'experimental' universities. They were founded at a time when there was much student activist support for anti-government guerrilla forces. At UCV the government converted all the halls of residence into classrooms, an arrangement that still persists, even though student radicalism is now limited to the vocal. The experimental universities have fewer constitutional rights than the autonomous universities, because each one is under the control of the government minister who set it up.

The universities' dispute was triggered by a request for a special loan for running expenses, which the universities were finding hard to meet. When the request was turned down, the strike began, with staff demanding the promised cost-of-living increases, which have not been provided since 1982. In the past three years the cost of living has increased by more than 40 per cent per year. Once the strike began, the students joined in, demanding an improvement in services such as libraries, transport, food and so on.

Postgraduate studies are in an even worse state than undergraduate courses. At UCV, for example, every faculty has a centre for postgraduate studies, but each one has only very few students. Most of them are studying for masters' degrees; there are only a handful of PhD students. The new rector of UCV, Luis Fuenmayor Toro, is trying to increase the numbers of masters' and doctoral students from the present two per cent of the total number of students at UCV. He also wants PhD students to be more research-based instead of class-taught, as many of them are at present.

Toro believes that one approach to the seemingly desperate economic problem is to emphasize research that is of direct relevance to the Venezuelan people. Many researchers are aware of the need to form partnerships with international colleagues, and feel that Venezuela in better times has perhaps taken a rather haughty view of the rest of South America, a luxury it can no longer afford.

Tony Morrison

A cheerful mural at the Central University in Caracas. But university staff remain dissatisfied.

The government invests about 7,000 million Bs ($200 million) per year on higher education (this figure includes teachers' training). The universities regard this as inadequate, mainly in view of the inflation of the past few years, which has not been mirrored by a corresponding increase in their budgets. The cabinet decides the annual education budget, which is then approved by congress. Once approved, the money is distributed to all the universities by the National Council of Universities. This is done on the 'night of biting' in which each university tries to get the best share. The autonomous universities generally obtain most of the money, but the experimental universities have another potential source of funds: the minister for education. It has become a tradition that the minister of education in a particular administration creates his own experimental university, with a political appointee as dean.

By far the largest and best of the experimental universities is Simon Bolivar University (USB), which supports about 6,000 undergraduate students and 1,000 graduates. The buildings and grounds are beautifully maintained, and the colonial-style architecture betrays the origins of the campus — first a coffee plantation, then in turn a farm for sugar, horses, flowers and now, the joke goes, students. It was set up 21 years ago in response to the guerrilla activities of the students at UCV. Situated well outside the city, the only public transport to civilization from USB is an irregular half-hourly bus.

The science departments concentrate on technical subjects, particularly computing studies, information technology, metal alloys, physical chemistry and food chemistry. Biology was born relatively late here, but the department has learnt to optimize its resources, according to Dr Klaus Jaffe, by taking advantage of Venezuela's wealth of natural diversity. Hence there is a palaeontology group investigating dinosaur and other fossils; and ecology, marine biology and parasitology departments (although no molecular biology department, not least because up-to-date equipment would be impossible to buy and maintain). Much of the research done here is published in the international literature.

Jaffe believes that the autonomous universities are too large for effective management, and says that the system at USB for distributing money and choosing officials is at least as free as it is in the autonomous universities. The academic staff of the university suggest three names to the government when a new dean is to be elected, and the government selects one of these names. Money awarded to the university is distributed internally according to strict criteria such as productivity, as well as in start-up grants for new researchers. The university receives about five million Bs (about $140,000) a year for research. This amount is supplemented by the energy of individual researchers, who obtain grants from overseas, particularly Sweden, Japan, Canada and the United States, as well as getting a piece of the small cake distributed by CONICIT. The foreign research money takes almost any form one cares to imagine, from Swedish 'pocket money' to full-blown grants from the National Science Foundation as part of that organization's US–Latin America research scheme. Jaffe says that this constant searching around for money is yet another handicap for scientists in the developing world struggling to keep up with the international pace. □

Segmental patterns of neuronal development in the chick hindbrain

Andrew Lumsden & Roger Keynes

Department of Anatomy, United Medical and Dental Schools, Guy's Hospital, London SE1 9RT, UK and Department of Anatomy, Downing Street, Cambridge CB2 3DY, UK

Identification of specific neuronal populations and their projections in the developing hindbrain reveals a segmental organization in which pairs of metameric epithelial units cooperate to generate the repeating sequence of cranial branchiomotor nerves. Neurogenesis also follows a two-segment repeat, suggesting parallels with insect pattern formation.

THE remarkable diversity of function produced by the vertebrate CNS is based on regional variations in the identity, arrangement and connectivity of nerve cells. A major aim of neurobiology is to understand how such variations develop. One possibility is that cells are organized into repeating groups, or segments, along the antero-posterior (A-P) axis, allowing each segmental population to individuate from its neighbours. Although segmentation is prominent in the development of many invertebrates[1-4], its contribution to vertebrate development is less clear cut. During this century at least, only the somitic and nephrogenic mesoderm have been regarded as being properly segmented, but it is possible that segmentation is also an important pattern-forming process within the neural epithelium, where transient periodic swellings, neuromeres, have long been recognized[5-7]. In higher vertebrates, neuromeres are particularly conspicuous in the developing hindbrain; an extensive literature has described these 'rhombomeres' in the embryos of many species, amongst which the numbers and arrangement of swellings are constant (reviewed in refs 8, 9). The original descriptions of rhombomeres culminated in two opposing views of their significance, clearly outlined in 1918 by Neal[7]: first, 'the non-phylogenetic interpretation that neuromeres are either a) artifacts due to the action of fixing agents or, b) transient embryonic structures resulting either from longitudinal compression of the neural tube or to the local strain of related nerves'; and second, 'the phylogenetic interpretation that neuromeres are the visible remnants of a primitive segmentation of the nervous system and consequently reliable clues to the original number of metameres in the vertebrate head'. There have been surprisingly few attempts to relate this gross pattern of swellings to any underlying patterns of neuronal development[7,10,11]. Some authors did suggest that there may be a correlation between the development of particular cranial nerve nuclei and their origins from individual rhombomeres[8,10,11], but others disputed such relationships[7]. This uncertainty was probably a result of limitations in the techniques available at the time. An understanding of the significance of rhombomeres will require the elucidation of their cellular basis. This is also necessary for the interpretation of the expression patterns of genes with putative regulatory roles during the regionalization of higher vertebrates. Many mouse homoeobox genes, for example, have boundaries of expression that lie within the developing hindbrain[12-17].

Here we show that the neuronal pattern of the chick hindbrain does develop on a segmental basis, and that the early arrangement of the cranial nerve nuclei reflects these segmental origins. We find, moreover, that the pattern of hindbrain segmentation shares certain features with the segmentation process described in organisms such as *Drosophila melanogaster*.

Segmental patterns

Rhombomeres arise between stages 9 and 12 and persist up to stage 24 (ref. 9; Fig. 1*a*). When the full complement of rhombomeres has been generated, the neural epithelium is subdivided into repeating units by an iterative pattern of neurogenesis. The first neurons appear within alternate rhombomeres. At stages 13–14, axons of these reticular neurons are most numerous in rhombomeres 2, 4 and 6 (r2, r4, r6), whereas neurofilament immunoreactivity in r1, r3 and r5 is mostly confined to cell bodies of newly-differentiated neurons (Fig. 1*b*, *c*). At stage 16 the alternating density of neurofilament staining is maintained by the growth of motor axons within the even-numbered rhombomeres (Fig. 1*d*, *e*). Between stages 16 and 17 this alternation diminishes as motor axons also begin to appear in the odd-numbered rhombomeres (Fig. 1*f*).

Rhombomere boundaries

Transversely oriented boundaries between adjacent rhombomeres are revealed by concentrations of axons visible in neurofilament-stained preparations from as early as stage 13 (Figs 1*b*, 2*a*). In the boundaries, large numbers of neurones differentiate beneath the segmental ridges of the ventricular surface.

As medially-directed axons approach the midline floor plate, many turn into the medial longitudinal pathway, contributing projections to other CNS regions. Such axons are particularly concentrated at the r4/5 and r5/6 boundaries (Fig. 1*b–e*). Other axons continue to grow across the floor plate before turning into the contralateral medial longitudinal pathway (Fig. 1*e*).

At the boundaries, neuronal cell bodies and axons populate embrasures underlying the ventricular ridges (Fig. 2*b*). The intercellular spaces in these regions are large compared with those in the adjacent neural epithelium (Fig. 2*c*, *d*). Moreover, they are distinguished by speckled immunoreactivity to the extracellular matrix glycoprotein laminin (Fig. 2*e*). Expression of the highly sialylated neural cell adhesion molecule N-CAM in the ventricular layer, in contrast, is localized to the central regions of rhombomeres (Fig. 2*f*). Finally, Ng-CAM/L1 is expressed at the rhombomere boundaries (Fig. 2*g*).

The boundaries between rhombomeres are therefore distinct from the central regions; the large intercellular spaces may permit axons to extend preferentially, thereby forming discrete segmented pathways across the transverse axis. The local expression of laminin suggests another way in which this process may be facilitated and Ng-CAM/L1 expression suggests that some axons fasciculate when growing in these transverse pathways.

Cranial nerve roots

The exit points of the cranial nerves occupy distinct positions in relation to individual rhombomeres (Figs 1*c*, *f*, 4). The Vth (trigeminal) nerve root, for example, lies in r2 and the VIIth (facial) nerve root lies in r4. In each case, the root lies in the central furrow of the rhombomere, between the two boundaries. Injection of the fluorescent tracer DiI into the Vth, VIIth and IXth (glossopharyngeal) roots reveals a tight correspondence between the position of each branchial motor nucleus and the

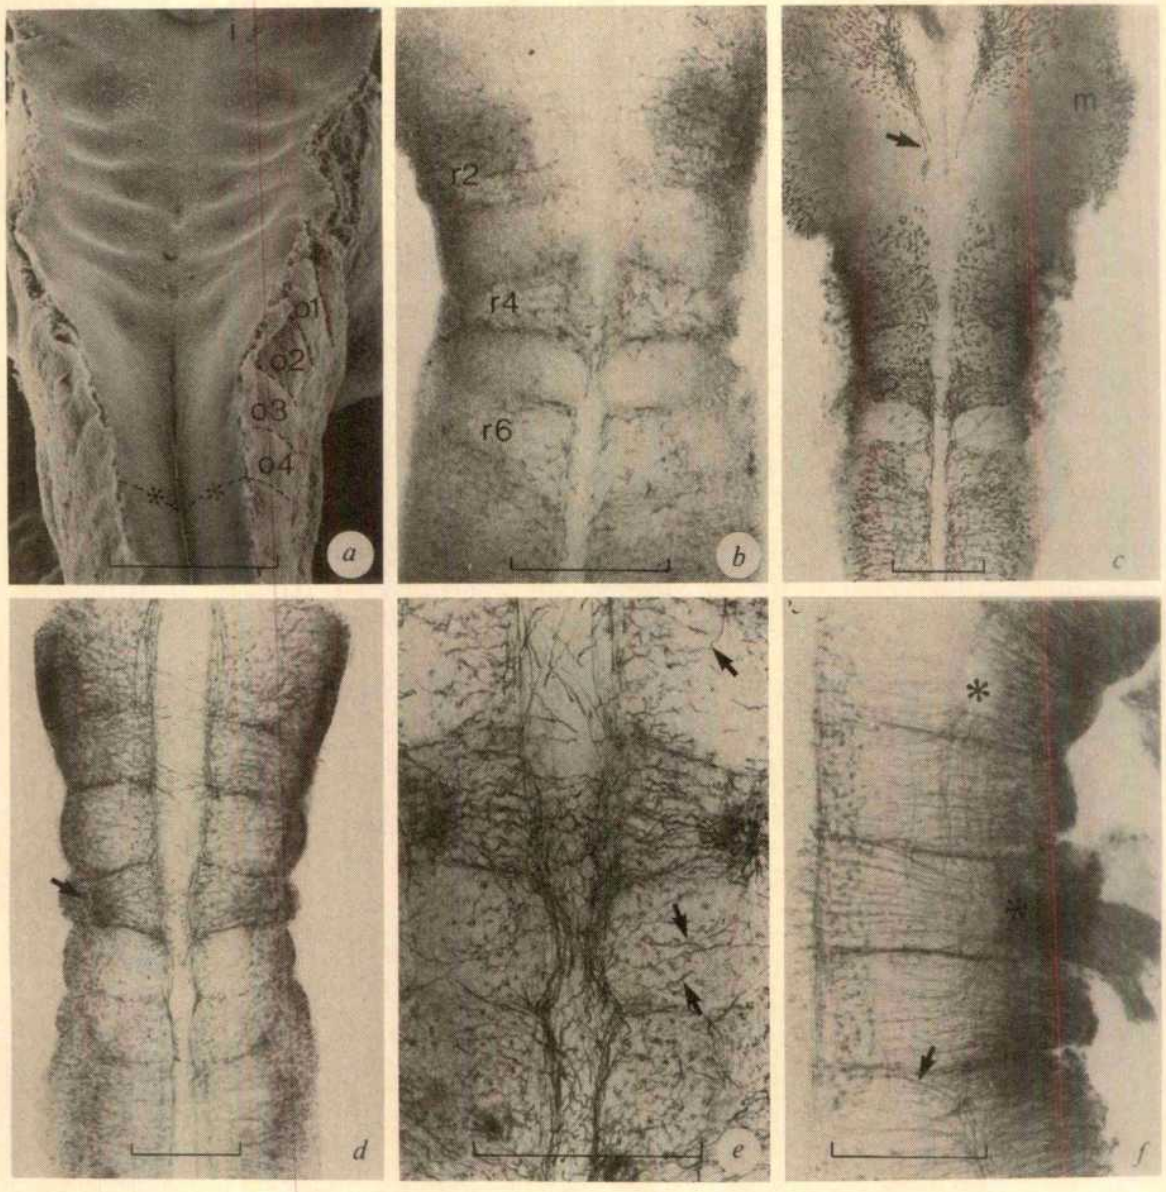

Fig. 1 *a*, Scanning electron micrograph of the chick embryo hindbrain at HH stage 17 (ref. 33). The ventricular (inner) surface of the hindbrain is exposed by removal of the roof plate. A smooth sinusoidal pattern of transverse ridges and furrows is visible along the A–P axis. The ridges do not extend into the midline floor plate. Between the midbrain/hindbrain boundary (isthmus, i) and the hindbrain/spinal cord boundary (*) there are six ridges alternating with seven furrows on each side of the midline. Rhombomeres 2–6 each comprise a furrow flanked by two half-ridges. R7 and r8 lie alongside the four occipital somites (o1–o4). Before stage 15, a ridge separates these two last rhombomeres at the level of the cleft between the first two somites[9]. Scale bar, 300 μm. Fig. 1*b–f*, Whole-mounted neurofilament-stained brainstem preparations dissected from chick embryos of stages 13–17, viewed from the pial (outer) aspect. Scale bars, 300 μm. *b*, Stage 13. Rhombomeres 2, 4 and 6 are indicated, and are distinguished from r1, r3, r5 and r7 by their greater neurofilament immunoreactivity of reticular neurons; axons are also prominent at boundaries. Some axons turn in a posterior direction at the margin of the floor plate. *c*, Stage 14. Neurons have now differentiated in r1, r3, r5 and r7, whereas many axons have appeared in the even-numbered rhombomeres. The midbrain–hindbrain boundary is seen as a sharp change in density of neurofilament staining. In the midbrain, axons are descending from the diencephalic nuclei of the medial longitudinal fasciculus (mlf, arrowed). Neurons in the mesencephalic tectum (m) are extending axons. *d*, Stage 16. The boundaries between rhombomeres contain clusters of axons, particularly at r1/2, r2/3, r3/4 and r4/5. The root of the VIIth nerve (arrowed) is visible in r4; other roots have been avulsed. The medial longitudinal pathway extends along the length of the hindbrain, adjacent to the floor plate. Commissural reticular axons enter the floor plate from the medial ends of rhombomere boundaries. *e*, Stage 16$^+$. The exit point of the VIIth nerve is visible in r4, which is packed with motor axons (compare with Fig. 3*b*). Motor axons (arrowed) are also beginning to develop in r3 (Vth nerve) and r5 (VIIth nerve). Many boundary axons lie outside this focal plane. *f*, Stage 17. Motor axons course laterally in r2 and r4 to reach the exit points (*) of the Vth and VIIth nerves. Axons of these nerves are also visible in r3 and r5, and describe an arcuate, anteriorly-directed trajectory. Axons of the IXth nerve (arrowed) originate posterior to the r5/6 boundary.

Methods. For whole-mount neurofilament staining, embryos were immersion-fixed for 24 hours in 4% paraformaldehyde in 0.1 M phosphate buffer *p*H 7.2 at 4 °C. Endogenous peroxidase was blocked by immersion in phosphate-buffered saline (PBS) +0.05% hydrogen peroxide overnight at 4 °C, followed by incubation in anti-68K neurofilament antibody (gift of Dr P. Hollenbeck) + 1.0% Triton X-100 for 4 days at 4 °C. Embryos were then incubated overnight in peroxidase-conjugated donkey anti-rabbit immunoglobulin (Amersham), followed by immersion in diaminobenzidine (DAB, Dotite, 500 μg in 1 ml Tris pH 7.3) for 3 hours at 4 °C in the dark. Hydrogen peroxide was then added and the DAB reaction product developed at room temperature. The hindbrains were then dissected from the embryos, freed of pial cells, and cut down the dorsal midline. They were then splayed out like kippers to present the entire pial surface, and mounted, without flattening, in cavity slides in 90% glycerol + 10% PBS + 0.02% sodium azide.

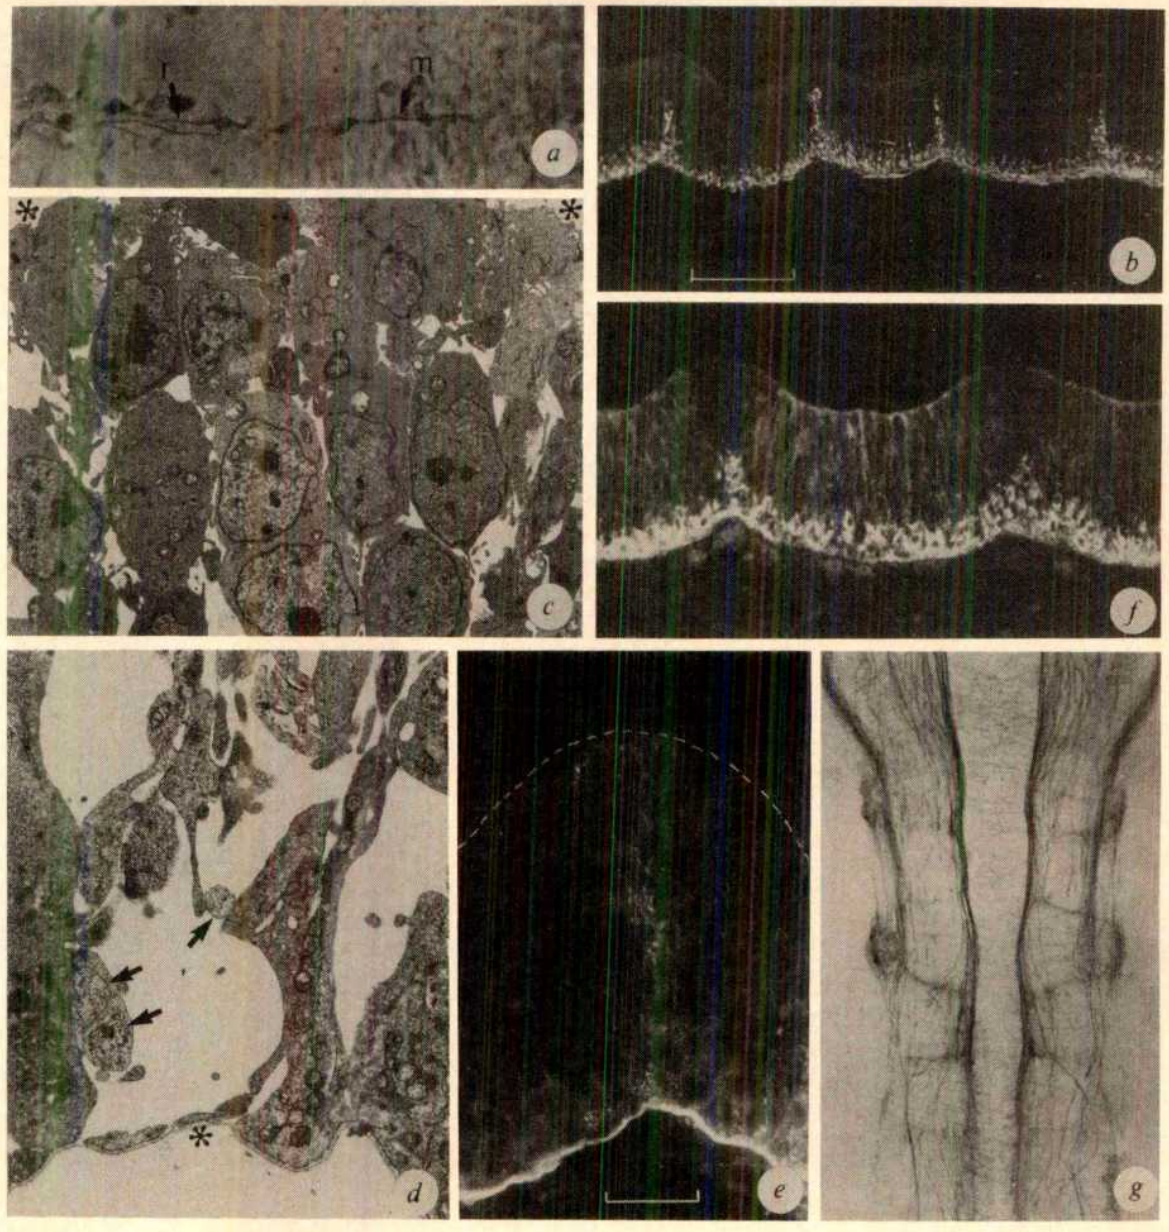

Fig. 2 *a*, Whole-mount stage-16 preparation prepared as described in the Fig. 1 legend, showing reticular (r) and motor (m) neurons lying at a rhombomere boundary. Medial is to the right. The focal plane is just beneath the ventricular surface. *b*, Parasagittal section of stage-17 hindbrain, stained by the indirect immunofluorescence method using anti-68K neurofilament antibody. At the boundary regions, the mantle layer extends towards the ventricular surface in a delta-shaped embrasure. These dorso-ventral bands of neurofilament immunoreactivity underlie the ventricular ridges. Scale bar, 100 μm. *c*, *d*, Parasagittal transmission electron micrograph of a stage 16 boundary region, showing the ventricular surface (*, *c*, ×1,890) and the pial surface (*, *d*, ×5040). The intercellular spaces are distinctly larger near the pial surface and contain several axon profiles (arrowed). *e*, Parasagittal section of stage 17 hindbrain, stained by the biotin-streptavidin amplified indirect immunofluorescence method, using affinity purified anti-laminin antibody[34] (JW1, gift of Dr J. Winter). A punctate distribution of laminin immunoreactivity is localized to the boundary region. The speckled immunofluorescence extends throughout the medio-lateral extent of each rhombomere boundary. The ventricular surface is indicated. Scale bar, 25 μm. *f*, Parasagittal section of stage 17 hindbrain, stained by the indirect immunofluorescence method, using monoclonal anti-N-CAM antibody (5A5, directed against highly sialated form, gift of Dr T. Jessell). Immunoreactivity in the ventricular layer is localised to the central furrows of rhombomeres. Neurons also express N-CAM. *g*, Whole-mount stage 17 hindbrain, stained by the modified indirect immunoperoxidase method described in the Fig. 2 legend, using monoclonal anti-Ng-CAM/L1 antibody (8D9, ref. 35 gift of Dr V. Lemmon). Axons express Ng-CAM in both longitudinal pathways and the transverse boundary pathways.

rhombomeric pattern. In a series of injections into 90 embryos, we examined how this correspondence evolves between stage 16, when motor neurons first become traceable by injections outside the brain, and stage 24, when motor neurogenesis and migration are complete.

At stage 16, motor cell bodies of the Vth nerve lie exclusively within r2 (Fig. 3*a*), those of the VIIth in r4 (Fig. 3*b*) and those of the IXth in r6. In each case, the neuronal group spans the A–P length of the rhombomere, and the axons converge towards their exit point as they course laterally in the marginal layer.

At stage 17 the number of retrogradely-labelled neurons in r2, r4 and r6 has increased, and neurons originating from the alternate rhombomeres (r3, r5, r7) are also labelled (Fig. 3*c*, *d*). In the case of each branchiomotor nerve, therefore, the first axons arise from the rhombomere containing the nerve root, whereas later axons also arise from the posteriorly adjacent rhombomere (see also Fig. 3*e*). The pathway of motor axons in the odd-numbered rhombomeres is different from that in even-

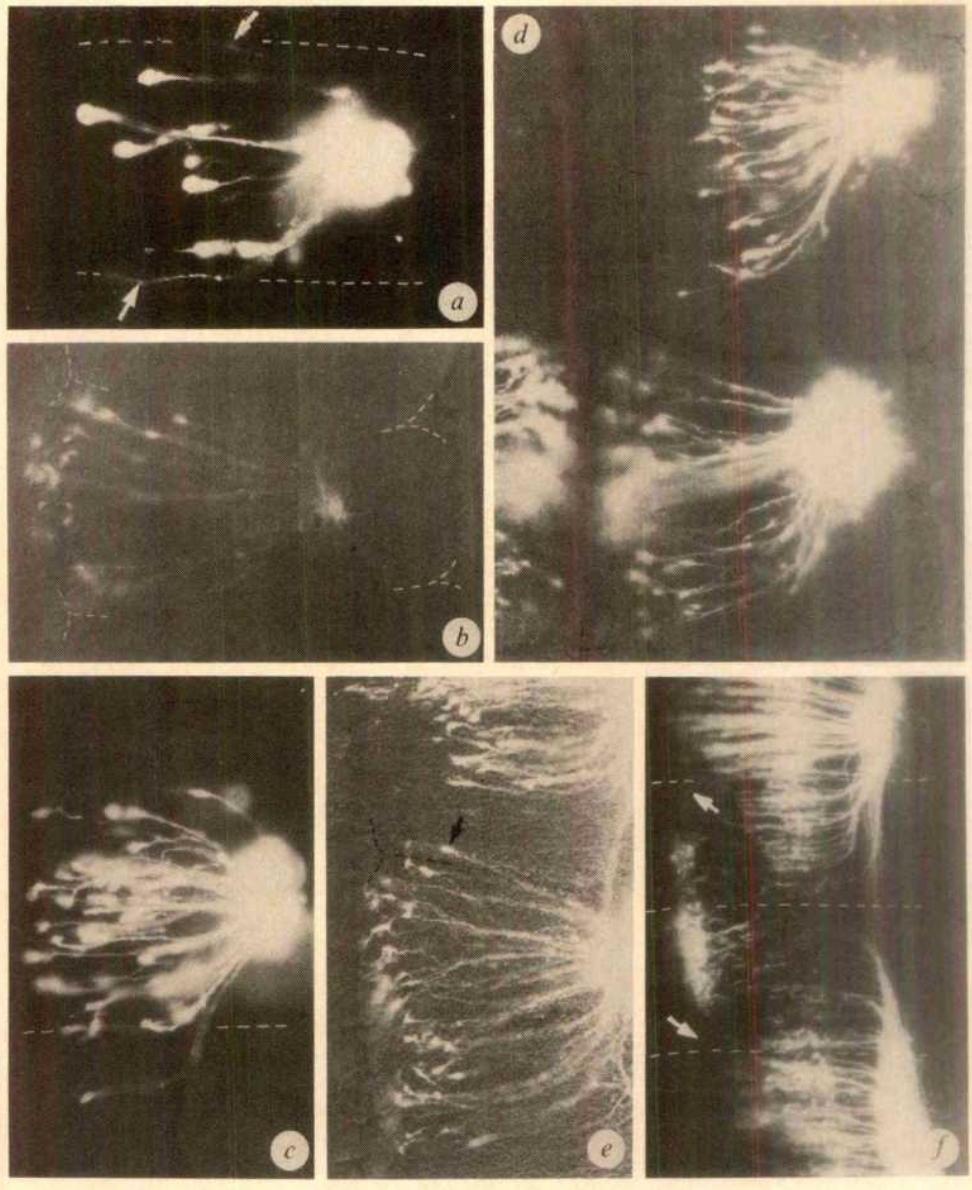

Fig. 3 Fluorescence micrographs of stage 16–19 living whole-mounted hindbrains after injection of cranial nerve roots with DiI. Anterior is to the top, lateral to the right. *a*, Stage 16. Motor neurons of the Vth nerve lie exclusively within r2. The positions of rhombomere boundaries are indicated by dashed lines; axons (arrowed) lie in both the r1/2 and r2/3 boundaries. *b*, Stage 16. Motor neurons of the VIIth nerve lie exclusively within r4. Axons lie in both the r3/4 and r4/5 boundaries; rhombomere boundaries and floor plate–basal plate boundaries are indicated by dashed lines (combined Nomarski/fluorescence optics). *c*, Stage 16+. Motor neurons of the Vth nerve are more numerous in r2, and a single neuron is labelled in r3. The r2/3 boundary is indicated *d*, Stage 17. For both Vth and VIIth nerves, neurons are labelled in two rhombomeres. The r1/2, r2/3, r3/4, r4/5 and r5/6 boundaries are indicated at the lateral edge of the neural epithelium (combined bright field/fluorescence optics). *e*, Stage 17. A single motor neuron (arrowed), labelled by injection of the VIIth root, lies anterior to the r3/4 boundary as indicated (combined Nomarski/fluorescence optics). Such exceptions to the general pattern of motor nuclear origins were observed in nine of 34 stage 17 embryos. *f*, Stage 19. Motor axons of VIth, VIIth and IXth nerves originate from distinct mediolateral as well as A–P positions. The VIth nerve nucleus (labelled by DiO, anterior and posterior limits of DiO labelling indicated by arrows) lies medial to, and is co-extensive with, the r5 component of VII and the r6 component of IX (both labelled with DiI). Sensory axons are labelled in the lateral longitudinal pathway. Boundaries r4/5, r5/6 and r6/7 are indicated.

Methods. The cranial nerve roots were exposed by dissection of the pharyngeal roof and the fluorescent carbocyanine dyes DiI or DiO[36] (Molecular Probes Inc., Junction City, Oregon, 3 mg DiI or DiO in 500 μl dimethyl formamide and 500 μl absolute ethanol) were pressure injected through a 5 μm tip glass micropipette. Embryos were then incubated for 3–4 hours in oxygenated Earle's balanced salt solution at 32 °C in a 95% O_2, 5% CO_2 atmosphere. The hindbrains were dissected from the embryos and viewed immediately under green (DiI) or blue (DiI + DiO) excitation.

numbered rhombomeres; after an early transverse trajectory, axons turn and cross their anteriorly-adjacent boundary to reach their exit point (Fig. 3*d*). Thus, motor axons cross certain boundaries (r2/3 and r4/5), but do not cross others (r1/2, r3/4 and r5/6). All of the boundaries are crossed, however, by axons descending from the midbrain in the lateral longitudinal pathway and by the ascending and descending axons of cranial sensory ganglion neurons. By stage 19, the Vth, VIIth and IXth nerves are related to a column of motor neurons, extending from the r1/2 boundary to a level opposite the first somite, in which the serially-adjacent branchial motor nuclei are segregated at the alternate rhombomere boundaries r3/4 and r5/6 (Fig. 4).

Injection of DiI into the common root of the vagus (X) and accessory (XI) nerves labels cell bodies in a region that is bordered anteriorly by the r6/7 boundary. Rhombomere 7, therefore, contributes neurons to both the IXth and Xth/XIth nerves.

Although the Vth, VIIth and IXth nerve nuclei occupy serially adjacent positions along the A–P axis, the nuclei of the somatic motor system are discontinuous. The generation of these cells conforms, nevertheless, to a segmental pattern (Fig. 4). The IVth nerve nucleus (trochlear) appears at stage 17 in r1, the VIth nerve nucleus (abducens) lies in both r5 and r6 (Fig. 3*f*) and the XIIth nerve nucleus (hypoglossal) lies in r8. It is interesting that the rhombomere pairing of the VIth nerve is out of register by one segmental unit with that of the neighbouring branchial motor nuclei.

Rhombomeres and branchial arches

The branchial nerves V, VII and IX enter the anterior part of their respective branchial arches (first, second and third). In each case, the arch lies ventral to the pair of rhombomeres in which the corresponding motor neuron cell bodies are located; the clefts between arches 1/2 and 2/3 align with the rhombomere

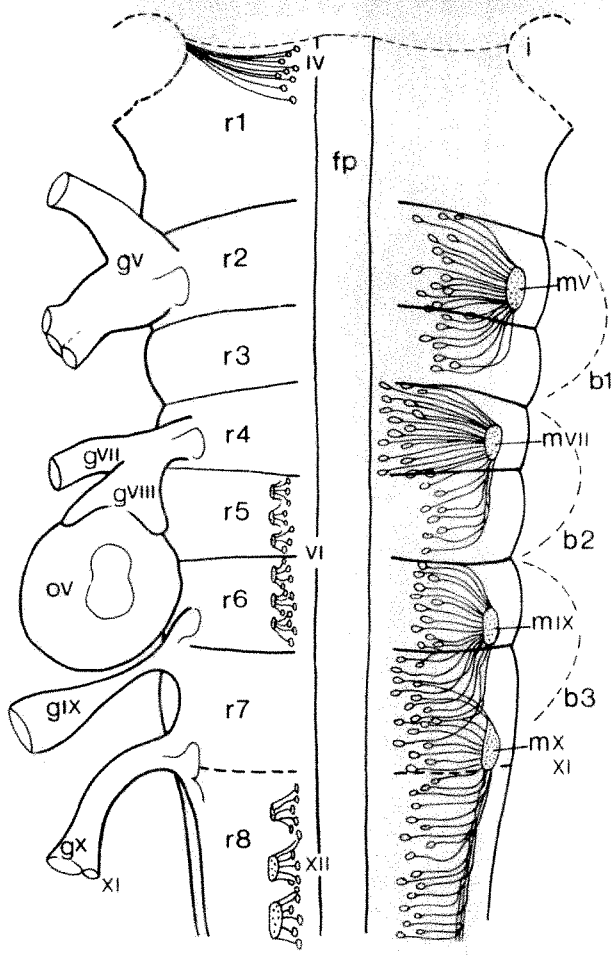

Fig. 4 Schematic diagram of the stage 21 chick embryo hindbrain, based on neurofilament-stained and tracer-injected preparations. The relationship of cranial sensory ganglia (gV–gX), branchial motor nuclei, somatic motor nuclei (IV–XII) and the combined roots of the sensory and branchial motor nerves (mV–mXI) to the rhombomeres (r1–r8) and branchial arches (b1–b3) is shown. ov, otic vesicle; fp, floor plate; i, isthmus/midbrain-hindbrain boundary.

boundaries r3/4 and r5/6 respectively. Thus each of the three principal branchial arches lies in register with the hindbrain segments, in a 1:2 ratio (Fig. 4).

Two-segment repeats

The existence of early segmented neuronal populations and segment boundary-related axons shows that the gross morphological pattern of hindbrain segments finds expression at the cellular level. The process of neurogenesis undergoes a spatiotemporal alternation in successive rhombomeres, involving both the reticular formation and the branchial motor system. Moreover, each branchial motor nucleus occupies a distinct position with respect to the rhombomere boundaries, and is constituted by neurons from two adjacent rhombomeres lying in register with the appropriate branchial arch. These patterns suggest that there are segment specification mechanisms involving two-segment repetition, as has been described for *Drosophila* segmentation[18]. With this in mind, it may be significant that a 'pair-rule'-like pattern of gene expression in the mouse embryo correlates with the alternating pattern of cellular development described here. In E9.5 embryos, the zinc-finger *Krox-20* is expressed in r3 and r5, in each case precisely within the morphological confines of the rhombomere[19].

Segmentation of the neuraxis

The nerve-cord of amphioxus[20], and the hindbrain and spinal cord of fish embryos[21–25] contain segmental arrangements of neurons, but these do not exist in the spinal cords of higher vertebrate embryos[26]. Vertebrate evolution has presumably involved a transition from a segmentally-organised neuromuscular control system for swimming to one more dependent upon long-range integration and control by higher centres. With the attendant loss of intrinsic spinal cord segmentation, the mesoderm has assumed total dominance in trunk segmentation—of skeletal, muscular and peripheral nervous systems[27–29].

The heads of higher vertebrates, however, retain units of construction, the branchial arches, whose derivatives are both anatomically and functionally distinct. Because these require independent as well as integrated control, segmental motor and sensory units are highly conserved. In contrast to the trunk, paraxial mesoderm segmentation in the head[30] is inconsequential, and the lateral plate mesoderm is also unimportant in the patterning process. Rather, it is the neural crest, with its rhombomeric origins, which is responsible for patterning the skeletal and muscular components of each branchial arch[31,32]. Construction of the head may therefore depend fundamentally on the early segmentation of the cranial neuroectoderm.

We thank Vanessa Harrison, Jonathan Carlile and Ken Brady for technical assistance, Peter Hollenbeck, Tom Jessell, Vance Lemmon and Janet Winter for the gift of antibodies, and Jim Cohen and Rob White for comments on the manuscript. This work was supported by grants from the MRC, the Royal Society and the Wellcome Trust.

Recombination occurs during telomere formation in yeast

Ann F. Pluta & Virginia A. Zakian*

Fred Hutchinson Cancer Research Center, 1124 Columbia Street, Seattle, Washington 98104, USA and University of Washington, Department of Pathology, Seattle, Washington 98195, USA

Short stretches of cloned telomeric sequences are necessary and sufficient for telomere formation in yeast as long as the sequences are present in the same orientation as they are found in vivo. *During telomere formation, DNA termini usually undergo* RAD52*-independent recombination with other DNA termini as would be predicted by models of recombination-mediated telomere replication.*

TELOMERES, the physical ends of eukaryotic chromosomes, are essential for the stable maintenance and complete duplication of linear chromosomes. The molecular ends of chromosomes from single-celled organisms to humans bear simple repeats with a defined orientation (C-A rich strand running 5′ to 3′ from the end towards the interior of the DNA molecule), most of which fit the consensus $C_{1-8}(A/T)_{1-4}$ (refs 1-3). The CA-rich strand usually contains nicks and the GT-rich strand extends into a unique terminal structure[1]. Telomere function is also conserved: natural DNA termini from the ciliated protozoans *Tetrahymena* and *Oxytricha* (which bear, respectively, C_4A_2 and C_4A_4 repeats) support the stable maintenance of linear plasmids in *Saccharomyces cerevisiae*[4-6]. In so doing, the ciliate termini are modified by addition of yeast telomeric $C_{1-3}A$ repeats[6-8].

The mechanism for replication of eukaryotic chromosomal termini is unknown. Recombination-dependent replication models[9-14] (Fig. 1) are attractive because they can account for a number of unusual properties of telomeres, such as their ability to grow and shrink[15-18] and the presence of terminal repeats and single-strand nicks, both of which would promote telomere-telomere recombination. But it is difficult to obtain support for recombination-dependent telomere replication because normally there would be no detectable consequence of terminus-terminus recombination because it involves the exchange of identical sequences located on all telomeres. An alternative model, non-templated DNA replication, became appealing with the discovery of telomerase in *Tetrahymena*[19], a ribonucleoprotein capable of extending the 3′ end of the GT-rich strand of different telomeric sequences by the addition of G_4T_2 repeats. The modification of ciliate DNA termini in yeast may also occur via such an activity.

We have determined the DNA requirements for formation of new telomeres in yeast. Our results indicate that 28 base pairs (bp) of cloned telomeric repeats, in the natural orientation and in the absence of any special terminal structure or additional sequences, are sufficient to act as a substrate for the addition of yeast $C_{1-3}A$ repeats. We have also been able to detect recombination between DNA termini, a result consistent with models of recombination-mediated telomere replication.

Cloned telomeric repeats

Linear plasmids were constructed *in vitro* and introduced into yeast by transformation. Each of the *in vitro* constructed plasmids is chimaeric in the sense that its two ends are different. The test end, whose ability to support telomere formation is assayed, carries cloned C_4A_4 repeats, the length and orientation of which are varied in individual experiments. Linear plasmids are named according to the number and orientation of test end sequences, for example YLp112CA contains 112 bp of test end sequences oriented such that the C_4A_4-strand proceeds 5′→3′ from the end to the interior of the plasmid, and YLp28GT contains 28 bp of test-end sequences oriented such that the G_4T_4-strand proceeds 5′→3′ from the end to the interior of the plasmid. The other end of the chimaeric plasmids, referred to as the control end, is a terminal restriction fragment from the extrachromosomal ribosomal DNA of *Tetrahymena* (Fig. 2*b*) that carries ~300 bp of C_4A_2 repeats and efficiently promotes telomere formation in yeast[4,5]. Because the *Tetrahymena* fragments are derived from native rDNA, they, unlike the test end, have all of the *in vivo* modifications, such as terminal foldback structures and single-strand interruptions.

Our data lead to a number of conclusions about the molecular requirements for telomere formation (Table 1). First, a test end consisting of 112 bp of telomeric sequences oriented such that the CA-rich strand proceeds 5′→3′ from the end of the molecule, is sufficient to allow the maintenance of a plasmid as a linear DNA molecule in yeast. This result is also observed when the test end carries as few as 28 bp of telomeric sequence although the percentage of transformants containing linear plasmids decreases as the length of the tract of telomeric repeats on the test end gets shorter. In contrast, test termini with 16, 10, 4 or 0 bp of telomeric sequences or termini with repeats in the wrong orientation do not support telomere formation at detectable frequencies.

'Transfer' of terminal sequences

The structure of many linear plasmids of the correct size obtained with constructs containing 28 to 112 bp of test-end sequences was examined by restriction enzyme digestion and Southern hybridization using probes specific for both plasmid termini. For example, DNA from five independent yeast transformants produced after transformation with YLp112CA was digested with *Pvu*II which cuts once in the vector portion of the plasmid to produce two fragments (Fig. 3*a*), a 2.9-kilobase (kb) fragment containing the test end, and a 7.2-kb fragment containing the control end (before addition of $C_{1-3}A$ sequences at each end). One Southern blot of the digested DNAs was probed with $(G_4T_4)_{4.5}$ which detects test-end sequences (Fig. 3*b*). As predicted, DNA from transformants containing linear plasmids (lanes 2-6) displayed hybridization to a heterogeneous band with an average size of 3.2 kb. The test end probe displayed no cross-hybridization with either yeast or vector sequences (lane 1), or with cloned C_4A_2 repeats (lane 7). The same digestion mixtures run on an identical gel were hybridized to the $(G_4T_2)_7$ probe, which detects the C_4A_2 repeats at the control end of the plasmid (Fig. 3*c*). DNA from all transformants showed the expected band of hybridization at 8.3 kb. Again, no cross-hybridization between the $(G_4T_2)_7$ probe and either yeast or vector sequences (lane 1), or cloned C_4A_4 repeats (lane 8) was

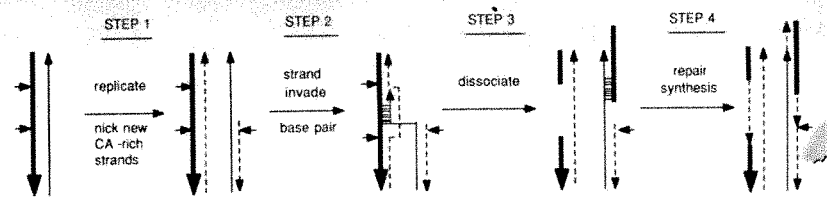

Fig. 1 Recombination model for telomere replication (redrawn from ref. 14). Each strand of a DNA duplex is represented by a line: thin lines indicate the GT-rich strand, thick lines indicate the CA-rich strand, dashed lines indicate newly replicated DNA. The 3′end of each strand is indicated by an arrowhead. Nicks in CA-rich strands are indicated by horizontal arrows. Step 1: after DNA replication and subsequent removal of the RNA primer, a 5′ terminal gap is produced on each duplex. (For simplicity, only one such gap on a pair of sister chromatids is shown.) Specific nicks are made on the newly-replicated CA-rich strand. Step 2: the free 3′ tail (thin line) invades the sister duplex, base-pairs in an out-of-register configuration with the complementary strand (thick line), displacing its complementary strand (dashed line). Step 3: dissociation of the newly base-paired region is facilitated by nicks present on the CA-rich strand of the donor (thick line). Step 4: the resulting internal gap and terminal 3′ gap on each duplex is filled by repair synthesis (dashed line) and remaining nicks are sealed by DNA ligase. Replication by this mechanism results in two fully replicated duplex molecules, one of which (duplex on the right) is longer (thereby providing a molecular explanation for how telomeres can increase in length) and has sequence information obtained from the thick duplex on the left.

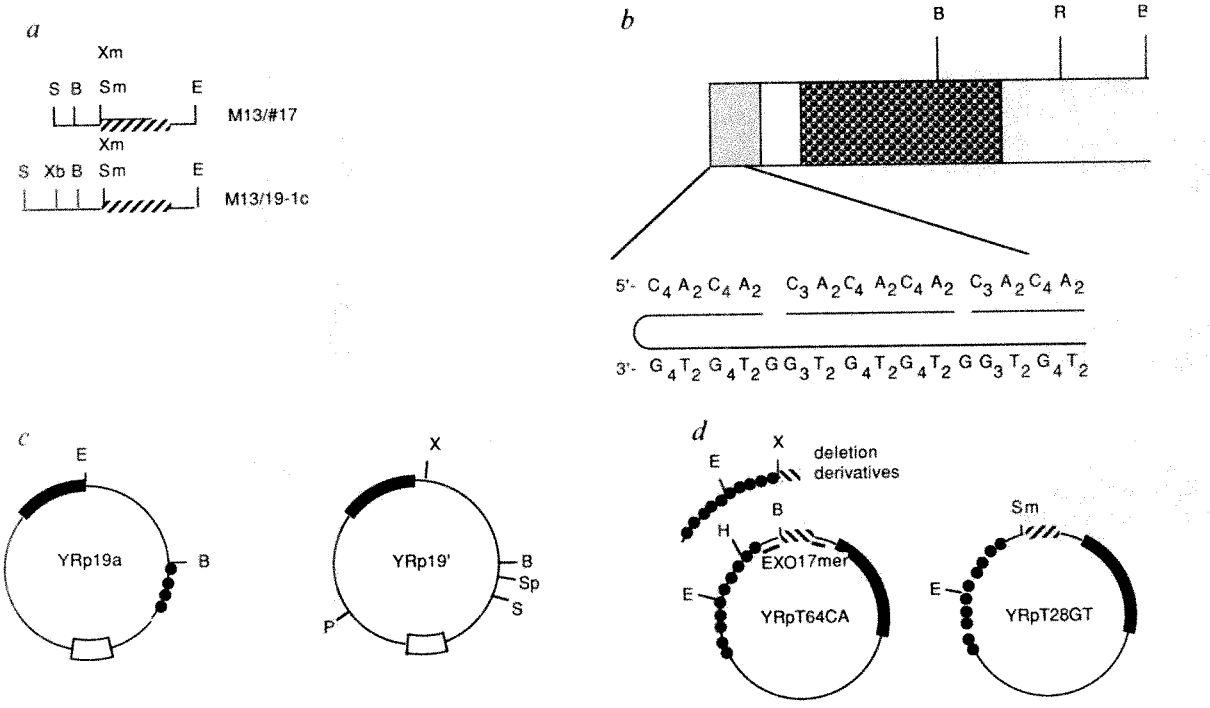

Fig. 2 DNA Structures. *a*, Cloned progenitors of test ends. The ~130-bp *Sal*I–*Eco*RI restriction fragments from either M13/#17 (mp9) or M13/19-1c (mp19) were used to create test ends of various lengths and orientations. Both plasmids contain 112 bp of 5′$(C_4A_4)_n$3′, indicated by the diagonally-striped box, where *n* was determined to be 14 by DNA sequence analysis. *b*, Control end. The terminal *Bam*HI (B) and *Eco*RI (R) restriction fragments of *Tetrahymena* rDNA were used as control end sequences on the chimaeric linear plasmids. The end of each consists of ~300 bp of C_4A_2. Adjacent unique sequences are indicated by the spotted box. Ribosomal DNA was isolated from *Tetrahymena thermophila* strain C3V (ref. 30). *c*, Vectors used to create YLp112CA, YLp112GTS and YLp112GTX. YR19′ is a 9.1-kb plasmid that contains *TRP1ARS1* (solid box) and *URA3* (open box). It was derived from YCp19 (ref. 31) by removal of the 1.5-kb *Xho*I fragment containing *CEN4*. YLp112CA was constructed by ligating test end sequences derived from M13/19-1c to the *Sal*I site and control-end sequences to the *Bam*HI site. YRp19a, which was used to construct YLp112GTS and YLp112GTX, is an 11.2-kb derivative of YRp19′ in which the 187-bp *Bam*HI–*Sph*I portion was replaced with a 2.3-kb *Bam* HI–*Sph*I fragment of λ DNA (indicated by solid circles). *d*, Vectors used to construct YLps with test ends of 64 or fewer base pairs. The important feature of these vectors is that they contain test-end sequences in either of two orientations which are exposed as a free DNA terminus upon digestion with *Bam*HI (YRpT64CA), *Xho*I (deletion derivatives of YRpT64CA) or *Sma*I (YRpT28GT), and a single *Eco*RI site for ligation of control-end sequences. *Symbols*: solid box, *TRP1ARS1*; open box, *URA3*; solid circles, λ DNA; ////, 5′$(G_4T_4)_n$3′; \\\\, 5′$(C_4A_4)_n$3′; ————, pBR322 or pUC. B, *Bam*HI; Bg, *Bgl*II; E, *Eco*RI; H, *Hpa*I; Hd, *Hin*dIII; P, *Pvu*II; S, *Sal*I; Sm, *Sma*I; *Sp*, *Sph*I; X, *Xho*I; Xb, *Xba*I; Xm, *Xma*I.

Methods. *a*, M13/#17 was constructed by D. Gottschling by annealing two oligonucleotides, 5′-$C_4A_4C_4A_4$-3′ and 5′-$G_4T_4G_4T_4$-3′, such that out-of-register concatemers with four-base overhangs were produced. The unfractionated product was treated with T4 DNA polymerase to create blunt ends, and inserted into the *Sma*I site of M13mp9 such that the (+) strand of the phage DNA is the G_4T_4 strand. Plasmid 19-1c is the *Eco*RI–*Bam*HI fragment of M13/#17 inserted into *Eco*RI–*Bam*HI-digested M13mp19. Sequencing by the dideoxy chain termination method on alkaline-denatured[28] supercoiled plasmid templates was essentially as described[29] except that elongations were performed at 45 °C. *b–d*, For plasmid YRpT64CA, 130-bp *Sma*I–*Eco*RI fragment containing ~14 C_4A_4 repeats was isolated from M13/#17, treated with 5U S1 nuclease for 30 minutes at room temperature, and inserted into the *Sma*I site of pUC19. For plasmid YRpT28GT, the *Bam*HI–*Eco*RI fragment of M13/#17 was inserted into *Bam*HI–*Eco*RI-digested pUC19. Subsequent steps of the constructions were identical for the two plasmids. The *Eco*RI site in the polylinker was destroyed by treatment of *Eco*RI-digested DNA with T4 DNA polymerase and dNTPs to create blunt ends, followed by self-ligation. Termini of the 1.45-kb *Eco*RI fragment containing *TRP1ARS1* were rendered flush by treatment with T4 DNA polymerase, and inserted into the T4 polymerase-treated *Nar*I site of each plasmid. A 3-kb *Sph*I fragment of λDNA, which contains a single *Eco*RI site, was inserted at the *Sph*I site in the polylinker of each plasmid. The resulting plasmids, YRpT64CA and YRpT28GT, are ~7.1 kb in length, contain unique *Bam*HI and *Eco*RI sites, and retain 64 bp of 5′(C_4A_4)3′ and 28 bp of 5′(G_4T_4)3′, respectively. Position of oligonucleotides (EXO and 17-mer) used for hybridization probes and sequencing primers are indicated. Deletion derivatives of YRpT64CA were constructed by limited digestion with Exonuclease III (ref. 32) from the single *Hpa*I site in the λ DNA. Blunt ends were created by treatment with T4DNA polymerase and dNTPs. The DNAs were then ligated to *Xho*I linkers, and following *Xho*I digestion, gel purification and self-ligation, were used to transform *E. coli*. The resulting transformants were subjected to three successive screens to identify plasmids with fewer than 64 bp of C_4A_4 as well as the necessary restriction sites for construction of chimaeric linear plasmids: (1) sequential colony hybridizations[33] with end-labelled EXO III probe and with the M13 17-mer sequencing primer, (2) DNA was prepared from colonies that hybridized to the 17-mer but not the EXO III oligonucleotide probe and analysed for the presence of both the *Xho*I and *Eco*RI sites, and (3) plasmids containing both an *Xho*I and *Eco*RI recognition site were sequenced to determine the number of C_4A_4 repeats.

bserved.

Some unexpected results were obtained with both the control-nd and the test-end probes. In DNA from four of the five ransformants (Fig. 3*c*, lanes 3–6), the control-end probe also ybridized to a heterogeneous fragment with an average size of 2 kb, the same size fragment detected when the DNA samples ere hybridized with the $(G_4T_4)_{4.5}$ probe (Fig. 3*b*). These results idicate that the test end on four of the five plasmids contains $_4A_2$ repeats in addition to the expected C_4A_4 repeats. The ossibility that these results are due to ligation of the *Tetrahymena* terminus to both ends of the plasmid was eliminated by emonstrating that only the C_4A_2 repeats and none of the djacent unique DNA in the *Tetrahymena* fragment hybridizes o the 3.2-kb fragment (Fig. 3*d*). In addition to the unexpected esults with the control-end probe, in DNA from one of the ransformants, the test-end probe unexpectedly displayed ybridization to a fragment of 8.3 kb (Fig. 3*b*, lane 6) indicating hat the control end of this plasmid bears C_4A_4 as well as C_4A_2 epeats. Transfer of control-end sequences to the test end has een observed for the majority (90 per cent) of correct sized near plasmids regardless of the length of the test end (Table). On 20 per cent of the plasmids examined, C_4A_4 repeats were etected on the end of the plasmid bearing the control terminus.

The terminal location of the telomeric sequences was estab-ished by monitoring their disappearance after digestion with he exonuclease BAL-31. BAL-31 digestion was carried out on otal DNA from a strain carrying YLp112CA-5, a linear plasmid n which C_4A_2 sequences were detected on both the control and est ends of the plasmid (Fig. 3, lane 5). After BAL-31 digestion, he DNA was digested with *Xho*I which produces a 3.1-kb ragment containing the control end and a 7.0-kb fragment ontaining the test end (before $C_{1-3}A$ addition). *Xho*I digestion f yeast chromosomal DNA produces a heterogeneous fragment f ~1.3 kb derived from Y′-bearing telomeres, as well as many ther telomeric and non-telomeric fragments[7]. Figure 4 shows hat the transferred C_4A_2 repeats, like the other telomeric equences, are BAL-31 sensitive and therefore close to the lasmid end.

Total yeast DNA from a strain containing YLp112CA-5 (Fig. , lane 5) was digested with *Bgl*II (which removes the control nd, Fig. 1*c*), self-ligated and used to transform *Escherichia coli*. subclone carrying the test end of YLp112CA-5 was digested ith *Bam*HI and then for increasing amounts of time with AL-31 to determine the order of the telomeric sequences rela-ve to the end of the plasmid (Fig. 5). Because the relevant *Bam*HI site in YLp112CA-5 is in vector DNA immediately djacent to the test end, those sequences closest to the physical nd of YLp112CA-5 should be the most resistant to the exo-uclease. This analysis demonstrates that $C_{1-3}A$ sequences are he most distal sequences on YLp112CA-5 followed by the ransferred C_4A_2 repeats and then the C_4A_4 repeats, a result onfirmed by DNA sequencing (S.-S. Wang, unpublished data). herefore, transfer of control-end sequences probably occurs efore $C_{1-3}A$ addition.

What is the mechanism by which the terminal sequences are ransferred between DNA termini? The transfer is not a ligation rtefact because it involves only terminal CA-rich sequences, ot the adjacent unique sequence DNA (Figs 3, 4). Transfer annot be the result of the asymmetric resolution of a circular ntermediate formed by end-to-end fusion of the starting plasmid n yeast to give a circular plasmid with chimaeric inverted epeats[20]: asymmetric resolution of such a plasmid produces a NA terminus carrying terminal sequences in the reverse rientation, which cannot function as a telomere in yeast (Table). Finally, if telomerase exists in yeast it would be expected to dd $C_{1-3}A$ repeats, but not non-yeast telomeric repeats[19]. Therefore, the most reasonable interpretation of these data is that uring telomere formation, DNA termini usually undergo ecombination.

Table 1 Formation of linear plasmids

Plasmid	Per cent correct	Number analysed	Number transferred
YLp112CA	56	48 (13)	12/15
YLp64CA	35	20 (11)	7/7
YLp48CA	22	23 (3)	5/5
YLp40CA	9	35 (12)	4/4
YLp28CA	6	64 (42)	3/3
YLp16CA	0	148*	NA
YLp10CA	0	275*	NA
YLp4CA	0	264*	NA
YLp0CA	0	94	NA
YLp112GTX	0	54	NA
YLp112GTS	0	81*	NA
YLp28GT	0	218†	NA
YLp112CA/*rad52*	50	8† (100)	3/4

Each yeast linear plasmid (YLp) is defined by the number of base pairs and the orientation of the test-end sequences it carries (see text). The terminal structure of the test end is the DNA terminus generated by digestion with the following restriction enzymes: *Eco*RI (YLp112CA), *Bam*HI (YLp64CA), *Xma*I (YLp112GTX), *Sma*I (YLp112GTS, YLp28GT), *Xho*I (all other YLps). YLp112CA was constructed by simultaneous ligation of the 8.8-kb gel-purified vector (*Bam*HI–*Sal*I digested YRp19′) with the gel-purified 130-bp *Eco*RI–*Sal*I fragment isolated from 19-1c containing $(C_4A_4/G_4T_4)_{14}$ and with the gel-purified 1.3-kb terminal *Bam*HI fragment from *Tetrahymena* rDNA (see Fig. 2). All other YLp(n)CA plasmids were constructed by double digestion of YRpT64CA (or deletion derivatives thereof) with *Eco*RI and with the enzyme indicated above to expose test end sequences. The resulting fragment (~5.8 kb) was gel-isolated and ligated to gel-isolated 2.6-kb terminal *Eco*RI fragment from *Tetrahymena* rDNA. In most experiments, ligation mixes were introduced into strain 34c (*MATa met2, his3∇-1, leu2-3, leu2-112, tripl-289, ura3-52, cir*^{0}) by lithium acetate transformation. For the *RAD52* experiments, DNA was introduced into strain XS95-6C (*MATα, rad52-1, ura3-52, trpl, his3∇-1, leu2-112, 3*; from D. Schild) by spheroplast transformation. All of the *rad52* transformants containing linear plasmids retained hypersensitivity to X irradiation. Total undigested DNA isolated from transformants was analysed for the presence of plasmid sequences by Southern hybridization with ^{32}P-labelled pBR322. The percentage of transformants analysed which contained linear plasmids of the predicted size and structure is indicated by per cent correct. Other classes of transformants were those containing circular plasmids, no plasmids (that is gene conversion), or plasmids larger than 23.7 kb most of which did not hybridize to the test-end probe. When control termini are ligated to both ends of the vector, the per cent correct is similar to results obtained with YLp112CA. Unless otherwise noted, values reflect data collected from a single experiment. For constructs producing no linear plasmids of the correct size, nearly every transformant was analysed. For those constructs which produced linear plasmids of the correct size, the percentage of the total number of transformants which were analysed is indicated in parentheses (under number analysed). The number of linears of correct size that displayed transfer of terminal sequences over the number of linears of correct size examined is presented (number transferred). NA, not applicable.

* Data pooled from two independent experiments.

† Data pooled from three independent experiments.

The *RAD52* gene product is required for the majority of mitotic recombination events, including chromosome 'healing' by gene conversion[21]. The *RAD52* product is not required for sister chromatid exchange[22,23], nor for the addition of $C_{1-3}A$ repeats on ciliate DNA termini[21,24]. When the linear plasmid YLp112CA was introduced into a *rad52* strain, three of the four linears obtained exhibited transfer of C_4A_2 repeats to the test end (Table 1). Therefore, this telomere–telomere recombination must occur via recombination between the very ends of DNA molecules rather than by exchange of internal CA-sequences that would involve *RAD52*-dependent double-strand break repair.

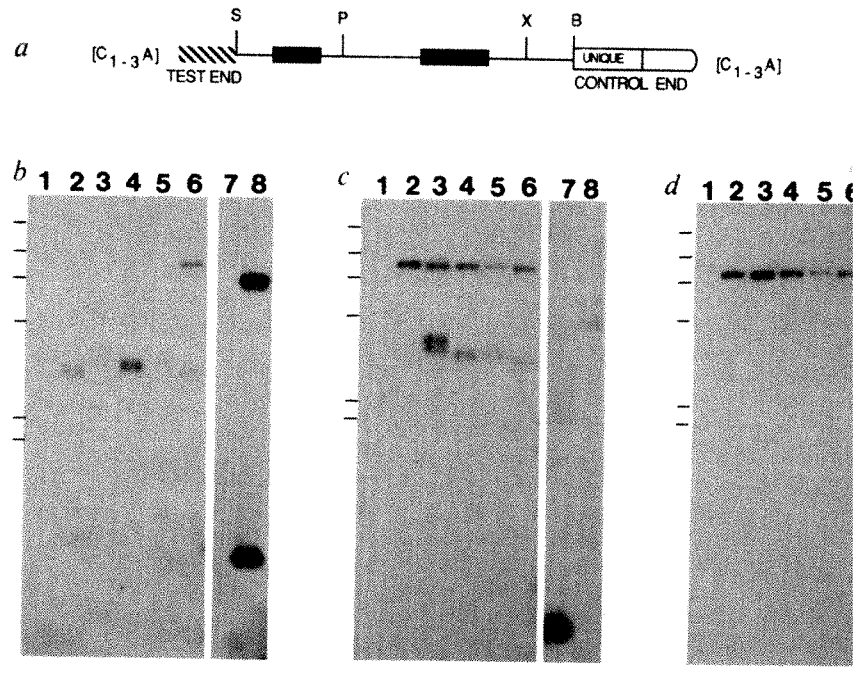

Fig. 3 Transfer of terminal sequences on a chimaeric linear plasmid. *a*, Predicted structure of YLp112CA. The linear plasmid has a predicted size of ~10 kb and a single *Pvu*II site which, when cut, produces a 2.9 kb fragment containing the test end and a 7.2 kb fragment containing the control end (before $C_{1-3}A$ addition, which is expected to add ~500 bp per terminus). *b–d* *Pvu*II digestions of total DNA isolated from transformants containing linear and circular plasmids. *b*, Hybridization with $(G_4T_4)_{4.5}$, the test-end probe, and *c*, $(G_4T_2)_7$, the control-end probe. *d*, The probe was removed from the blot shown in *c* and the filter was rehybridized with the unique sequence probe for the control end. Lanes 1–6 contain, respectively, total DNA from yeast transformants carrying YRp19′, YLp112CA-1, YLp112CA-3, YLp112CA-4, YLp112CA-5 and YLp112CA-6. Controls are lane 7, pTC5 (obtained from A. Murray), digested with *Xho*I and *Bam*HI to give a fragment (~300 bp) containing $(C_4A_2)_{50}$; lane 8, p0f1 (cloned *Oxytricha* macronuclear rDNA (ref. 34)) digested with *Pst*I to give three fragments, two of which (a 6.7-kb fragment and a 0.9-kb fragment) contain 30–35 bp (C_4A_4). Size markers indicated by horizontal lines are *Hin*dIII-digested lambda DNA.

Methods. Total yeast DNA was isolated[35], fractionated on two identical but separate gels and transferred to nitrocellulose. Hybridizations using end-labelled oligonucleotide probes were performed at 42 °C in 50% formamide, 5 × SSC, 1 × Denhardts[33], 1 mg ml^{-1} heat-denatured herring sperm DNA and 10% dextran sulphate for 8–15 hours. Hybridization conditions using nick-translated probes are described[36]. Nitrocellulose filters were washed at room temperature for 30 min in 5 × SSC, followed by a 50 °C wash for 1 h in 5 × SSC, 0.1% SDS. The 1,050-bp *Hin*dIII fragment isolated from pRP7 (ref. 37) which contains the non-coding region near the end of the *Tetrahymena* rDNA molecule was subcloned into M13mp19 and used as the unique sequence probe for the control end.

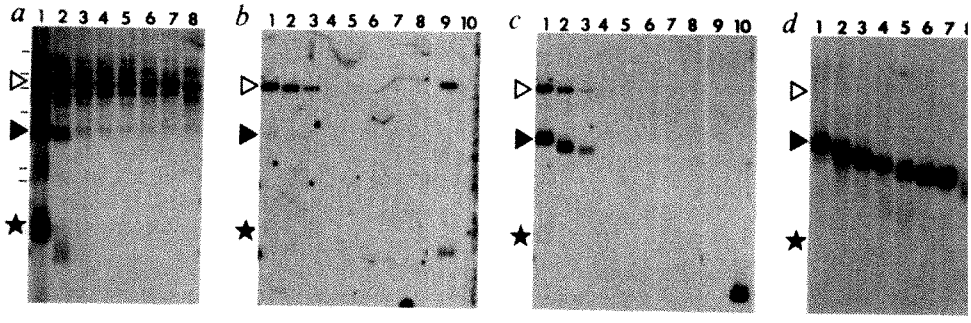

Fig. 4 Transferred terminal sequences are sensitive to BAL-31 digestion. Total DNA from a strain produced by transformation with the linear plasmid YLp112CA-5 (Fig. 3, lane 5), was treated with BAL-31. Probes are $C_{1-3}A$ (*a*); $(G_4T_4)_{4.5}$ (*b*); $(G_4T_2)_7$ (*c*) and control-end unique sequence (*d*). Lanes 1–8 contain, respectively, DNA removed after 0, 10, 20, 30, 40, 50, 60 and 120 minutes of BAL-31 digestion; lane 9, *Pst*I-digested p0f1 (contains C_4A_4 sequences); lane 10, *Xho*I-*Bam*HI digested pTEC1.6 which yields a fragment of ~700 bp containing $(C_4A_2)_{50}$. Size markers indicated by horizontal lines are *Hin*dIII-digested lambda DNA. The open arrow points to fragments carrying the test end, the closed arrow to fragments carrying the control end, and the star to terminal fragments from Y′ bearing chromosomal DNA molecules.

Methods. Samples were taken over a 2-h period, digested with *Xho*I, subjected to electrophoresis and sequential Southern hybridization. The $C_{1-3}A$ probe was prepared by gel-isolation of a 125 bp fragment which contains 81 bp of cloned $C_{1-3}A$ sequences derived from a yeast telomere[8].

Discussion

Using linear plasmids in which each terminus is marked with a different telomeric sequence, we have shown that cloned telomeric sequences 28 bp or longer support telomere formation in yeast. Although termini as short as 28 bp can support telomere formation, the number of correct sized linear plasmids recovered is small (≤9 per cent) with test ends shorter than 48 bp (Table 1). During formation of new telomeres, telomeric sequences usually undergo recombination by a process that does not require the *RAD52* gene product. Thus, although C_4A_4 and C_4A_2 repeats share only limited homology, these sequences are presumably capable of base pairing *in vivo*, possibly facilitated by the ability of these sequences to adopt unusual DNA conformations[25] and/or by a RecA-like protein that promotes strand exchange[26]. Precedent for base pairing of telomeric repeat sequences with nonhomologous but related DNA sequences is provided by the ability of poly(dGT) to hybridize under high stringency conditions to yeast $C_{1-3}A$ sequences[6,7].

What is the *in vivo* role for this telomere-telomere recombination? Recombination could be a consequence of repair or maintenance processes although its *RAD52*-independence argues against this interpretation. Alternatively, the telomere-telomere recombination may be linked to telomere formation in which case it might also be the mechanism by which $C_{1-3}A$ repeats are added to ciliate termini. Telomere recombination can be visualized in terms of a model for telomere replication[14] (Fig. 1): after replication the 3′ overhang produced by primer excision at the end of the chromosome is able to strand invade and base pair with a complementary region on another strand. In our system, this recombination could occur between the two ends of the same plasmid or between termini on different DNA molecules of these multicopy plasmids. Subsequent strand dissociation is

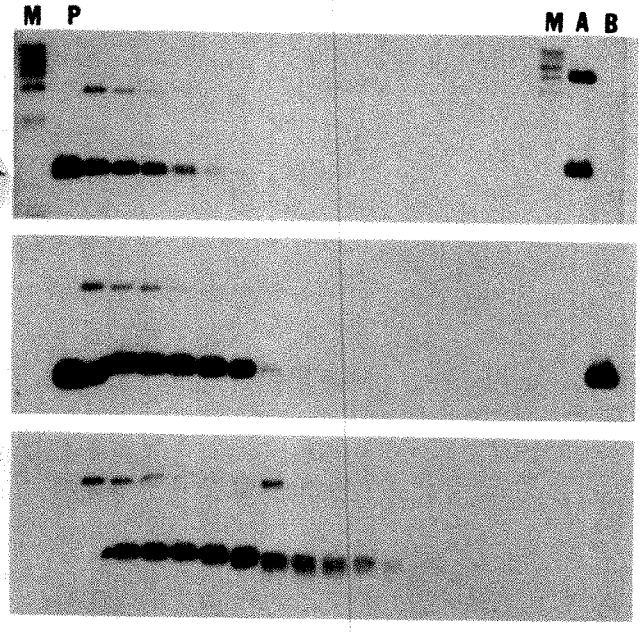

Fig. 5 BAL-31 digestion of cloned telomere. A recombinant DNA plasmid containing the test end of the yeast propagated plasmid YLp112CA-5 (Fig. 3, lane 5) was digested with BAL-31 to determine the order of the telomeric sequences. Southern blots were probed successively with: $(G_4T_4)_{4-5}$, *a*; $(G_4T_2)_7$, *b*; and $C_{1-3}A$, *c*. The lanes contain: M, *Hin*dIII-digested λ DNA; P, *Hin*dIII-*Bam*HI digested tc-0-6; A, *Pst*I-digested p0f1 DNA (C_4A_4), and B, *Xho*I-*Bam*HI digested pTEC1.6 DNA containing $(C_4A_2)_{50}$. The rest of the lanes from left to right contain samples digested for increasing amounts of time with BAL-31.

Methods. Total DNA from yeast containing YLp112CA-5 was digested with *Bgl*II, treated with T4 DNA polymerase in the presence of dNTPs and self-ligated. Digestion of YLp112CA with *Bgl*II removes the control end terminus (Fig. 2*c*), and self-ligation produces a plasmid (called tc-0-6) containing test end sequences. Plasmid tc-0-6 was first digested with *Bam*HI (the *Bam*HI site is derived from the poly-linker of M13/19-1C and is <10 bp from the C_4A_4 repeats) and then digested with BAL-31. Aliquots were removed at 5-min intervals during the first 0–30 minutes of digestion and then at 2-min intervals thereafter. Samples were digested with *Hin*dIII to release a fragment of ~1kb containing the sequences from the test-end of YLp112CA, and subjected to electrophoresis. A portion of the nitrocellulose (containing *Hin*dII-*Bam*HI digested tc-0-6 and the zero time point) was lost during washing from panel *c*. In each plasmid lane, the upper band is partially digested plasmid.

facilitated by specific nicks in the CA-strand. Any remaining gaps are closed by repair synthesis. Recombination by this mechanism is expected to be *RAD52*-independent because it does not involve repair of double-strand breaks. If recombination is necessary for telomere formation, the frequency of telomere formation is expected to be related to the length of the recombining end. Consistent with this, as the test end is decreased in size, the efficiency of telomere formation drops (Table 1). However, the fraction of plasmids of the correct size on which we detect transfer of terminal sequences is independent of the length of the test end (Table 1). Because nicks are concentrated in the CA-strand[1], the orientation requirement can also be explained by a recombination model. With telomere sequences in the reverse orientation, the invading strand is now the CA-strand instead of the GT-strand, and dissociation of the base-paired segment would require additional enzyme activities. The fact that nicks are concentrated in the CA-strand could also explain why we more often detect transfer of C_4A_2 repeats to the test end: the test end lacks single-strand nicks and therefore is expected to be an inefficient donor compared to the control end. Alternatively, the shorter test end may be an inefficient donor of terminal sequences because it (1) offers a smaller target for base pairing with the invading strand or (2) the amount transferred from this shorter tract is usually too little to be detected by hybridization.

We have demonstrated that during telomere formation in yeast, DNA termini often undergo recombination with other DNA termini. This system is the first in which there is a detectable consequence of recombination between the very ends of DNA molecules that can be distinguished from the consequences predicted by telomerase-mediated DNA replication. The question remains as to the *in vivo* role, if any, of telomere-telomere recombination. For example, the role of recombination among the terminal repeats may be to maintain their homogeneity[27]. Alternatively, recombination might be involved in telomere replication, either in concert with telomerase or not. The ultimate test of these possibilities awaits the identification and characterization of mutants defective in maintenance of linear chromosomes. If recombination is important for telomere replication, some of these mutations are likely to be in genes encoding recA-like proteins, which like the T4 uvsX protein[11], promote synapsis between terminal sequences.

Search for strange matter by Rutherford backscattering

According to a number of suggestions, stable strange matter could exist in the form of supermassive nuclei (or 'strange nuggets')[1,2]. In contrast to ordinary nuclei, which contain only 'up' and 'down' quarks, a piece of strange matter should comprise a mixture of 'up', 'down' and 'strange' quarks in roughly equal proportions. Small amounts of strange matter could have survived from the early stages of the Universe[1]. Alternatively, strange matter might reach the Earth as a flux of strange nuggets produced in collisions of neutron stars[3]. Limits to the cosmic flux of strange nuggets with masses in the range from 10^{-4} to 250 g have been obtained in a search for light produced by the nuggets in the upper atmosphere[4]. Here we report the results of a search for supermassive nuclei by using Rutherford backscattering of heavy ions. The method is sensitive to a broad range of masses extending to those that exceed the projectile mass by several orders of magnitude. Upper limits for the abundance of strange nuggets with masses $A \approx 4 \times 10^2$ to 10^7 AMU relative to the number of nucleons were found to be in the range 10^{-10} to 10^{-14}.

To set a useful sensitivity limit for experiments designed to search for strange matter, De Rújula and Glashow estimated the maximum concentration of strange nuggets in the Earth's crust[3]. They assume a value of $\sim 10^{-24}$ g cm^{-3} for the local dark matter density of our Galaxy. Assuming that the whole of dark matter consists of strange nuggets, this flux corresponds to an annual Earth infall of strange matter of $\sim 10^9$ g. Over the Earth's 4.6-Gyr history this results in a maximum crustal concentration of 10^{-7} by mass. For the mass range considered in our experiment, $A \approx 4 \times 10^2$ to 10^7, this limit extends from 3×10^{-10} down to 10^{-14} nuggets relative to the number of nucleons. Because nuggets with these masses are already stopped in the Earth's atmosphere[3] they should not be distributed equally over all of the crust but should be concentrated in its upper layer, in which region the local abundance of nuggets may therefore be higher by two to three orders of magnitude.

In our experiments natural samples were irradiated with beams of ^{238}U and ^{208}Pb nuclei provided by the heavy-ion accelerator UNILAC in Darmstadt. The bombarding energy was 1.4 MeV per nucleon; this is far below the Coulomb barrier of nuclei, so that the cross-section for nuclear reactions is negligible[5], and the interaction of nuclei is dominated by elastic scattering. In this case the angle and the velocity of the scattered projectile nucleus are determined by the mass of the target nucleus. In a single scattering event a projectile can be scattered into the backward hemisphere only by a heavier nucleus. Therefore, scattering of ^{238}U or ^{208}Pb through angles of 90°–180° would indicate the presence of more massive and possibly strange nuclei.

Scattered nuclei were detected by a system of twelve low-pressure multi-wire proportional counters[6] (Fig. 1) divided into four identical modules, each of which consisted of one start- and two stop-detectors. The ranges of scattering angles covered by this system are 92°–120° and 127°–170°, with a total solid angle of 1.15 sr.

The identification of detected nuclei is based on the following

§ Present address: Industrie-Automation, D-6108 Gräfenhausen, FRG.

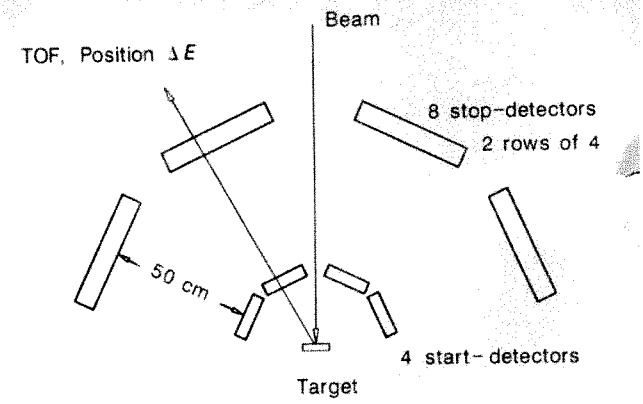

Fig. 1 Schematic diagram of the detection system. Four modules of multi-wire proportional counters are installed symmetrically around the beam axis (top view). Each detector module consists of a single start- and two stop-detectors, placed one above the other.

quantities. The time-of-flight (TOF), or equivalently the velocity of each scattered nucleus is calculated from the time signals of start- and stop-detectors. The specific ionization (ΔE), which depends on the atomic number Z and the velocity v of the nuclei according to $\Delta E \propto (Z/v)^2 \ln(v^2)$, is measured by the stop-detectors, and, by calibrating ΔE against TOF, ΔE therefore characterizes the atomic number of each nucleus (Fig. 2). The trajectory and, in turn, the scattering angle is obtained from the position measurements in the start- and stop-detectors.

A target of ~1–2 mm thickness, prepared from an iron meteorite (Sam's Valley meteorite, Medford, Oregon, 1894), was irradiated with 1.7×10^{14} particles of ^{238}U. Figure 2*a* and *b* shows the two-dimensional spectra, in terms of ΔE as a function of TOF, of particles in the angular regions 92°–120° and 127°–170°, respectively. No data were recorded below $\Delta E \approx 110$ (in relative units) because of an electronic cutoff.

The solid curves in Fig. 2*a*, *b* represent the 2σ range (95.4% probability) of ΔE-TOF values for ^{238}U scattered from a thin uranium target in a calibration experiment. No scattered uranium nuclei were recorded for a TOF below 90 ns. Some uranium nuclei with a TOF greater than 90 ns are seen at 92°–120° (Fig. 2*a*), but no uranium nuclei were recorded at angles exceeding 127° (Fig. 2*b*). This strong decrease in the number of scattered nuclei with angle is typical of multiple scattering, and for this reason the events with TOF > 90 ns were excluded from the analysis. The absence of events between TOF ≈ 30 ns, which corresponds to the initial velocity of uranium nuclei, and 90 ns can be used to estimate limits for the abundance of supermassive nuclei in a certain mass range. The lower limit of this mass range is determined by TOF = 90 ns, which corresponds to backscattering of uranium from nuclei with mass $A \approx 400$ located at the target surface.

A group of scattered nuclei with TOF centred around 70–80 ns, with specific ionization much lower than that for uranium ions of the same velocity, was observed at angles of 92°–120° (Fig. 2*a*). From comparison with the calibration curves, this group was identified as comprising nuclei with $Z \approx 30$, which we thus attribute to iron nuclei. The dashed curve in Fig. 2 shows the loci of iron nuclei as calculated from tabulated energy loss values[7]. As iron is the main component of the meteorite, an observation of scattered iron nuclei is not surprising. Such events can result from rescattering of iron recoil nuclei produced in primary uranium–iron collisions. We emphasize here that the identification of nuclei does not require any knowledge of the underlying scattering process (single or multiple), but is based entirely on the experimental calibration curves of ΔE against TOF.

To calculate upper limits for the abundance of supermassive nuclei with mass A, the Rutherford-scattering cross-section an

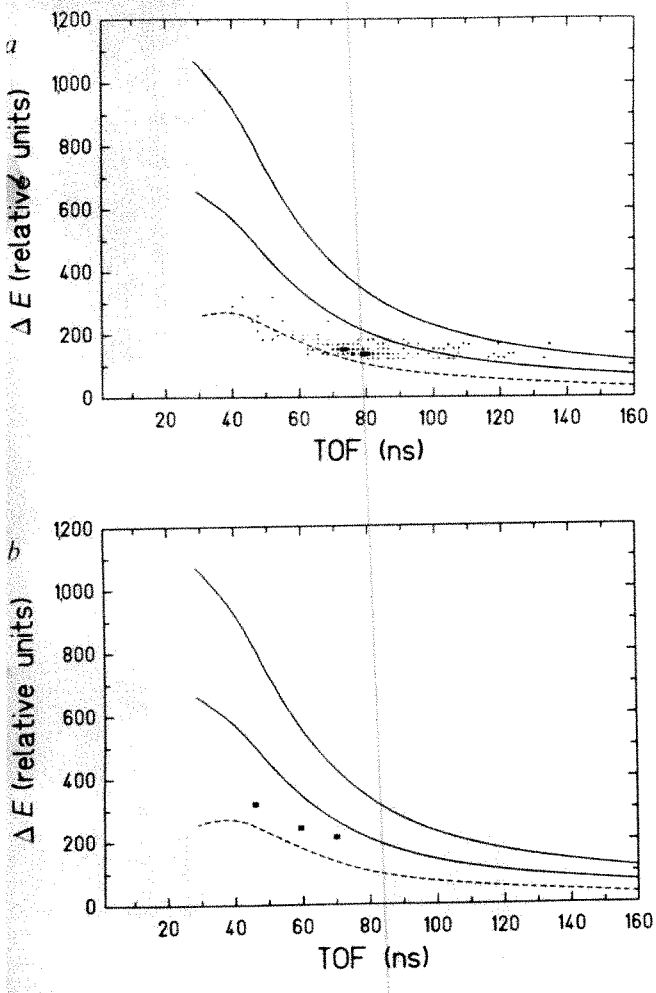

Fig. 2 Two-dimensional spectrum of specific ionization (ΔE) against time-of-flight (TOF) in the angular regions 92°–120° (*a*) and 127°–170° (*b*). The points represent the loci of a total of 245 (*a*) and 3 (*b*) detected particles. No data were recorded below $\Delta E \approx 110$. The initial projectile velocity corresponds to a TOF of 30 ns. The dashed line indicates the calculated locus of ^{56}Fe nuclei and solid lines span the 2σ range for scattered ^{238}U from a calibration experiment.

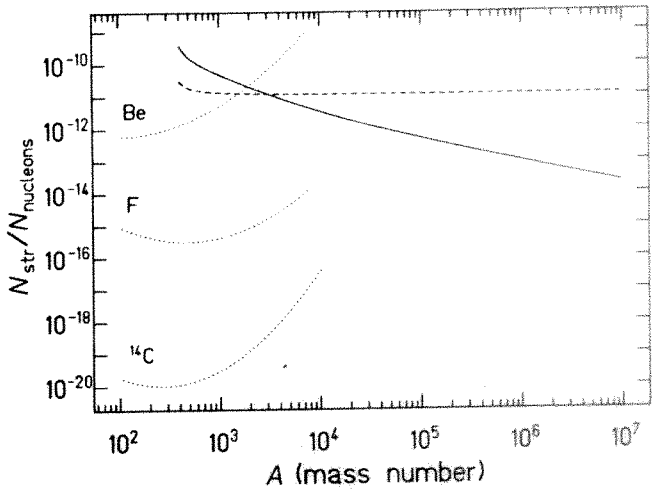

Fig. 3 Upper limits for the abundance of strange nuclei and supermassive relic particles (N_{str}) relative to the number of nucleons ($N_{nucleons}$) as a function of the respective mass A. The solid line represents the upper limit for the abundance of strange nuclei from Rutherford backscattering of ^{238}U in an iron meteorite, and the dashed line shows the upper limit for the abundance of supermassive relic particles from Rutherford backscattering of ^{238}U in a lanthanide sample. Dotted lines show upper limits for the abundance of supermassive relic particles from a search for heavy isotopes of light chemical elements[9].

the effective target thickness must be known. The latter depends on the scattering angle and the mass A. The charge Z, as a function of A, of the supermassive nucleus determining the Rutherford cross-section was taken from the calculation in ref. 2 (with parameter values $E/A = 899$ MeV and $\alpha_c = 0.6$). With other values of these parameters, the upper limits decrease by up to a factor of 20, so that our estimate is model dependent. The Rutherford cross-section was calculated assuming point-like colliding nuclei, which is a good approximation for masses of (strange) nuclei up to 10^4 because the minimal distance between the nuclei is several times their size. For larger masses the minimal distance from the surface of the strange nucleus to the projectile becomes comparable with the size of the strange nucleus, which could necessitate corrections to the Rutherford formula. At present, our knowledge of strange nuclei is insufficient to enable such corrections to be calculated. The upper limits are shown by the solid line in Fig. 3 as a function of the mass number A of the supermassive nucleus. There is increasing sensitivity with increasing mass because of the corresponding increase in the Rutherford cross-section.

The screening of the nuclear charge by electrons inside a large strange nugget could be important, making an estimate of the effective charge difficult. As Farhi and Jaffe explain[8], no appreciable screening occurs up to $A \approx 10^7$. We did not extend the estimated limits beyond $A \geq 10^7$ because above this, no reliable information on the screening was available. It is also important to note that the Coulomb barriers of strange nuggets are high enough[8] (except for nuggets of low atomic number) that elastic scattering is dominant at energies of 1.4 MeV per nucleon.

In addition to the iron meteorite, several terrestrial samples were studied using ^{238}U and ^{208}Pb beams: garnets, manganese nodules and the group of lanthanide elements extracted from the minerals apatite, monazite and bastnesite. The combined upper limits, not shown, are two times lower than those for the iron meteorite.

The dotted lines in Fig. 3 show results of a search for supermassive isotopes of light chemical elements, using an electrostatic spectrometer[9]. These isotopes were expected to be ordinary nuclei containing supermassive particles that are relics of the Big Bang[10–12]. The upper limits obtained for the abundance of supermassive isotopes with masses between 10^2 and 10^4 were rather low; we can consider these limits to be those for strange matter as well.

Our results, on the other hand, can be interpreted as giving upper limits for the abundance of supermassive relic particles that are bound to nuclei by hadronic interactions so that they cannot be detached in a collision process. Such limits are shown by the dashed line in Fig. 3 for relic particles attached to lanthanide elements. These limits can be considered as complementary to the previously published results (ref. 9 and references therein) because they cover a range of masses ($>10^4$ AMU) which was not investigated in ref. 9.

From our present knowledge of strange matter[2] we do not expect its properties and abundance to fluctuate from one atomic number to the next. Thus, a further improvement in sensitivity can be achieved with chemically enriched targets, particularly by using chemical separations[12] of elements which do not occur naturally, such as technetium[13], plutonium[14] or promethium. Strange matter with atomic numbers of these elements should be as stable and as abundant as that of neighbouring atomic numbers. Thus, by chemically separating these elements from bulk material it is possible to obtain targets enriched in strange matter by several orders of magnitude. A similar reasoning applies to supermassive relic particles[12].

Our limits for the abundance of strange matter are close to the instructive estimates of De Rújula and Glashow[3]. At present we do not consider it useful to put constraints on these theoretical considerations, because, for the samples investigated here, we cannot exclude the possibility of appreciable fluctuations in the concentration of supermassive nuclei caused by fractionations during chemical processes in the early Universe. Further studies of primitive meteorites, which have not been subjected to gravitational effects and whose composition reflects the primordial abundance of nuclei, may provide appropriate data from which to extract such constraints.

We thank E. Jäger, E. Schimpf, D. Gembalies-Datz, J. Asher, Y. Gil and M. Klin for their help in preparing the experiment. Advice and assistance from H. J. Beeskow, H. Daues and H. Stelzer is acknowledged. We are indebted to V. Dangendorf, D. Morrissey and Th. Wilpert for help and discussions. Financial support was provided by the Minerva Foundation (M.B., K.L., M.O.) and the Bundesministerium für Forschung und Technologie.

Growing drops of strange matter

Gordon L. Shaw*, Michael Shin*, Richard H. Dalitz† & Mukesh Desai*

* Department of Physics, University of California Irvine, California 92717, USA
† Department of Theoretical Physics, University of Oxford, Oxford OX1 3NP, UK

Strange matter comprises roughly equal numbers of up (u), down (d) and strange (s) quarks, in contrast to nuclear matter, for which s quarks are absent. The theoretical possibility[1–7] that S-drops (small 'bags' of strange matter) may not only be metastable, but might become absolutely stable if grown to sufficient size, would have consequences of the greatest importance. In particular, this form of matter could provide the basis for a compact energy source. Here we describe a hypothetical experiment to explore this possibility. The first step is the production and detection of S-drops in relativistic heavy-ion collisions. Previously, we have estimated[8] the efficiency of production of S-drops by the process of fragmentation of quarks into hadrons following formation of hot quark–gluon matter. The proposed experiment would initially produce and detect S-drops of charge $Z=-1$ in present CERN and BNL facilities. The next step would be to grow small, positively charged S-drops to large stable S-drops through neutron capture in a confining apparatus. These two steps could provide the scientific basis for subsequent engineering studies of S-drops as an energy source.

Considerable theoretical interest has centred on the intriguing possibility that not only may S-drops be very long-lived, but large extended such objects, comprising strange matter (S-matter), might be absolutely stable. A nucleus of baryon number A consists of neutrons and protons, each of which is made up of three (massless) non-strange quarks (udd and uud respectively) confined to a small 'bag'. Consider a single bag enclosing a total of $3A$ u and d quarks. This has a higher energy then the standard nucleus A. By replacing some u and d quarks by s quarks, however, the Fermi energies in the system can be lowered significantly. Neglecting the strange quark mass, m_s, the number of strange quarks n_s in this S-drop should be

$$n_s = n_u = n_d = A$$

Chin and Kerman[3] calculated that S-drops with $A > 10$ and $n_s/A > 0.8$ would be metastable with lifetimes $\tau > 10^{-4}$ s. More recently, Witten[5] made the startling suggestion that very large S-drops, indeed S-matter, with $n_s/A \approx 1$ might be absolutely stable, that is, the energy per baryon is <938 MeV. This has important implications for S-drops: neutron stars might actually consist of S-matter with essentially no crust, a possibility with interesting astrophysical consequences[5,9–13]. Of more general significance, however, is the possibility that a drop of stable S-matter could be used as an energy source, because, unlike nuclei, S-drops become more stable as they grow. It is this exciting idea that we wish to discuss here.

Using the Fermi-gas model with lowest-order quantum chromodynamics (QCD) corrections, Farhi and Jaffe[6] calculated that S-matter could be stable for an appreciable range of values of the QCD coupling strength and of m_s. Bethe *et al.*[14] argued against S-matter having a lower energy than nuclear matter. However, those authors approximated S-matter as being equivalent to an interacting gas of Λ particles, which is not a convincing model. As it seems likely that QCD calculations will not be accurate enough in the foreseeable future to give a definitive prediction on the stability of S-matter, experimental

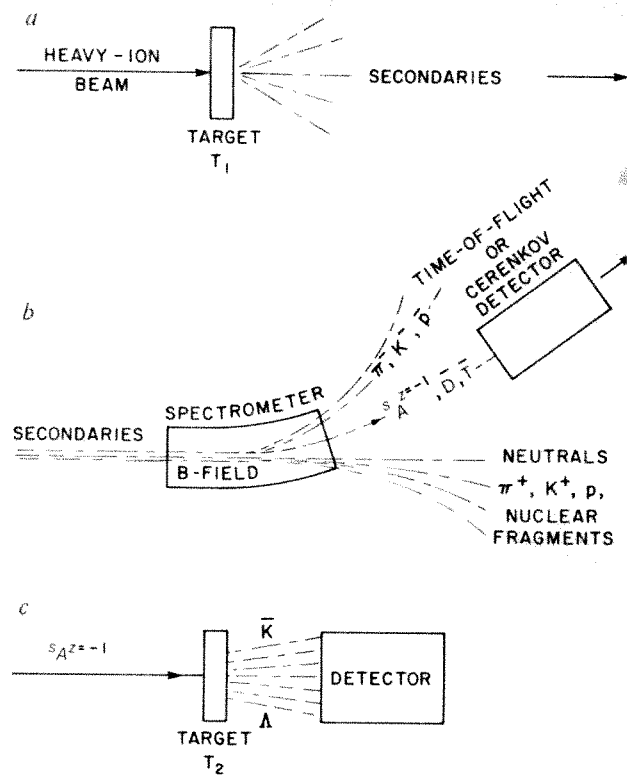

Fig. 1 A schematic diagram of the proposed high-sensitivity experiment to detect $Z=-1$ S-drops at CERN and BNL. *a*, Literally hundreds of secondaries will be produced in several types of processes on collision of the beam with target T_1. *b*, S-drops $^{S}A^{Z=-1}$ with momentum given by equation (1) are separated in the magnetic spectrometer. *c*, Positive identification of separated relativistic S-drops is made by secondary collisions in the downstream target T_2, producing a large number of $\bar{K}$ and Λ particles.

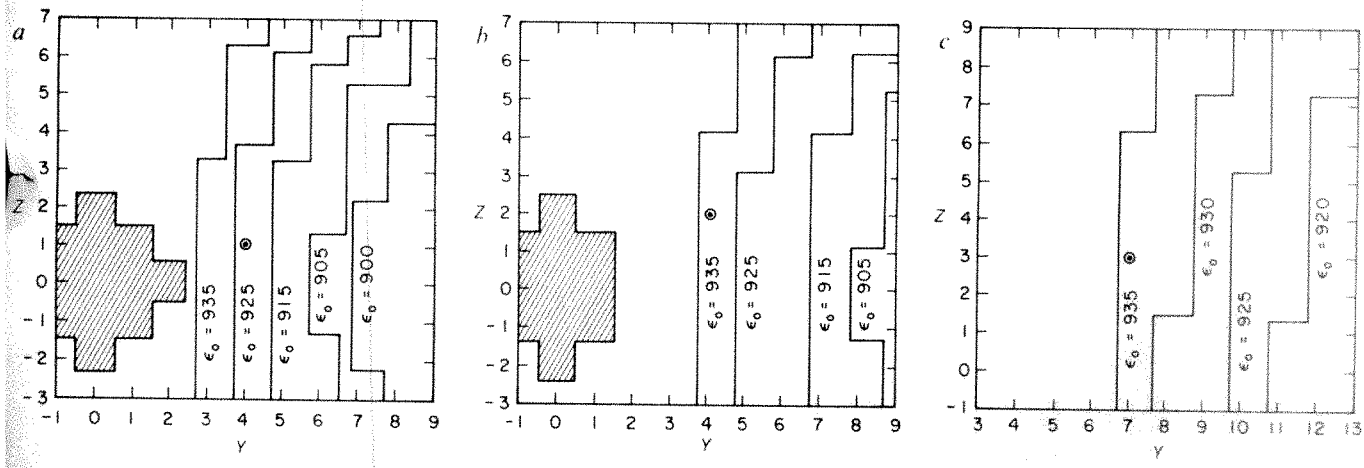

Fig. 2 Stability of S-drops against neutron emission by the strong and weak interactions for $m_s = 150\ \mathrm{MeV}/c^2$, calculated using the mass relations of Berger and Jaffe[7] for ${}^{S}A^{Z}$ as a function of ε_0, the energy per baryon for stable infinite S-matter. *a*, For $A = 15$, the S-drop is stable against neutron emission ($\Delta Y = -1$, $\Delta Z = 0$, $\Delta A = -1$) by the strong interaction if (Y, Z) is in the region to the left of the solid line for a given ε_0. Here, $Y = A + S$ is the hypercharge. For $\varepsilon_0 \leq 920$ MeV, the S-drop is also stable against neutron emission ($\Delta Y = 0$, $\Delta Z = 0$, $\Delta A = -1$) through the weak interaction for all (Y, Z). The unstable region against weak neutron emission, for $\varepsilon_0 = 925$ MeV, is shown by the shaded region. The solid circle at $(Y, Z) = (4, 1)$ is the location of the lowest-energy $A = 15$ S-drop. This is an S-drop ${}^{S}A^{Z} = {}^{-11}15^{1}$ with $n_d = 18$, $n_u = 16$ and $n_s = 11$. *b*, Same as *a*, but for $A = 20$. Again the shaded region corresponds to $\varepsilon_0 = 925$ MeV, and is a smaller domain than that in *a*. $(Y, Z) = (4, 2)$ is the energy minimum. *c*, Same as *a*, but for $A = 40$. For $\varepsilon_0 = 925$ MeV, there is no region unstable against weak neutron emission.

tests are necessary and warrant prompt attention in view of the significance of a positive outcome.

Consider step 1 of our proposed scenario, the production and detection of S-drops in the present relativistic heavy-ion-beam (fixed-target) facilities at CERN (200 GeV per baryon) and BNL (14.5 GeV per baryon). We assume that, as in the 'standard' picture of such collisions, a high-density, hot quark–gluon (QG) drop is formed[15]. We stress that the probability for forming such a QG drop need not be large and that a phase transition to a QG plasma need not occur for our proposal to be viable. (No real evidence for the formation of QG plasma has been found in the recent experiments[16] at BNL and CERN.) Liu and Shaw[8] calculated the emission of mesons and baryons in several (strong) interaction processes from a QG-drop precursor of an S-drop. The dominant process was the emission of high-momentum u and d quarks which 'fragment' and pick up an $\bar{s}$ quark from an $s\bar{s}$ pair to form a meson, leaving behind an s quark. (See also the mechanism for S-drop production of Greiner *et al.*[17].) The formation of many strange particles is typical of the observed events at CERN. Although model-dependent, the possibility of producing an S-drop with $n_s/A > 0.8$ from the QG drop was much greater for small-A ($\lesssim 30$) drops, this probability being quite appreciable. We imagine that an S-drop cools to a metastable state ${}^{S}A^{Z}$ (each s quark contributing a strangeness $S = -1$) mainly by the emission of mesons and photons. A range of states ${}^{S}A^{Z}$ will be produced. Although the detection of these S-drops is conceptually simple (because of the low Z/A ratio), it is technically very difficult because of the huge multiplicity of particles produced in a head-on collision.

We propose that a search be made for $Z = -1$ S-drops at CERN and BNL. Consider an S-drop ${}^{S}A^{Z=-1}$ produced in the QG matter formed from the relativistic collision between a beam heavy-ion with energy γ GeV per baryon ($\gamma \gg 1$) and a fixed-target heavy nucleis (Fig. 1*a*). We assume that on average each nucleon in a beam-ion interacts with one nucleon in the target nucleus; this defines a rest frame for S-drop production. The laboratory momentum of the S-drop then is

$$P_S \approx c(\gamma/2)^{1/2}({}^{S}A^{Z=-1})\ \mathrm{GeV}/c \qquad (1)$$

in a nearly forward direction. The key to the separation of these S-drops from other products in the magnetic spectrometer in Fig. 1*b* is that if A is greater than some reasonable minimum (~ 15) the S-drops will have a larger momentum than all the relevant background secondaries, specifically negatively charged π^-, K^- and $\bar{p}$. These latter particles, with mass m, would have momentum $P \lesssim c\gamma m$. In a field B, the spectrometer will bend particles in an arc of radius R according to $(P/Z)\ (\mathrm{GeV}/c) = 0.3\,BR$ (with B in tesla and R in metres), so that, taking $m = 1\ \mathrm{GeV}/c^2$, for ${}^{S}A^{Z=-1}_{\min} > \sqrt{2\gamma}$, all negatively charged π^-, K^- and $\bar{p}$ will be bent more than the S-drops, which may thus be separated from these negatively charged particles (as well as from the neutral and positively charged secondaries). At CERN, heavy-ion beams[16] having $\gamma = 60$ and 200 have been used, so that ${}^{S}A^{Z=-1}_{\min}$ will be 11 and 20 respectively. The only 'standard' background would come from $Z = -1$ antideuterons ($\bar{D}$) and antitritons ($\bar{T}$) which are produced in proton-nucleus collisions with rates[18] $\bar{D}/\pi^- \lesssim 10^{-5}$ and $\bar{T}/\pi^- \lesssim 10^{-9}$. The BNL heavy-ion beam[16] has $\gamma = 14.5$, and thus will not produce a $\bar{D}$ or $\bar{T}$ background. Central collisions might also produce negative, fractionally charged free quarks as a background; limits of $< 1.0 \times 10^{-9}$ quarks per incident oxygen ion have been set at BNL[19]. Following magnetic separation, Čerenkov detectors or time-of-flight detectors can then be used to distinguish between the ${}^{S}A^{Z=-1}$ drops and the low background of $\bar{D}$ or $\bar{T}$ at CERN. Finally, positive identification of these separated relativistic S-drops could be made in secondary collisions in the downstream target (Fig. 1*c*). The centre-of-mass energies will produce excitations much greater than the total binding energy of the S-drop, which will then disintegrate into a large number of $\bar{K}$ and Λ particles, giving a readily detectable and distinctive signature.

For an S-drop of given A, it is expected that the minimum-energy state will have positive Z. As can be seen from the mass relations of Berger and Jaffe[7], S-drops with negative Z will not be stable. (Perhaps this is fortunate, as stable negatively charged S-drops might interact with normal matter to grow without bounds.) However, we see that, for a considerable range in parameters, the $Z = -1$ S-drops will live sufficiently long (Figs 2 and 3) to perform the high-sensitivity experiment depicted in Fig. 1. More quantitative details will be published elsewhere.

Assuming that the production of these small $Z = -1$ S-drops is indeed detected as outlined above, let us turn to step 2, the growing of S-drops for their use as an energy source. It is clear that an intermediate step would be to optimize the production

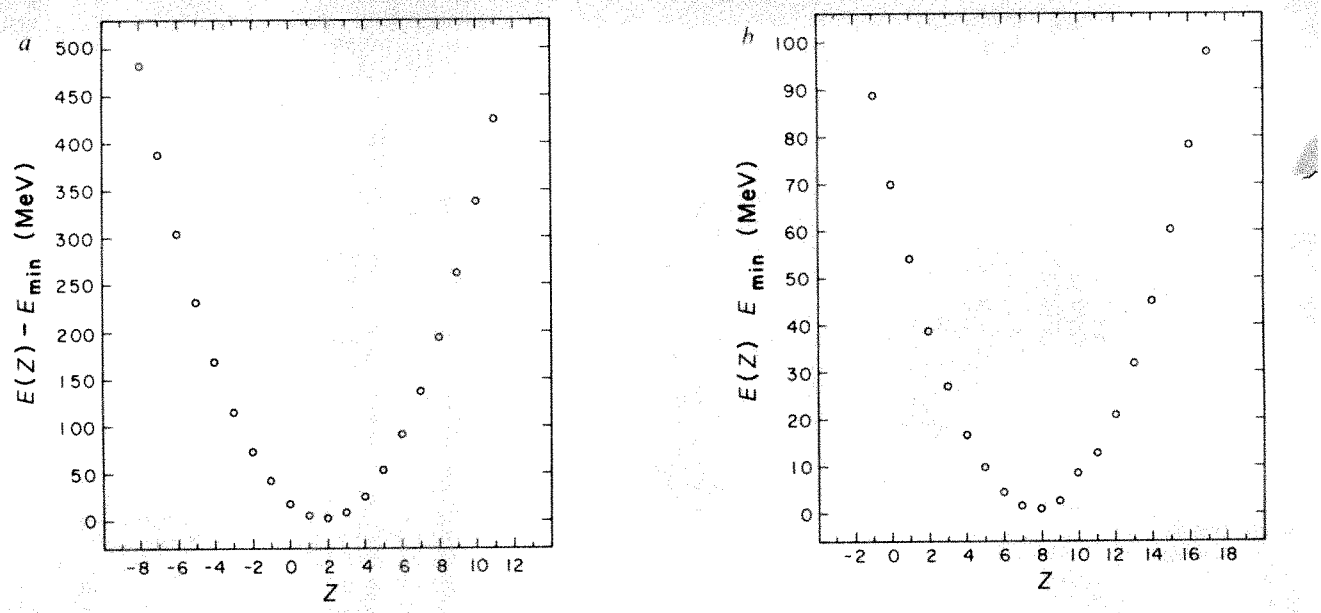

Fig. 3 *a*, Energy of the S-drop $E(Z)$, calculated using the mass relation of ref. 7, as a function of Z relative to its minimum value E_{min} ($\equiv E(Y = Y_{min} = 4, Z = Z_{min} = 2)$), for $A = 20$, $Y = Y_{min}$, $\varepsilon_0 = 920$ Mev and $m_s = 150$ MeV/c^2. This relative energy is rather insensitive to the choice of ε_0 (in the range 900–935 MeV). We note that an S-drop ${}^{S}A^{Z} = {}^{-16}20^{-1}$ would have an energy $\Delta E \approx 40$ MeV above the ground state ${}^{-16}20^{2}$, and $\Delta E \approx 20$ MeV above the ${}^{-16}20^{0}$ state to which it will decay by β-emission ${}^{-16}20^{0} + e^{-} - \bar{\nu}_e$. By scaling tabulated β-decay rates, we obtain the lifetime $\Gamma_{\Delta Z=1,\Delta S=0} \approx 10^{3}\,(\Delta E\ (\mathrm{MeV})/20)^{5}\ \mathrm{s}^{-1}$. Thus, this $Z = -1$ S-drop would live much longer than is necessary to perform the experiment proposed in Fig. 1. *b*, Same as *a*, but for $A = 100$ (for which $Y_{min} = 19$ and $Z_{min} = 8$).

and separation of the metastable (positive-Z) S-drops. We note that experimental and theoretical examination of the S-drops so produced, and their decays, will provide important information concerning the nature of the mass formula. The energy per baryon of stable infinite S-matter, ε_0, will thus be determined, as well as the quantitative details of the shell effects considered by Takahashi and Boyd[20].

The S drops produced and separated in the heavy-ion collisions should be grown as quickly as possible for at least the following reasons: (1) although stable against neutron emission for certain values of ε_0 (see Fig. 2), these S-drops might be unstable against α-decay, with lifetimes which, because of the Coulomb barrier, are long on experimental timescales (seconds) but not in relation to the needs for storage; (2) their binding energy per baryon grows with A; (3) their neutron-absorption cross-section increases as $A^{2/3}$; (4) their 'sticking' probability to a surface increases with A (that is, their thermal velocity decreases). Thus we propose a technique for rapid growth of relatively small (perhaps $A \geq 30$) S-drops to considerably larger (perhaps $A > 10^4$) ones, by passing through liquid deuterium in a confining apparatus as shown in Fig. 4. The small relativistic metastable ${}^{S}A^{Z=-1}$ drops are slowed down in a linear electrostatic decelerator to non-relativistic velocities. Near the end of this decelerator would be a tank of liquid hydrogen of length such that an S-drop passing through it would pick up two protons and emerge with a charge $Z = 1$. (Once $Z = -1$ S-drops are detected, one could infer that $Z > 0$ S-drops are also being produced at still higher rates. A major effort should then be made to optimize the production and the separation of these $Z > 0$ S-drops. This in turn would enable $Z > 0$ S-drops to be injected directly into the decelerator, obviating the need for a liquid-hydrogen tank.) An emerging ${}^{S}A^{Z=1}$ drop is then circulated through the liquid-deuterium tanks, where it picks up neutrons with a cross-section that we estimate (from nuclear (D, p) reactions) to be $\sim(A/30)^{2/3}\ 10^{-25}\ \mathrm{cm}^2$. An absorbed neutron in the S-drop would project onto its quark degrees of freedom and decay very rapidly by γ-transitions to the lowest allowed u and d levels. As neutrons are absorbed, the Fermi level of the d quarks increases relative to that of the s quarks, until a d → s transition takes place with subsequent γ-emission: following neutron capture, an S-drop ${}^{S}A^{Z}$ will relax towards it energy minimum by strangeness-changing weak decay ${}^{S}A^{Z} \rightarrow ({}^{S-1}A^{Z})^{*}$, which essentially changes a d quark to an s quark (u + d → s + u) in a charged weak-current interaction. The asterisk indicates an excited state, which decays rapidly by γ-emission. Scaling the similar decay ($K^{+} \rightarrow \pi^{+}\pi^{0}$), we obtain a decay rate

$$\Gamma_{\Delta S=-1,\Delta Z=0} \approx 10^{5}\left(\frac{\Delta E(\mathrm{MeV})}{20}\right)^{2}\ \mathrm{s}^{-1} \qquad (2$$

The $E(Y)$ curves required to evaluate (2) (where Y is the hyperchange $A + S$) are numerically very similar to the $E(Z)$ curves in Fig. 3.

Thus the S-drop grows and becomes more stable; we envisage small initial S-drops ($A \approx 30$–50, for which $Z_{min} \approx 3$) growing to a size $A \geq 10^4$. Our rough calculations of absorption length, Coulomb barrier, time constants and so on seem reasonable for

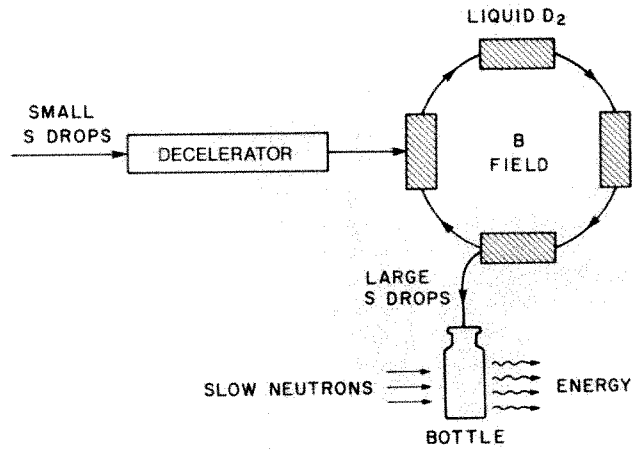

Fig. 4 Schematic diagram of proposed apparatus for the rapid growing of small S-drops into large S-drops. These can be stored and used as a compact energy source, by feeding in slow neutrons. For each neutron absorbed by an S-drop, $\sim(938 - \varepsilon_0)$ MeV of energy is released (mostly in γ-rays).

ne values $B \approx 1$ tesla, S-drop velocity $v/c \approx 0.1$ and a radius or the ring of tanks of ~5 m. Some acceleration of the S-drop etween liquid-deuterium tanks would be necessary to maintain $/c \approx 0.1$. The large-A S-drop may then be put into a 'conven-ional' storage bottle, where it decays to its stable Z_{min} and Y_{min} or that A. (Note that if we start from small Z values, and keep lways below Z_{min}, the Coulomb barrier for the S-drop will nhibit the possibility of α-decay until it has grown sufficiently arge to be stable against such decay.) These large stable S-drops ould then be used as a compact energy source.

Because stable S-matter may exist for a range of QCD par-meters, one might hope to be able to investigate its formation xperimentally. Our proposal, outlined schematically in Fig. 1, or producing and detecting small ${}^{S}A^{Z=-1}$ drops could be carried ut readily in present CERN and BNL relativistic heavy-ion ixed-target facilities. Our next proposal, outlined in Fig. 4, for apid growth of these small S-drops into larger ones, to be stored nd used subsequently as an energy source, seems plausible. We emphasize that our calculations of energies and lifetimes, given in Figs 2 and 3 and based on mass relations[7] for ${}^{S}A^{Z}$, hould be considered as only illustrative. No fine tuning of arameters is necessary for our general scheme to be viable. The use of the stable S-drops stored in the bottle (Fig. 4) as an nergy source appears conceptually simple. Slow neutrons are fed into the bottle; for each neutron absorbed by a large S-drop, an energy of $\sim(938 - \varepsilon_0)$ MeV is released, almost entirely in the form of γ-rays, and the S-drop becomes larger and more stable. In conclusion, therefore, we suggest that if S-matter is stable the production and growth of stable S-drops should be feasible and of considerable theoretical and pragmatic interest.

We thank B. French, M. Jacob, S. Moszkowski, H. Pugh, D. Silverman and G. Yodh for discussions.

Late-time optical spectra of SN1987A

Douglas A. Swartz*, Robert P. Harkness† & J. Craig Wheeler†

* Department of Physics, and † Department of Astronomy, University of Texas at Austin, Austin, Texas 78712, USA

Optical study of late-time nebular emission provided the first direct evidence for the presence of radioactive ^{56}Co in the ejecta of Type Ia supernovae[1] and yielded conclusive evidence that Type Ib events constitute a physically distinct class of supernovae[2]. Hydrogen-rich Type II supernovae have not been studied in detail in the nebular phase, but SN1987A provides an unprecedented opportunity to probe the structure and composition of the ejecta by modelling the nebular spectrum. Here we investigate the late-time nebular spectra of SN1987A by computing the emergent spectra from model atmospheres. The new features of this calculation are the inclusion of a complex model hydrogen atom and the self-consistent treatment of an opaque lower boundary which approximates the observed continuum. We adopt hydrodynamic models reported in the literature, which are known to reproduce the observed light curve and γ-ray and X-ray spectra, and we obtain qualitative agreement with observed optical spectra. By examining the effect of mixing core material into the envelope, we conclude that the metals in the hydrogen-rich envelope make a substantial contribution to the optical nebular lines even for models with no outward mixing of the core material; however, a significant fraction of the energy emitted in ^{56}Co decay must be deposited in the envelope to produce the observed linewidths and hydrogen line strengths.

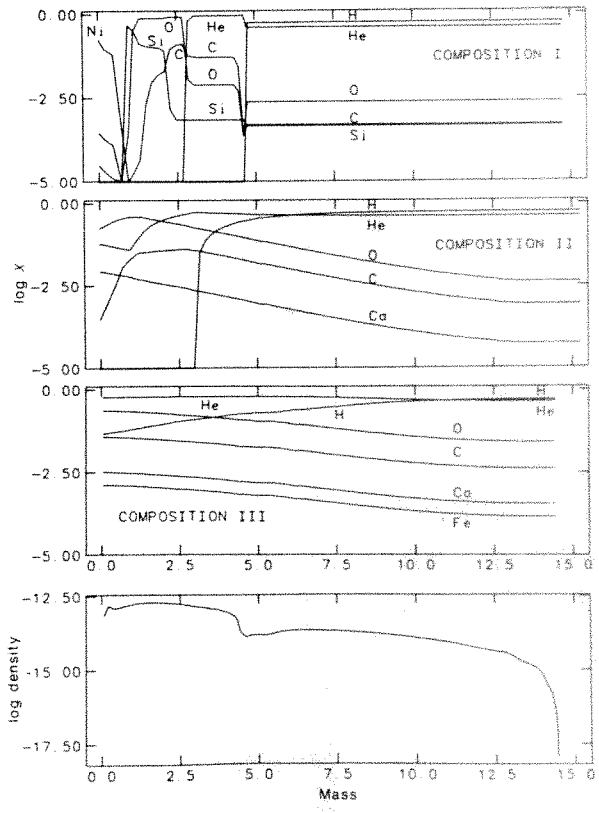

Fig. 1 Mass fraction X for several representative elements plotted logarithmically against mass for three mixed-composition models. Composition I (top) results from a standard one-dimensional hydrodynamic calculation. Compositions II (upper middle) and III (lower middle) are *ad hoc* mixed versions of composition I. The models correspond to models 10H (ref. 5), 10HM (ref. 9) and 10HMM (ref. 11), provided by S. Woosley (private communication). In the bottom panel is plotted the logarithm of the mass density against mass. Note the steep gradient near 5 $M_\odot$, corresponding to the helium/hydrogen interface of the initial model, which indicates a natural delineation between 'core' and 'envelope'. The neutron-star contribution has been removed from these plots and the mass coordinate rescaled appropriately.

Synthetic spectral diagnostics have been applied to the late-time conditions in supernova 1987A by Fransson and Chevalier[3]. They assumed a stratified core composition, with the radioactive heating source confined to the central regions, and neglected the hydrogen envelope. Their calculations did not incorporate the possibility of mixing of the composition. Recent theoretical investigations conclude that a large amount of mixing of the composition, and particularly of the radioactive ^{56}Co heating source, is required to accurately reproduce the light curve[4-10] and the γ-ray and X-ray spectral development[11-16].

Here we analyse the mixing scenario by presenting optical spectra from models with different degrees of mixing. We distinguish between 'composition mixing', which implies a smoothing of some part of the stratification that arises naturally in one-

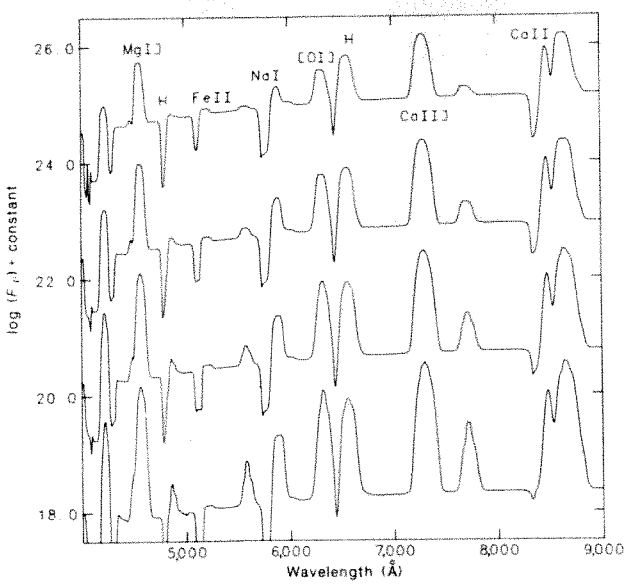

Fig. 2 Spectra for composition III at 200 days for various photospheric radii. From bottom to top, the radii are $R_{ph} = 1.5$, 2.0, 3.0 and 4.5×10^{15} cm, corresponding to mass points 1.1, 3.0, 4.6 and 7.5 $M_\odot$. For clarity the spectra have been shifted relative to each other by two logarithmic units on the vertical axis. Note the contribution to the lines from the 'envelope' mass (upper spectrum). In the lower two spectra, spikes are evident at the centre of the line profiles, arising from contributions from the exposed, slow-moving core material.

dimensional hydrodynamic models, and '^{56}Co mixing', which can be imposed on the model while maintaining stratification of the remaining elements. The distinction between composition mixing and ^{56}Co mixing is necessary to clarify our conclusions. One might imagine that the mixing of ^{56}Co, without mixing of the other elements, appears contrived. The possibility exists, however, that freshly synthesized material created in the deepest layers could penetrate into the envelope in the form of small, energetic 'clumps', which could provide extensive ^{56}Co mixing while preserving the original stratification of the remaining composition.

The techniques used here for computing the late-time spectra are similar to those employed previously for supernovae[1,17,18] and for SN1987A in particular[3]. The equilibrium structures of temperature and of ionization are found by imposing radiative and thermal equilibrium. Radiative equilibrium requires that heating of the gas must be balanced by radiation escaping the gas. It follows immediately that any given model will underestimate the total number of emission lines present in the real atmosphere and thus that the model can provide only an upper limit to the emissivity of the lines that are included.

We solve the radiative-transfer equations for the lines using the Sobolev approximation[19,20] with modifications[21,22] applicable to many-level and many-ion conditions. Special modifications necessary for solving the combined line-transfer and statistical-equilibrium equations for hydrogen will be discussed elsewhere (D.A.S., manuscript in preparation). We ignore continuum transfer. We do, however, mimic the effect of an optically thick inner region by imposing a lower boundary condition with a prescribed intensity I_ν^{inc} incident from below. The radius, R_{ph}, of this 'photosphere' and the frequency variation of the continuum are free parameters in the models. We require that the total luminosity L from the opaque region equals the true luminosity of the material that is heated radioactively below R_{ph}. We choose the continuum shape to be represented by a diluted black body at temperature T_{BB}, and define $L_{BB} = 4\pi R_{ph}^2 \sigma T_{BB}^4$. The dilution factor $\delta \equiv L/L_{BB}$ is fixed by energy conservation. The incident intensity is thus $I_\nu^{inc} = \delta B_\nu(T_{BB})$. For all models reported here a rough fit to the observed continuum shape is achieved with $T_{BB} = 5{,}000$ K. The dilution factor depends both on the selection of R_{ph} and on the extent of ^{56}Co mixing. The latter determines the actual luminosity at the photosphere. Many weak lines combine to form a quasi-continuum in the observer's frame which is smoothed further by electron scattering. Electron scattering will both broaden the observed line profile and decrease the luminosity at the line centre, because of the differential expansion of the atmosphere[18]. Our photosphere effectively smooths the detailed line spectrum that would be emitted from the material below R_{ph}, replacing it with a continuous spectrum. The core material of the atmosphere has a higher density and metal content (metallicity) relative to the envelope (see below); therefore, the electron density is relatively large and many weak metal lines are formed in the core. Our lower boundary condition most reasonably represents the natural conditions when it is placed within or immediately above the core.

This study is confined to hydrodynamic models and composition-mixing schemes for supernova 1987A that have been presented already in the literature. The canonical model comprises a 6-$M_\odot$ core, composed chiefly of helium and oxygen, and a 10-$M_\odot$ hydrogen-rich envelope. The inner 1.4 $M_\odot$ forms a neutron star. Three composition-mixing variations for this model are shown in Fig. 1. The variations correspond to models 10H (ref. 5) (composition I), 10HM (ref. 9) (composition II) and 10HMM (ref. 11) (composition III), which were provided by S. Woosley (private communication). The increased composition mixing represents successive improvements to the theoretical light curves and γ- and X-ray spectra reported in refs 5, 9 and 11.

We present results that are valid at 200 days after the supernova event, when the deeper layers may be observable. The placement of the lower boundary, R_{ph}, and the distribution of ^{56}Co are the only free parameters of the models. The total mass of radioactive ^{56}Co in all models is 0.075 $M_\odot$. Theoretical spectra for the 'standard' Type II-supernova model, consisting of a stratified core composition and with the ^{56}Co confined to the central region, are not consistent with the observed spectra of SN1987A. We therefore concentrate on models that incorporate various degrees of mixing.

Spectra of several models computed using composition III with different photospheric positions are shown in Fig. 2. For these calculations, the radioactive cobalt is distributed with constant mass fraction out to a mass cut of 14 $M_\odot$. The best fit to the spectral line strengths and shapes corresponds to $R_{ph} = 3.0 \times 10^{15}$ cm, a radius just outside the 'core'. The best fit to the continuum flux also occurs for this value of R_{ph}, although this result depends to some extent on the ^{56}Co distribution as well (see below). This same value of R_{ph} also produces the best results for models using compositions I and II. The spikes seen in the lower two spectra of Fig. 2 are accentuated in those models that feature increased stratification. These spectral features arise from the increased density in the low-velocity core region and are stronger for higher metallicity. Most of the metal lines for models using compositions I and II are too strong if the core regions are left exposed. We conclude that broad-band opacity effects become important below the core/envelope boundary.

For each of the three compositions we have calculated spectra assuming that the cobalt is distributed below a mass cut M_c of 5, 10 and 14 $M_\odot$ and assuming that there is a constant mass fraction of ^{56}Co below the cut. These mass cuts correspond to maximum ^{56}Co velocities of 1.3, 2.5 and 3.8×10^3 km s^{-1} respectively. The resulting spectra for these ^{56}Co mixing variations, using composition III, are shown in Fig. 3, for which the value $R_{ph} = 3.0 \times 10^{15}$ cm is adopted. For $M_c < 10\ M_\odot$ the hydrogen lines are too weak and all the spectral lines appear too narrow, as can be seen dramatically in the Ca II infrared triplet. The

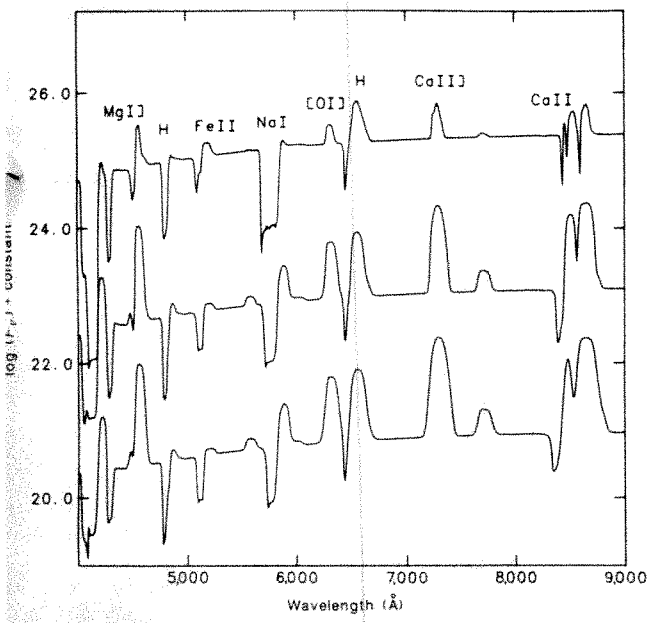

Fig. 3 Spectra for composition III at 200 days for different ^{56}Co mass distributions. The total ^{56}Co mass in all cases is 0.075 $M_\odot$. In all cases, the photosphere is located at radius $R_{ph} = 3.0 \times 10^{15}$ cm and the assumed temperature $T_{BB} = 5{,}000$ K. From bottom to top the ^{56}Co is distributed out to a mass point M_c of 14, 10 and 5 $M_\odot$. For clarity the spectra have been shifted relative to each other by two logarithmic units on the vertical axis. Note the increased continuum flux (most visible at the red edge of the spectra) for smaller M_c, which is due to the increased total luminosity from the opaque region. From bottom to top the luminosity at the photosphere is 5.7, 7.9 and 15.6×10^{40} erg s^{-1}.

same results occur for the other composition-mixing models with this value of M_c. The strength of the metal lines is satisfactory for composition III with $M_c = 5\ M_\odot$, because of the large mass of heavy elements mixed into the envelope in this model. The metal lines are not strong enough for compositions I and II when such a low value of M_c is used. We conclude that the best fit to the observed spectra occurs for $M_c \geq 10\ M_\odot$. Several studies[9-11] impose an outwardly decreasing mass fraction for the ^{56}Co distribution. We find that the optical spectrum is not sensitive enough to the details of the ^{56}Co distribution to differentiate between models with a gradient in ^{56}Co mass fraction and models with a constant mass fraction, provided that the decay energy is deposited throughout a major fraction of the ejecta. Our models require that the radioactive energy be deposited throughout a substantial fraction of the envelope; however, the cobalt could remain confined to the core if some mechanism exists for transporting the energy outward.

A comparison between the observed spectrum (M. Dopita, private communication) and the best results from the three mixing scenarios is presented in Fig. 4. The photospheric radius R_{ph} is 3.0×10^{15} cm (mass point 4.6 $M_\odot$) for all models, so that only envelope material contributes to the lines, and $M_c = 14\ M_\odot$. The lower metallicity of the unmixed model (composition I) provides the best overall fit, particularly at the red wavelengths, but all three models provide qualitative agreement with the observed spectrum. We cannot rule out any of these three models on the basis of these spectra, but composition I is preferred. The Ca II infrared triplet is too strong in all models by a factor of two or three. The Ca II] line strengthens as the metallicity increases and becomes too wide for composition III. As electron scattering tends to broaden the lines, we conclude that the fit for this line is poor for composition III. The strength of Hα is best for composition II although the red wing is weak in all models. The [O I] 6,300-Å line is accurately represented by the composition I model, as is the [O I] 6,300/[O I] 5,577 ratio. The Na I D-emission wing is too strong for all models by a factor

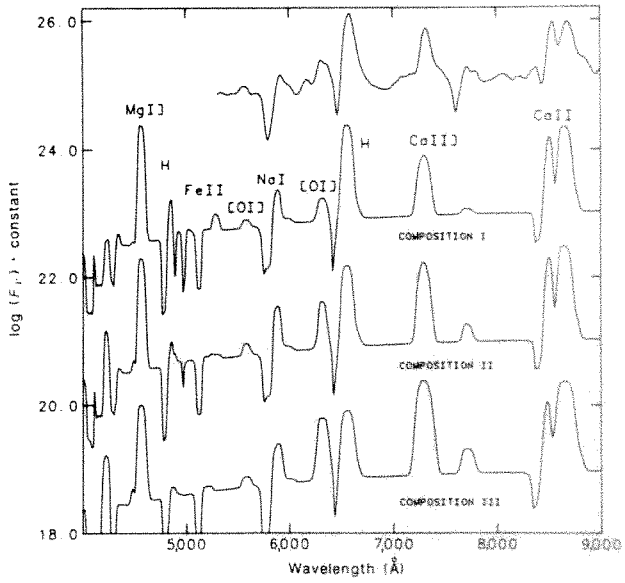

Fig. 4 Comparison of three mixed-composition models for observations at 200 days. From top to bottom the spectra are the observed spectrum (M. Dopita, personal communication) and models for compositions I, II and III. All models use $R_{ph} = 3.0 \times 10^{15}$ cm and $M_c = 14\ M_\odot$. For clarity the spectra are shifted vertically as before.

of two to three. At wavelengths shorter than those of the observed spectrum is the Mg I] 4,571-Å line. This line is very strong in all our models, including the many not discussed here. We note that this line is predicted to be strong by other models as well[3] but is not observed until much later times.

Based on these results, we conclude that (1) a good qualitative fit to the optical spectrum of SN1987A is obtained from the hydrodynamic models at 200 days if the lower boundary is placed just above the core; (2) the lack of observed narrow-line cores suggests that the dense slow-moving core region does not contribute substantially to the emission lines at 200 days; (3) a considerable contribution to the observed optical emission lines comes from the heavy elements in the envelope even if no composition mixing is invoked; (4) the radioactive decay energy must be distributed throughout a major fraction of the mass of the star ($M_c > 10\ M_\odot$) to be consistent with the observed spectrum; and (5) there is evidence for strong broad-band opacity at late times that is responsible for producing P-Cygni line profiles, as represented by our lower boundary.

Based on the limitations of computations used in this study, we further conclude that a large number of realistic model atoms, providing many spectral lines, is required to improve accuracy and that continuum-transfer effects should be included in future studies of this kind.

This research is supported in part by grants from the Robert A. Welch Foundation, the NSF and Cray Research, Inc. We are grateful to M. Dopita for providing the AAT data and to S. Woosley for providing the composition profiles studied here.

Rapid variability of extragalactic radio sources

A. Quirrenbach, A. Witzel, T. Krichbaum, C. A. Hummel, A. Alberdi & C. Schalinski

Max-Planck-Institut für Radioastronomie, Auf dem Hügel 69, D-5300 Bonn 1, FRG

Since its discovery more than 20 years ago[1,2], variability of extragalactic radio sources on timescales of weeks to years has been the subject of many investigations. Little is known, however, about radio variability of extragalactic sources on timescales of less than a few days. Variations on timescales of hours—mostly at millimetre wavelengths—have been reported for several sources[3–6]. Heeschen *et al.*[7] have found variability with amplitudes of up to 12% in less than 1 day at 11-cm wavelength in a sample of northern ($\delta \geq 60°$) compact sources. We have continued these observations at wavelengths of 6 and 11 cm using the 100-m telescope of the Max-Planck-Institut für Radioastronomie and report here the results for two sources. The quasar QSO0917+62 showed variations with amplitudes of up to 23% in ~24 hours, which were correlated at the two wavelengths; in the BL Lac object 0716+71 we found variations with amplitudes of 7–11%. We discuss intrinsic effects, gravitational lensing and scattering in the interstellar medium as possible explanations for rapid radio variability.

The observations were made in two sessions in 1988: 31 March to 5 April (112 hours, 6- and 11-cm observations made almost simultaneously) and 15–20 June (104 hours, 6 cm). For the 11-cm measurements we used a correlation receiver (cold-load reference) with a bandwidth of 80 MHz and a system temperature of 55 K; the 6-cm measurements were performed using a dual-beam correlation receiver with a bandwidth of 500 MHz and a system temperature of 65 K. Both receivers have circularly polarized feeds and are mounted in the secondary focus of the 100-m telescope. For each observing epoch, our sample included nine flat-spectrum compact sources (spectral index $\alpha_{11}^{6} \geq -0.5$; flux density $S \propto \nu^{\alpha}$) and seven or eight steep-spectrum reference sources of similar flux densities. The observations consisted of cross scans in azimuth and elevation through the source position, thus allowing for accurate correction of pointing errors (see Heeschen *et al.*[7] for details of the observations and data-reduction procedures, including corrections for gain and extinction). In addition, the influence of weak confusing sources was estimated from the difference of scans in azimuth and elevation as a function of parallactic angle; a corresponding correction was applied to the 11-cm data of six sources. The sum of all corrections applied to the raw data never exceeded 2%. For all sources we calculated a percentage fluctuation index $u = 100\ \sigma/\langle S \rangle$, where $\langle S \rangle$ is the mean flux density of the source in the observing session and σ is the standard deviation of single measurements. The errors are dominated by systematic errors (that is, proportional to S); their level is given by the mean fluctuation index for steep-spectrum sources, which is 0.27% at 11 cm and 0.35% at 6 cm wavelength. (The value at 11 cm wavelength reproduces exactly that of Heeschen *et al.*[7].) As none of the included steep-spectrum sources showed peak deviations of more than 1% from their mean flux densities (see for example 0951+69 in Fig. 1*a*), instrumental artefacts above this level can be excluded.

Of all observed sources, the quasar 0917+62 showed the largest variability during both sessions: 22% (peak-to-peak) at 11 cm and 14% at 6 cm in the March/April run, and 23% at 6 cm in June. In the figures, normalized variations $R = 100\ (S/\langle S \rangle - 1)$ are plotted against time. The fastest 'events' occurred at 6 cm wavelength in March/April; our ~75-min sampling after JD 2447255.4 reveals fine structure in the light curve on a scale of ~4 hours (Fig. 1*b*). The variations for the 11-cm data (Fig. 1*a*) are similar but much smoother; however, they show a remarkable discontinuity of the slope at JD 2447256.0, at about the same time as the secondary maximum at 6 cm. Two similar discontinuities are apparent in the 6-cm data for June (Fig. 1*c*), as well as a spike-like feature at JD 2447331.1, the amplitude of which is significantly above the uncertainty level. For the single observations of 0917+62 in March/April, the 6-cm variations are faster than the 11-cm variations by a factor of about three. We also note that, from visual inspection of the light curves, there is the suggestion of a time lag of ~1 hour near the minimum at JD 2447255.6, with the 11-cm data lagging behind the 6-cm data (Fig. 1*a* and *b*). A formal cross-correlation analysis of the full data set gives a time lag of 0.5 ± 1 hours. In 1985, 0917+62 was observed twice at 11 cm wavelength[7]; it was variable in both sessions, with amplitudes of 3.4% and 8% respectively.

In contrast to 0917+62, the BL Lac object 0716+71 showed quite different light curves at 6 cm and 11 cm in the March/April dual-frequency run; it is not obvious how these two curves are related to each other. This could imply a time lag longer than the length of our observing period, or it may be that the variations at 6 and 11 cm are indeed unrelated. The light curves of 0716+71 also show significant fine structure on timescales of a few hours, which were not adequately sampled (Fig. 1*d*). In each of the four sessions during which it was observed since 1985, 0716+71 showed a remarkable consistency of behaviour; its variability was always in the narrow range of 7–11%.

We note that rapid radio variability seems to be a quite common phenomenon. It was observed in 6 out of 15 sources by Heeschen *et al.*[7]; three of the sources are classified as quasars and three as BL Lac objects. These sources had been selected on the basis merely of their high declination, flat spectrum, and high flux density. Furthermore, the occurrence of a similar effect—a 7% decrease of the 6-cm flux density in slightly more than 1 hour—in OJ287 (ref. 6) indicates that it is not limited to the north-polar region. On the basis of up to five observing periods now available for several sources, it seems that rapid variability is not distributed randomly among compact sources, but rather that it appears quite regularly in the same sources each time they are observed. Thus this phenomenon is connected either to certain characteristics of the sources (besides compactness, which seems to be a necessary but not sufficient condition) or to their positions in the sky. As is already apparent from the two cases of 0716+71 and 0917+62, the detailed wavelength dependence of the variations—including cross-correlation and possible time lags—is different in the observed sources, but the amplitudes at 6 and 11 cm wavelength are similar.

At least three different mechanisms could explain the observed variability: intrinsic effects, gravitational (micro-) lensing and refraction in the interstellar medium (scintillation).

Although the variability on somewhat longer timescales observed at high frequencies, in 3C279 and OJ287 for example, is connected to variations in the degree and angle of polarization and is therefore generally interpreted as being intrinsic[8,9], it is difficult to attribute variability as rapid as reported here to intrinsic effects. Standard light-travel-time arguments would lead to extremely small source diameters and therefore to brightness temperatures as high as 2×10^{17} to 7×10^{18} K (under the

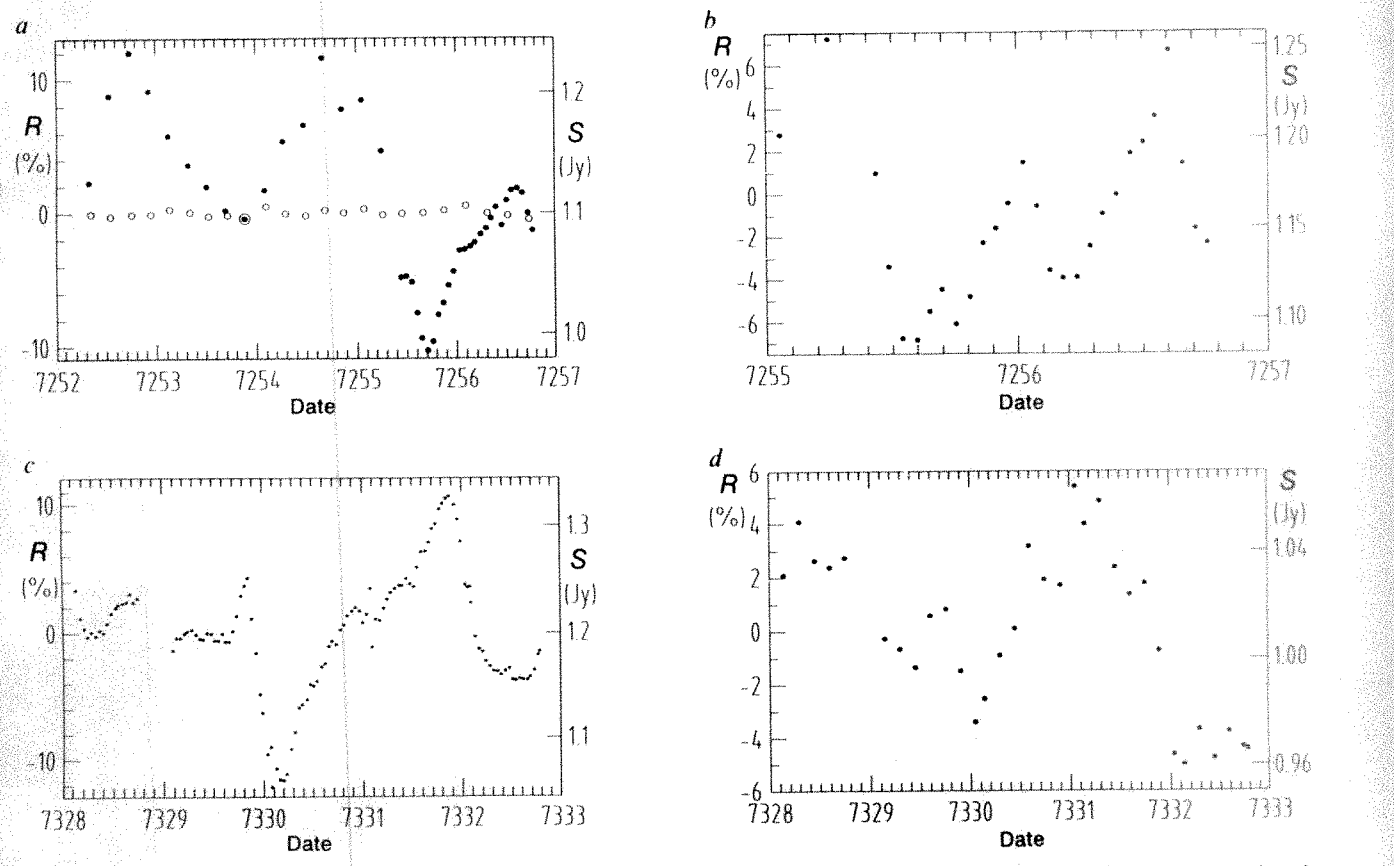

Fig. 1 *a*, Flux density (S) of 0917+62 (filled circles) and the steep spectrum reference source 0951+69 (open circles) at 11 cm wavelength in March/April 1988 against date (JD−2440000). Normalized variations R are defined as 100 ($S/\langle S\rangle-1$). The data for the steep spectrum source indicate the total measurement errors. The absolute scale applies to 0917+62. *b*, Flux density of 0917+62 at 6 cm wavelength, March/April 1988. *c*, Flux density of 0917+62 at 6 cm wavelength, June 1988. *d*, Flux density of 0716+71 at 6 cm wavelength, June 1988.

assumption that the unknown redshift of 0917+62 lies in the range 0.1–1), so that for incoherent synchrotron radiation, Doppler boosting factors of 50–200 would be needed to meet the Compton limit of about 10^{12} K (ref. 7). The same argument applies to scattering by material within the quasar or at cosmological distances: either the source of radiation must be very small, or the apparent relative transverse velocity must exceed ~100c. Coherent mechanisms could also produce fast intrinsic variability, but no convincing evidence for those processes has been found so far. Normally, intrinsic variability is larger at shorter wavelengths, in contrast to the variations observed here, but with the present limited understanding of the relevant physical processes we cannot rule out intrinsic effects as a possible explanation.

If the radiation from a distant quasar passes through an intervening galaxy, one must take into account the relativistic light deflection not only by the whole galaxy but also by individual stars[10]; the combined effects of many stars lead to a distribution of caustics in the source plane. Calculated model light curves look qualitatively very much like those shown here: they show similar discontinuities of the slope, which reflect the convolution of the moving source structure with the distribution of caustics[11,12]; the details depend on the models adopted for the lensing galaxy and the source structure. Gravitational lensing is sensitive to wavelength only through the wavelength dependence of source size and shape, so that it can explain the observed similar variations at 6 cm and 11 cm. Nevertheless, of the above mentioned explanations, gravitational micro-lensing seems the least probable, because we could not find, on the POSS plates, any obvious lens candidates in the fields of 0716+71 and 0917+62. Furthermore, to produce a noticeable effect, the source size cannot be much larger than the variability timescale multiplied by the velocity of light. This leads to about the same source size as required by intrinsic explanations and thus encounters the same difficulties.

Scattering by the interstellar medium is believed to cause low-frequency variability[13,14], as well as flickering at ~10 cm wavelength on timescales of several days to weeks[15,16]. Unusual features in the light curves of compact extragalactic sources sampled once per day[17] are also attributed to scattering by compact structures in the interstellar medium. In the single-scale model, the timescale is simply given by the spatial scale divided by the relative velocity. For galactic velocities of 200–300 km s^{-1} or less, the durations of about a day for single events then imply that the scattering density fluctuations cannot be much larger than ~0.1 AU. The electron density n_e of single scattering blobs can be estimated from $\theta \approx (2\pi)^{-1} r_e \lambda^2 n_e$, where θ is the refraction angle, r_e the classical electron radius and λ the wavelength of the observation. For $\theta \approx 1$ milliarcsec this yields $n_e \approx 10^3$ cm^{-3} and thus a mass of $\sim 2\times10^{16}$ g. At a distance of 1 kpc a scatterer of diameter 0.1 AU covers $\sim 10^{-18}$ sr, so a total mass of $\sim 2\times 10^{34}$ g, or 10 $M_\odot$, is needed to reproduce the observed scattering probability. Although very little is known about the structure of the interstellar medium on scales as small as those involved here, and although electron densities of 10^3 seem quite large, the extreme scattering events[17] give strong evidence for the presence of such clouds. Because of the small timescales present in our data, refractive interstellar scintillation in a medium with a power-law wavenumber spectrum and the standard parameters given by Rickett[18] gives no consistent results, unless the distance to the scattering screen is reduced to ~50 pc. Normally scattering by the interstellar medium is expected to have higher amplitude at lower frequencies, but again the dependence of source size on wavelength may lead to equal amplitudes at different frequencies[19,20], or even to higher amplitudes at higher frequencies, as observed in the extreme scattering events[17]. In this framework,

caustics may also be relevant[21], thus providing an explanation of the observed shapes of the light curves as mentioned above.

Because our sample sources were selected on the basis of their high declination, they all lie in the same region of the sky, which happens to be close to the galactic loop III. It seems possible that the observed variability is connected to this old supernova remnant[7] or to the high-velocity features present in the same area[22,23]. This interpretation is not completely satisfactory, however, because OJ287 shows a similar behaviour[6], but is not located near any known feature resembling the galactic loops.

It is obvious that, irrespective of its reason, variability with amplitudes of several per cent and timescales of hours causes severe problems to aperture-synthesis observations, whose dynamic range may be limited by fluctuations in the source brightness as small as 1% (refs 7, 19). Thus for observers who wish to map low-brightness features in strong sources, to look for weak images in gravitational-lens systems or to investigate clustering of radio sources, it is very important to know in detail the characteristics of rapid variability.

We thank Drs W. J. Altenhoff, D. Graham, R. Porcas and A. P. Rao for stimulating discussions.

Slowly moving thermal features on Jupiter

J. A. Magalhães*, A. L. Weir†, B. J. Conrath‡, P. J. Gierasch† & S. S. Leroy†

* NASA/Ames Research Center, Moffett Field, California 94035, USA

Obtaining measurements of winds on the jovian planets—Jupiter, Saturn and Uranus—at depths other than the level of the observed visible clouds has long been a problem preventing an understanding of the dynamics of these deep atmospheres[1,2]. Measurements of horizontal thermal structure on Jupiter suggest that the observed zonal (west–east) jet system decays slowly above the visible clouds, persisting over many pressure-scale heights[3]. The ubiquitous visible cloud cover, believed to be composed of ammonia ice crystals lying somewhere between the 700-mbar and 300-mbar pressure levels[4], prevents direct sensing below these levels, so the depth of the wind system remains unknown. Here we report that maps of upper troposphere temperatures derived from Voyager 1 and Voyager 2 infrared interferometer spectrometer (IRIS) spectra show large-scale features which move very slowly; the motion is very different from the inferred local fluid velocity. We suggest that these features may be indicative of a deeply-rooted fluid dynamical regime beneath the surface meteorology, although other explanations are possible.

The Voyager IRIS instruments obtained measurements of the thermal emission of Jupiter over the spectral range 4–55 μm (ref. 5). During the encounters with Jupiter, at a distance of about 3×10^6 km before and after closest approach, the instruments were used to map the planet globally by scanning from north to south along the sub-spacecraft meridian for one rotation of the planet, to produce north–south maps with a spatial resolution of about 10 degrees of longitude at the sub-spacecraft point. Between these sequences, higher-spatial-resolution observations of selected features were obtained. The spectra have previously been inverted to deduce the temperatures at the 270-mbar and 150-mbar pressure levels, the ammonia abundance, and cloud optical depths at 5 and 45 μm (refs 3, 6). Cylindrical projection maps, in the form of digital images, have been created for each of these quantities from the inbound and outbound north–south mapping sequences obtained by Voyager 1 and the inbound map from Voyager 2. Zonal-mean motions as a function of latitude have been evaluated from time-lapse map pairs by using a line-by-line correlation technique previously applied to Voyager imaging mosaics[7]. The velocity resolution for the time interval between the inbound and outbound maps from Voyager 1 is 30 m s^{-1} and for the time interval between Voyager 1 and Voyager 2 is 1 m s^{-1}, based on the IRIS instrument beam size.

Figure 1 displays the correlations between the Voyager 1 inbound and outbound north–south maps of temperature at a pressure of 270 mbar, and of cloud optical depth at 45 μm. The well defined and continuous line of maxima shows that meaningful correlations have been achieved, and this line defines a zonal displacement profile. The most striking difference between the images is the absence, in the temperature correlation image, of the broad region of positive displacement near the equator. Figure 2 shows the displacements corresponding to the maxima from Fig. 1, in units of zonal wind, and the linear-correlation coefficients. Based on a sampling of one observation point every ten degrees, the probability of achieving a correlation coefficient of 0.4 or better for one longitude strip from a random sample of uncorrelated observations is less than 2%. Plotted along with the IRIS results is a zonal-mean-wind profile derived from Voyager imaging-camera data that has been degraded to the same spatial resolution as the IRIS north–south maps. The wind profile from the infrared–optical-depth maps is in good agreement with the visible-imaging profile to within the spatial and velocity resolution limits. In the equatorial region a broad, strong prograde jet exists and is much wider than the spatial resolution of the IRIS beam. Jets observed at higher latitudes with the imaging camera are too narrow to be resolved by the IRIS instrument. Although wide enough, the strong jet at 24° N is not detected because of the lack of longitudinal structure. The results in Fig. 2 indicate that the infrared data is capable of recovering the low-latitude cloud motion field but that the dominant thermal structures do not participate in its motion.

Longitudinal scans from both the ingoing and the outgoing Voyager 1 maps of the 270-mbar temperature field and cloud optical depths at the equator are plotted in Fig. 3. The outgoing scans have been displaced in longitude by the correlation results to compensate for zonal drift and to facilitate comparison of structures. The largest-amplitude thermal structures at 270°, 210° and 60° longitude clearly show the features determining the correlation result. Some weak features do not coincide for the two scans and may drift at the higher rate of cloud features, but enough agreement exists such that identifications can be

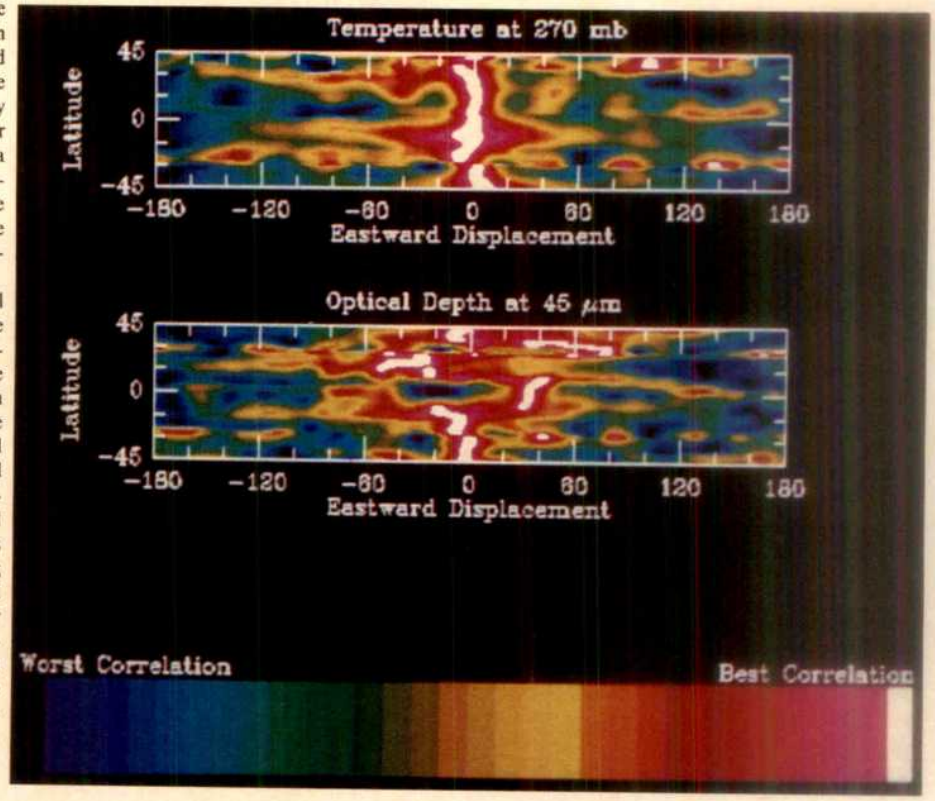

Fig. 1 Correlation images for temperature at 270 mbar (top) and aerosol optical depth at 45 μm (bottom) from Voyager 1 inbound and outbound north–south maps. The value of the correlation function is represented by variations in colour and is displayed for each line of planetographic latitude as a function of eastward longitudinal displacement (degrees) between the lines of the inbound and outbound maps. A positive shift of 30° corresponds to a prograde velocity of ~100 m s^{-1} at the equator.

Method. Cylindrical-projection digital images of the north–south maps used in the correlations were produced by first subtracting the zonal average of the quantity at the latitude of the observation from each measurement. Then the value of the image at each pixel was expressed as a sum of all observations within a given range weighted by a modified gaussian function of the distance between the pixel and the original observation point. This procedure is necessary because the IRIS is a non-imaging instrument. A correlation image is produced by evaluating the correlation function for corresponding lines of a map pair as a function of longitudinal displacement between the lines. For each line of latitude the maximum and minimum correlation-function values are assigned to the corresponding ends of the colour scale.

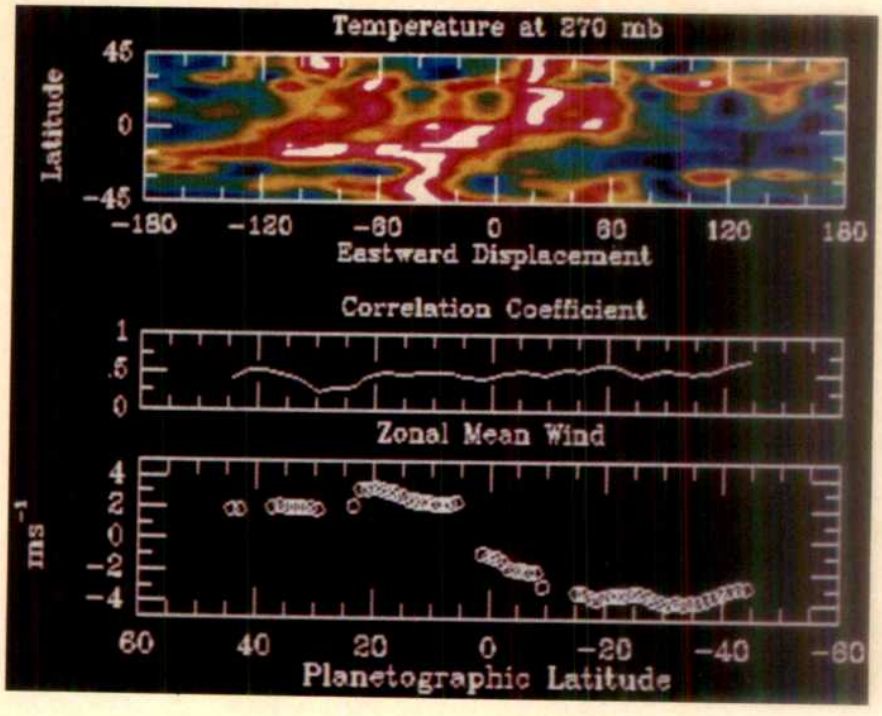

Fig. 4 Correlation results for temperature data (270-mbar level) from Voyager 1 and Voyager 2 inbound maps. Top, Correlation image. Bottom, Zonal velocity versus latitude from the line of maxima in the correlation image. Middle, Linear correlation coefficients from the maxima. See legends to Figs 1 and 2 for further explanation.

made. The small thermal contrasts of the dominant structures are well above the formal noise level of the IRIS. The cloud-optical-depth scans show some structural agreement, although significant changes have occurred; temporal variability in the atmosphere and zonal variation in the wind can lead to such changes. The linear-correlation-coefficient values provide a quantitative measure of the agreement between pairs of scans. The lower correlation coefficients of the optical depths as well as the longitudinal scans in Fig. 3 show that the horizontal cloud structure is more variable than the thermal structure. This result is consistent with Jupiter's pronounced visible variability, which exists in spite of the overall stability of the jet system[1,2].

Further evidence of slowly moving thermal features can be obtained in at least one latitude range. During the closest approach by Voyager 1, Jupiter was longitudinally well sampled between 5° and 15° N at high resolution (about 2 degrees of longitude at the sub-spacecraft point). Fitting a Fourier series to the thermal data retrieved from this sequence, as well as to the corresponding original values in the inbound and outbound north–south maps (that is, before they were made into images), shows a strong component at a wave mode of 9. A least-squares fit of the phase velocity of this wave between all three data sets

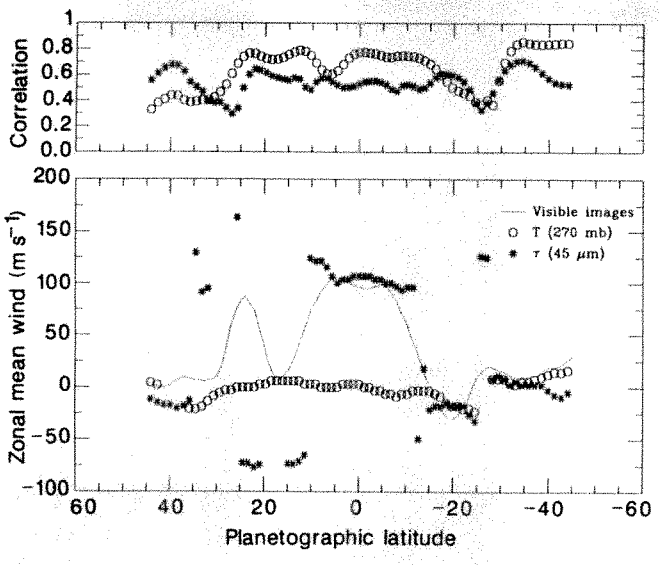

Fig. 2 Zonal velocity versus latitude from temperature (at 270-mbar level), optical depth (at 45 μm) and Voyager 2 violet-image correlations (bottom panel only) (dashed line). The velocities are derived from Fig. 1 by expressing, in units of zonal wind, the displacements associated with the correlation-function maxima. Some missing points are evident at selected latitudes, where spurious correlations occur. Linear-correlation coefficients of the maxima are displayed in the top panel for the infrared results. The visible image velocities are obtained from Voyager 2 violet-image mosaics and have been degraded to the spatial resolution of the IRIS.

yields a value of 10.5 ± 12.4 m s^{-1} (recall that the dynamically important quantity is the phase velocity relative to the mean flow, which, for this range of the total phase velocity, is large and negative).

The high correlation coefficients for the temperature data from Voyager 1 suggest that correlation with the Voyager 2 thermal map might be possible. Moreover, the upper bound on the drift of features provided by the Voyager 1 results indicates that the thermal structures would drift by significantly less than one planetary circumference during the time interval between the Voyager 1 and Voyager 2 encounters (~4 months). Thus, velocities could be obtained unambiguously from the correlations. Figure 4 displays the results of such a correlation. The line of maxima is remarkably continuous and well defined, and suggests that meaningful correlations have been achieved, although the maxima are broader, and the correlation coefficients somewhat lower, than the Voyager 1 results. The line of maxima shows a striking antisymmetry about the equator with an amplitude of ~2-4 m s^{-1}. The velocity corresponding to the maximum at 23° S latitude agrees with the velocity of the Great Red Spot inferred from imaging data[2] to within the formal velocity resolution based on the IRIS beam size (~1 m s^{-1}). A more conservative estimate of the velocity resolution is the width of the half-maximum point of the correlation, which yields a resolution of ±5 m s^{-1}; this resolution is still significantly better than that of the Voyager 1 map correlation. In Fig. 2 the longitudinal scans of the equator show structures at longitudes 270°, 200° and 70° which match the Voyager 1 features, although the matches are certainly not as clear as those in the comparison of Voyager 1 inbound and outbound maps.

The zonal winds in the upper troposphere of Jupiter are believed to be comparable to the winds seen in the clouds, because the vertical zonal-wind shear at these levels is quite small[3]. Although thermal perturbations that drift with the tropospheric currents undoubtedly exist, they are apparently of such small amplitude or horizontal scale that the IRIS beam does not resolve them. The thermal features described here drift slowly with respect to the bulk rotation of the planet as inferred from radio observations[1] and far more slowly than the local aerosol velocity (~100 m s^{-1}). If the thermal perturbations producing these structures are excited in a region where the fluid velocity is comparable to the observed equatorial jet, then the observed motion of the structures would represent a large negative phase velocity with respect to the fluid, and this phase drift would need to have a magnitude sufficient to nearly cancel the fluid motion. Because such nearly exact cancellation of the equatorial jet velocity by the phase velocity seems improbable we believe that the slowly moving thermal features must be excited in a region of slow or no motion. The excitation could result from the influence of dynamical structures in a slowly moving deep atmospheric circulation, from horizontal propagation from slowly moving features at higher latitudes (such as the Great Red Spot), or from upper-atmospheric or magnetospheric features moving with the planetary rotation. We consider the last possibility to be unlikely because of the relatively small energy content of the upper atmosphere. Horizontal propagation may be possible but would need to extend across large horizontal zonal-wind shears. We conclude that the thermal features described here probably represent the influence of slowly moving dynamical structures below the visible clouds on Jupiter.

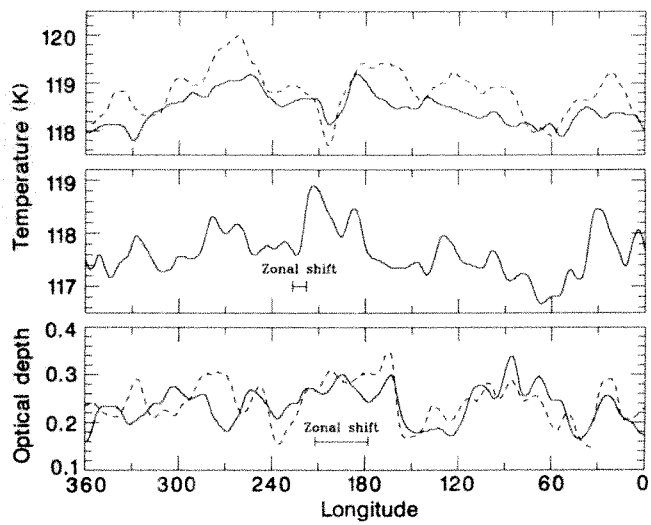

Fig. 3 Longitudinal scans of the equator from Voyager IRIS maps of temperature and optical depth. Top, Scans of temperature from Voyager 1 inbound (solid line) and outbound (dashed line) maps. Middle, Scan from Voyager 2 inbound map. To facilitate comparison of thermal structures, the Voyager 2 scan has been displaced to compensate for zonal drift using the correlation displacement; the size of the shift is displayed. Bottom, Scans of cloud optical depth from Voyager 1 inbound (solid line) and outbound (dashed line) maps. The outgoing map scan has been displaced to compensate for zonal drift using the displacement from the correlation-function maximum in Fig. 2; the size of the shift is displayed at the bottom of the panel.

Previous efforts at inferring the dynamics and structure below the clouds have used wave signatures or flow fields in the visible cloud layers combined with modelling to draw inferences about deep physical properties[9,10]. However, such inferences are somewhat ambiguous and limited to particular regions. These techniques are similar in spirit to seismic studies of the Earth's internal structure and to acoustic-gravity-wave sounding of the Sun[11]. The thermal anomalies reported here may provide a new means of probing Jupiter.

Direct ozone depletion in springtime Antarctic lower stratospheric clouds

D. J. Hofmann

Department of Physics and Astronomy, University of Wyoming, Laramie, Wyoming 82071, USA

It is now generally accepted that springtime Antarctic ozone depletion in the atmosphere between 17 and 22 km is related to the presence of ClO produced through heterogeneous chemistry on the surface of polar stratospheric cloud particles[1,2]. Below 17 km, however, where ozone depletion also occurs[3], a causal link with ClO has not been established because of apparently low ClO values. Vertical motions, associated with mountain lee waves and the formation of nacreous clouds, also seemingly cannot explain observed ozone depletion[4]. Here we present balloon measurements of ozone and cloud particles in the lower stratosphere (10–17 km) at McMurdo Station (78° N), Antarctica, on 9 September 1988 which indicate that the cloud particles are directly involved in ozone depletion in this region. The reductions in ozone appear to be correlated with high concentrations of smaller particles, of about 0.2 micrometre radius, which dominate the surface area density in the cloud. The observations suggest a high degree of spatial inhomogeneity of free chlorine, associated with lower stratospheric clouds, and are important in understanding ozone depletion in this region.

Instruments used in the balloon flights included a temperature and electrochemical ozone sensor of high vertical resolution[3], and an individual particle optical counter similar to types used previously in Antarctica[5] but with an air-sample flow rate about 13 times higher ($\sim 200\ cm^{-3}\ s^{-1}$) so as to resolve the low concentrations ($\sim 10^{-3}\ cm^{-3}$) associated with ice crystal formation. The latter instrument measured in seven size ranges, that is, for radii $r \geq 0.20$, 0.25, 0.30, 1.0, 2.0, 3.0 and 5.0 μm, for spherical particles or for slightly non-spherical particles of equivalent volume[5].

Although most flights reached the 30-km altitude region, we concentrate here on the 10–20-km region investigated on 9 September 1988, for which Fig. 1 shows the temperature and ozone data observed. Also shown for comparison are data obtained on 4 September, which are typical of profiles observed before this time. On 9 September the region between 10 and

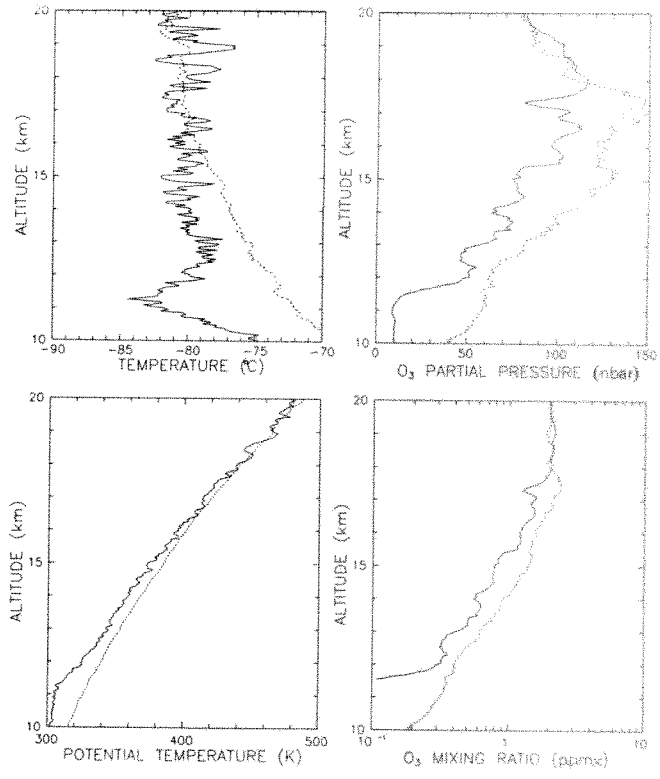

Fig. 1 A comparison of temperature, ozone partial pressure, potential temperature and ozone mixing-ratio profiles measured between 10 and 20 km at McMurdo Station on 4 (dashed line) and 9 (solid line) September 1988.

~11.5 km (an unusually high tropopause) is well mixed and appears to be associated with upward motion; it was in this region that particles with $r \geq 5.0$ μm, presumably comprising water ice crystals, were observed. Above this region, the temperature data indicate a high degree of wave-like stratification with a wavelength of a few hundred metres and an apparent growth in wave amplitude with altitude. The growth rate is consistent with non-dissipative wave propagation, which would double the amplitude between 12 and 20 km.

Reductions in ozone partial pressure at about 12.7, 14.1, 15, 16 and 17.2 km appear similar to those arising from vertical motions, but this is not borne out by the temperature data, as indicated by the potential temperature and ozone mixing-ratio profiles in Fig. 1. Although there exist regions of constant ozone mixing ratio on 9 September, these appear to be unrelated to vertical mixing, because the potential temperature does not show corresponding regions of constancy, as observed in Antarctic mountain-lee-wave events[4]. The region of ice crystal formation on 9 September (10–11.5 km) does show constant potential temperature, associated with cooling of the air parcel by an adiabatic lifting process. The low ozone concentrations in this region are typical of upper-tropospheric values.

The particle measurements made on 9 September are central to an interpretation of the ozone data. Figure 2 shows the 10–20-km profiles of three size ranges, $r \geq 0.20$, 1.0 and 5.0 μm, for 9 September, compared with data obtained with an identical instrument five days earlier. The data for $r \geq 0.20$ μm on 4 September indicate a normal sulphate layer and normal absence of larger particles, as seen in 1986 and 1987[5], except at ~18 km, where there appears to be a slightly enhanced small-particle layer. In contrast, the 9 September profiles are highly enhanced between 11.5 and 17.2 km and between 19 and 20 km; the concentration for $r \geq 0.20$ μm is about 10 times greater than normal at ~12 km. The observations were verified during parachute descent.

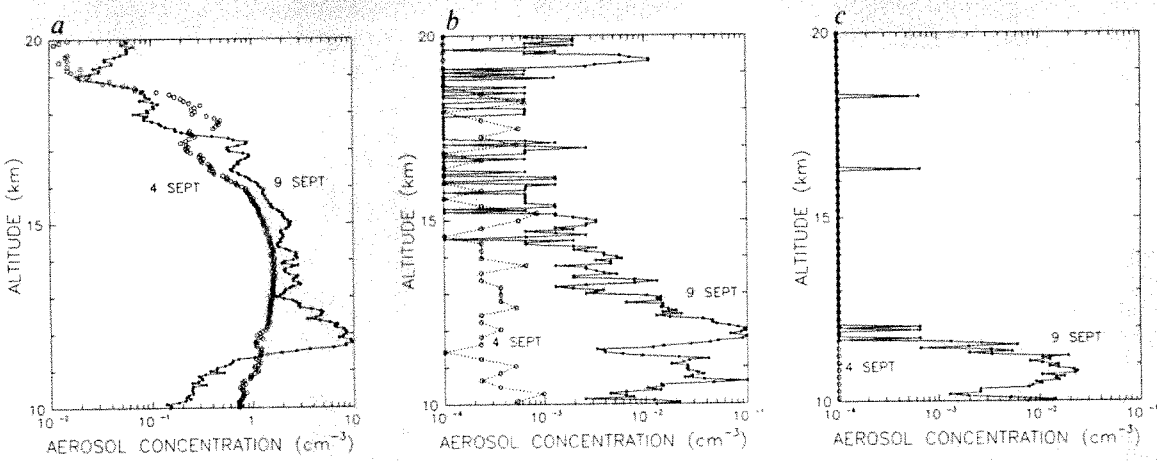

Fig. 2 Aerosol profiles for radii greater than 0.20 (*a*), 1.0 (*b*) and 5.0 (*c*) μm measured between 10 and 20 km at McMurdo Station on 9 September 1988 compared with those measured under non-enhanced conditions on 4 September.

The total aerosol concentration, as observed with a condensation-nuclei ($r \geq 0.01$ μm) counter on 6 and 14 September, was ~20 cm^{-3} at 12 km, so it appears that about half of the available condensation sites grew to sizes larger than 0.20 μm at this altitude on 9 September. The unusual absence of small particles in the 10–11.5-km region is probably associated with attachment to ice crystals in the $r \geq 5.0$-μm layer at this altitude (see Fig. 2). The 1.0-μm profile in Fig. 2 indicates that at 11 km about one half of these particles have radii greater than 5 μm whereas above this altitude (11.5–13 km) all of these particles have radii less than 5 μm and, as the $r \geq 2.0$-μm profile indicates, are essentially all between 1 and 2 μm. Because there is insufficient sulphuric acid vapour to constitute the mass in the 1–2-μm particles observed at 11.5–13 km, and because it is probably too warm (−78 to −79 °C) at this altitude to condense water, these particles may represent the condensation of nitric acid trihydrate (NAT), which can form at temperatures about 7 °C higher than the water ice point[6]. However, if sufficient water vapour was mixed up into the 10–11.5-km region to form water ice at −80 to −84 °C, as indicated by the 5.0-μm data, it is possible that enough water vapour was present at 11.5–13 km to initiate water condensation at these higher temperatures. The lack of vertical mixing above 11.5 km and the abrupt reduction in particle production at this altitude, as indicated by the minimum in 1.0-μm concentration, makes the latter unlikely. Figure 2 also indicates an $r \geq 1.0$-μm layer between 19 and 20 km (another layer was observed between 21 and 22 km) where it would be too dry (frost point ~−90 °C (ref. 7)) for water ice particles to form at the observed temperature of ~−80 °C. Thus, the most reasonable conclusion is that the enhanced aerosol observed throughout most of the stratosphere on 9 September was composed of NAT.

Figure 3 shows the size distributions for the 11- and 12-km data (0.5-km averages) on 9 September, compared with the 4 September size distribution of the normal sulphate layer at 12 km. The enhanced distributions of 9 September are bimodal. At 11 km, the ice crystals have suppressed the sulphate distribution through attachment. Fitting a log-normal size distribution to the large-particle ($r \geq 1.0$ μm) mode at 11 km gives a mode radius of 5 μm, a distribution width of 1.5 and a total concentration of 0.03 cm^{-3}, which results in a surface area density of 13 $\mu m^2\ cm^{-3}$ and a mass mixing ratio, for water composition, of 0.10 p.p.m., which is only a small fraction of the 2–3 p.p.m. of water vapour available[7].

For the bimodal distribution at 12 km, the small-particle mode can be characterized by a mode radius of 0.19 μm, a width of 1.28 and a total concentration of 20 cm^{-3}, which results in a mass mixing ratio of 3.3 parts per 10^9 (p.p.b.). The large-particle mode at 12 km has corresponding values of 0.83 μm, 1.34, 0.3 cm^{-3} and 4.6 p.p.b. Combining the mass in the two modes gives 7.9 p.p.b., which, assuming an NAT composition, implies a value of 2 p.p.b. by volume of HNO_3. Thus the particles in these clouds have probably incorporated a sizeable fraction of the available HNO_3 vapour. Although there is more mass in the large-particle mode at 12 km, the small-particle mode dominates the surface area density (3.1 $\mu m^2\ cm^{-3}$ and 10.2 $\mu m^2\ cm^{-3}$ respectively for the two modes). This suggests that in a typical cloud undergoing particle growth in the lower stratosphere area-dependent phenomena such as heterogeneous chemical reactions are controlled by numerous small particles rather than by a few large particles, in contrast to what has been assumed previously[8]. Thus reductions in ozone owing to heterogeneous chemistry in such clouds should correlate best with the small particle mode.

Figure 4 compares the 10–20-km ozone partial pressure and $r \geq 0.20$-μm aerosol profiles. Negatively correlated layers are apparent at 12.7, 14.1, 15, 16.9 and 17.2 km. Correlations are weak or absent for the 1.0-μm aerosol data, as expected from surface-area considerations. To account for this correlation by quasi-horizontal advection, as has been observed in the past[6], would require a source region unusually rich in particles and poor in ozone. As these observations were made near the centre of the vortex, such ozone depletion cannot be explained by assuming that we are observing low-latitude air; furthermore such enhanced particle concentrations have never been observed in the stratosphere except after major volcanic eruptions and i

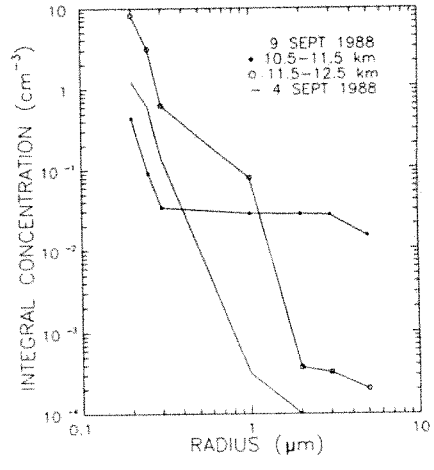

Fig. 3 Integral size distributions for the particle layers observed in polar stratospheric clouds on 9 September and in the undisturbed sulphate layer at 12 km on 4 September.

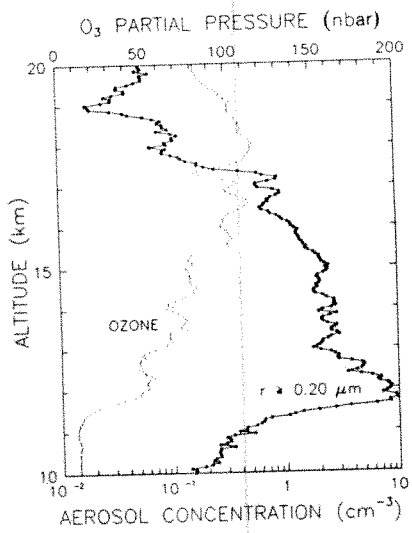

Fig. 4 Ozone partial pressure and $r \geq 0.20$-μm aerosol profiles between 10 and 20 km at McMurdo Station on 9 September 1988. Note the inverse correlations at 12.7, 14.1, 15, 16.9 and 17.2 km.

conjunction with very cold regions of the Antarctic polar vortex[5]. No such eruptions were reported at this time, and particle concentrations had returned to normal values when next measured on 27 September.

These measurements thus constitute the first evidence that ozone is reduced directly within polar stratospheric clouds, in contrast to the comparatively loose correlation assumed previously. This explains why ozone depletion takes place in the lower stratosphere, where the abundance of free chlorine may appear to be too low for conventional ozone depletion chemistry to take place. Temperatures low enough for NAT to exist are present in the lower stratosphere well into October, thus prolonging ozone depletion in this region as observed.

The close anticorrelation with aerosol surface area suggests a direct process whereby ozone molecules are destroyed following collision with particles. Such a process, however, could continue through the winter. As depletion does not begin until early September, photochemistry is clearly involved. It is possible that in the lower stratosphere active chlorine exists only within the denser clouds, in which nitric acid has effectively been removed, whereas above 17 km it exists more uniformly. This may be related to the occurrence of apparently more extensive haze- or veil-type polar stratospheric clouds at higher altitudes, compared to the denser, more inhomogeneous clouds in the lower stratosphere[3,5,7-9]. It would suggest a process that would result in a high degree of spatial inhomogeneity in the ozone distribution of the lower stratosphere and could contribute to the high degree of ozone layering observed in the Antarctic lower vortex[3,4]. Although most of this structure is believed to be related to ozone emanating from the vortex boundary[4], layering in the Antarctic lower-stratospheric ozone distribution has been observed to some extent everywhere within the vortex[3,4,9-11]. This phenomenon may be more readily observable in years when the QBO is in an easterly phase (for example, 1986 and 1988), during which warmer temperatures result in reduced denitrification during the winter.

Characterization of a new helical smectic liquid crystal

J. W. Goodby, M. A. Waugh, S. M. Stein, E. Chin, R. Pindak & J. S. Patel*

AT&T Bell Laboratories, Murray Hill, New Jersey 07974, USA
* Bell Communications Research, Redbank, New Jersey 07001, USA

The discovery of the first liquid-crystalline material in 1888[1,2] also heralded an age of fascination with chirality and optical activity in ordered fluids. The cholesteric mesophase, which was the first liquid crystal to be found, exhibits form optical activity by virtue of a helical arrangement of its constituent molecules. One hundred years after the discovery of this first liquid crystal, we report the discovery of a new helical smectic liquid crystal, the smectic-A* phase. In this phase the lath-like molecules are arranged in layers with their long axes on average normal to the layer planes. Parallel to the layers there is a helical ordering of the molecules (Fig. 1). We suggest that this phase may be described by a model in which grain boundaries of screw dislocations rotate blocks of layers with respect to each other.

This novel phenomenon was found to occur in an homologous series of ferroelectric liquid crystals, the *R*- and *S*-1-methylheptyl 4′-[(4″-*n*-alkoxyphenyl)propionoyloxy]-biphenyl-4-carboxylates (*n*P1M7). These materials were prepared by the esterification of a variety of 4-*n*-alkoxyphenylpropiolic acids with *R*- or *S*-1-methylheptyl 4′-hydroxybiphenyl-4-carboxylate (ref. 3, and M.A.W. and S.M.S., to be published). The helical A* phase was found in the *n*-tridecyloxy, *n*-tetradecyloxy and *n*-pentadecyloxy homologues, which have the general chemical formula:

and exhibit the phase transitions:

$$\text{Isotropic liquid} \leftrightarrow A^* \leftrightarrow C^* \leftrightarrow S3 \leftrightarrow S4$$

where the new helical phase is denoted as A*, the ferroelectric phase as C* (see Fig. 1)[4], and two further hitherto unclassified helical smectic modifications as S3 and S4 (ref. 5).

Evidence from optical microscopy was obtained for the helical nature of the phase formed first on cooling the isotropic liquid of either the *R*- or the *S*- enantiomers of these esters. For example, in a simple experiment in which the *n*-tetradecyloxy member was sandwiched between clean glass plates, heated to form the isotropic liquid and allowed to cool into the new phase, the phase was found to separate from the liquid in two distinct ways, as shown in Fig. 2*a*. In this photomicrograph the A* phase exhibits two distinct textures, one a platelet texture and the other a Grandjean plane texture[6]. The platelet texture resembles that of Blue Phase I, whereas the Grandjean plane texture appears iridescent and similar to that of the cholesteric phase. As the plane texture nucleates and grows, striations within the texture are seen. These bands possibly correspond to integral multiples of the pitch of the helix of the phase. Subsequent cooling produces a transition to a chiral smectic-C* phase, which exhibits typical banded, focal-conic and iridescent plane

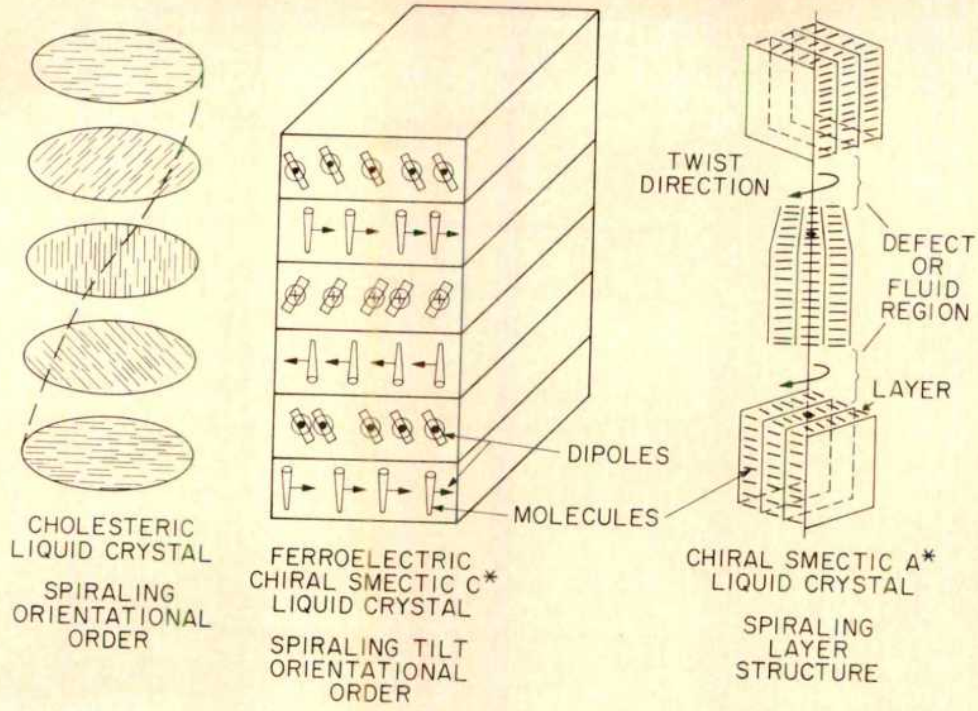

Fig. 1 A pictorial representation of some helical liquid crystal phases, including the cholesteric, the chiral C*, and the chiral A* modifications.

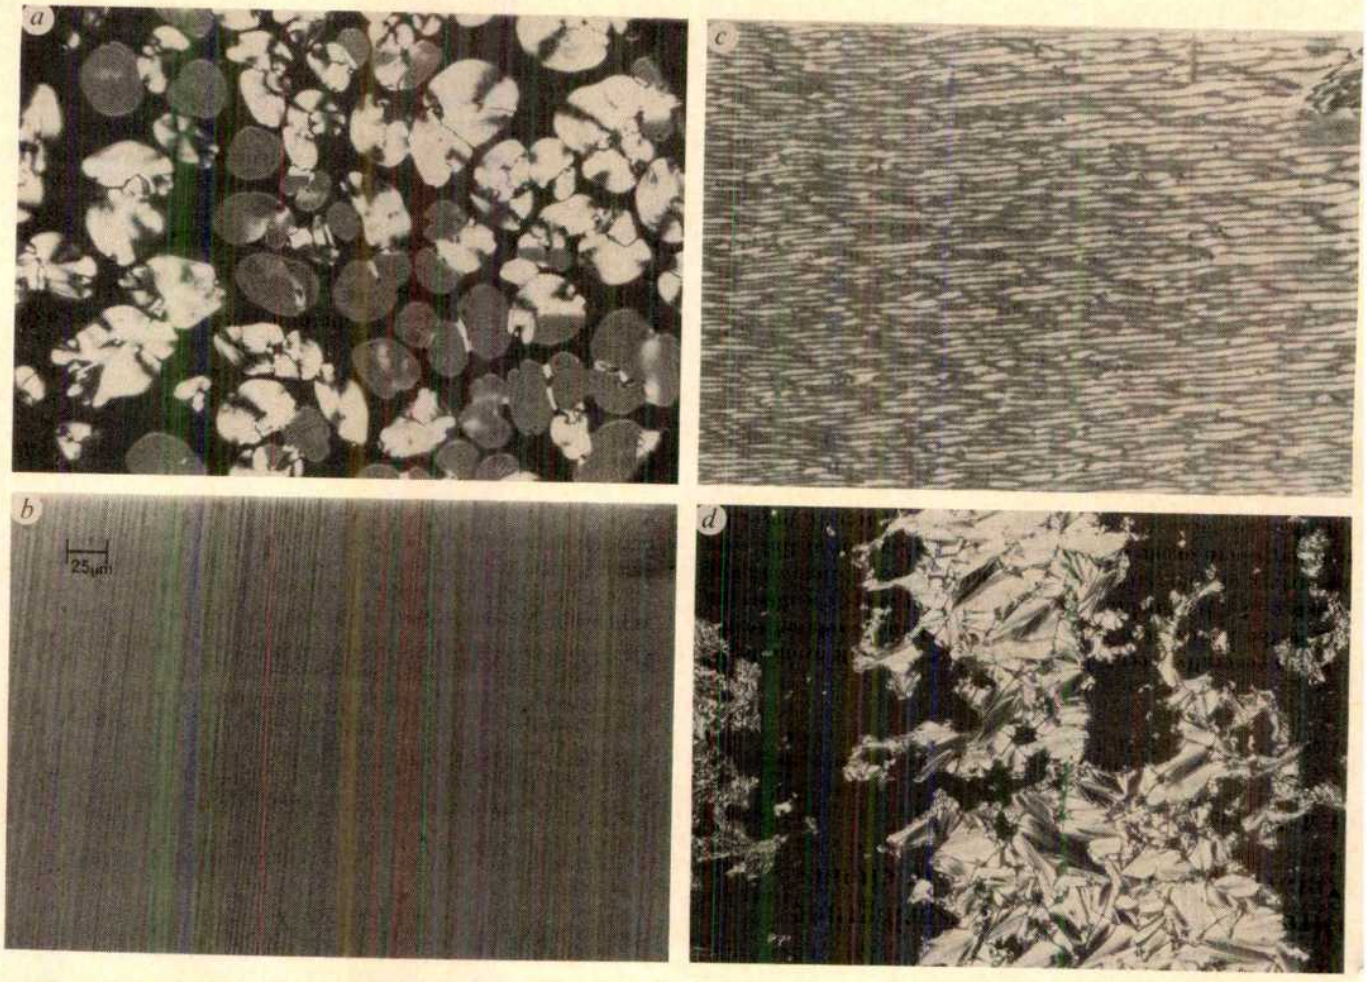

Fig. 2 *a*, The A* phase separating from the isotropic liquid (×100). *b*, An aligned texture of the C* phase of the *R*-tetradecyloxy homologue. The vertical lines are related to the pitch of the helix of the phase. *c*, The same area as in *b*, but the material is now in the A* phase, and the pitch bands are now orientated horizontally. In both photomicrographs, the material was confined in a cell constructed of conducting glass. The plate separation was 10 μm. A holding voltage of 5 V d.c. was applied to the cell in both cases (×100). *d*, A contact preparation between the *R*- and *S*-enantiomers of 1-methylheptyl 4'-[(4"-*n*-tetradecyloxyphenyl) propionoyloxy]-biphenyl-4-carboxylate. The centre of the specimen has the texture of the A phase of the racemic modification, whereas the outer regions have the A* texture of the enantiomers (×100).

textures. The striations on the focal-conic domains, which mirror the positions of the molecular layers, are due to helical pitch bands and dechiralization lines[7]. On cooling through the A* → C* transition, the focal-conic domains of the C* phase grow in the regions of the specimen where the Grandjean texture of the A* phase was present initially. For the Grandjean texture the axis of the helix of the A* phase is normal to the glass plates, but in the focal-conic domains of the C* phase it can be seen, from the pitch bands and dechiralization lines, that the helical axis is approximately parallel to the glass. Thus, if the integrity of the layers is maintained through the phase transition, the helical axes in the A* and C* phases must be mutually perpendicular.

The position of the helical axes in the two phases was confirmed in a separate experiment, in which the material was aligned in a cell constructed from electrically conducting glass. The internal surfaces of the cell were unidirectionally buffed to create sites for planar, homogeneous growth of the liquid crystal[8,9]. Epitaxial growth from the liquid resulted in the formation of a Grandjean plane texture. Rotation between crossed polarizers produced no extinction, indicating that the molecules were symmetrically disposed to the viewing direction. This property is typical of a helical structure[9]. As expected, cooling into the smectic-C* phase produced a focal-conic texture[10]. However, even though the molecules were confined by the aligning agent to lie parallel to the plates of the cell, there was a random orientation of the focal-conic domains. This means that molecules did not lie in a preferred direction within the plane of the cell. This texture is similar to that obtained when the C* phase is formed directly from the cholesteric phase[9].

Application of an electric field to the specimen in the ferroelectric C* phase, for conditions close to the C* → A* transition, produced an aligned sample[9]. In the presence of a small holding d.c. voltage (1 volt per micrometre of cell thickness) dechiralization lines were observed. These lines were oriented at approximately the tilt angle of the C* phase to the buffing direction, and were parallel to the molecular layers (Fig. 2*b*). The axis of the helix is therefore in the plane of the cell and perpendicular to the layers. On heating the specimen into the A* phase, the lines became oriented approximately perpendicular to those in the preceding C* phase, thereby giving a texture reminiscent of the cholesteric finger-print texture (Fig. 2*c*). This confirms that the helical axes in the two phases are oriented perpendicularly. Thus, the helix lies in the plane of the layers in the A* phase. The two relevant textures are shown in Fig. 2*b* and *c*, in which are displayed equivalent areas for each phase. When the holding voltage is relaxed, the A* phase reverts to a plane texture.

For the purposes of phase classification, the new A* phase can be clearly distinguished from the cholesteric phase in two different experiments. One of these examines the properties of the racemic modifications of these compounds and the other probes the structure of the phase by X-ray diffraction.

The racemic modifications of these materials can be obtained either by synthesis from racemic starting materials or by mixing the *R*- and *S*-enantiomers. In the first case the synthetically prepared material was found to exhibit normal A and C phases. In the second, the liquids of the *R*- and *S*-enantiomers can be sandwiched between glass plates as before and cooled into their liquid-crystalline phases[11] (Fig. 2*d*). At the junction of the two materials, a racemic modification appears. The proportions of enantiomers in the mixture change with distance from this interface so as to eventually give one or other of the pure enantiomers. Thus a concentration gradient can be observed in the microscope, and the phase changes that occur with varying concentration can be studied as a function of temperature. At the interface, the racemic mixture exhibits the A phase, which was identified from its focal-conic texture. Moving away from the interface there is a continuous change in texture from a homeotropic to a platelet texture as the A* phase appears (Fig. 2*d*). As there are no abrupt changes in the texture to indicate

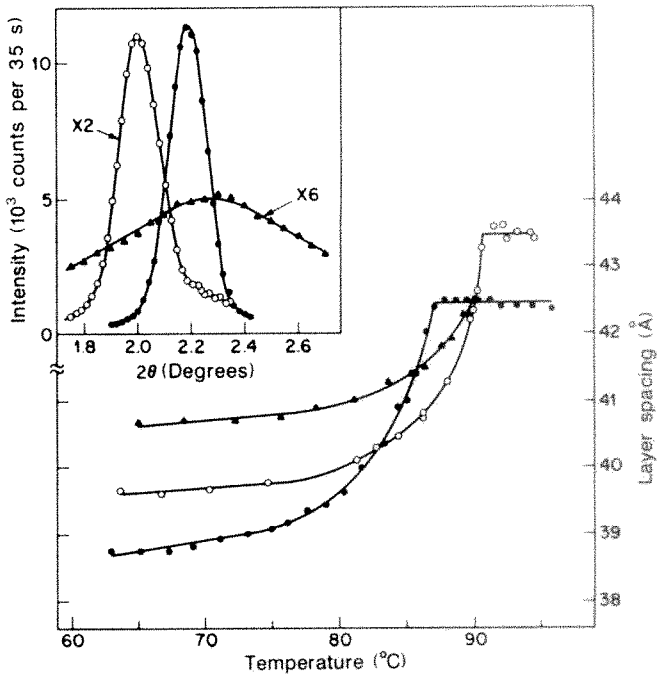

Fig. 3 The temperature dependence of the layer spacing for the $n = 12$ (filled circles), 14 (open circles) and 16 (triangles) *R*-enantiomers. The inset shows scans through the layer peak for the $n = 14$ enantiomer at temperatures within the C*-phase (closed circles; $T = 82.8$ °C), the A*-phase (open circles; $T = 93.3$ °C), and (just into) the isotropic-phase stability fields (triangles; $T = 97.4$ °C).

a phase change, this observation suggests that the A and A* phases are continuously miscible[12], thereby classifying the helical phase as A. It is also interesting to note that the A phase formed at the interface of the racemic mixture has a higher transition temperature than the surrounding corresponding pure enantiomers. Thus, the A phase of the racemate appears to be more stable than the A* phase of the enantiomers. Cooling resulted in a transition to the respective C and C* phases.

Further evidence for distinguishing the A* phase from a cholesteric phase was obtained from X-ray diffraction using an 18-kW rotating-anode-based spectrometer. For this study, unaligned samples of the *R*-*n*-dodecyloxy, *R*-*n*-tetradecyloxy and *R*-*n*-hexadecyloxy ($n = 12$, 14, 16) homologues were prepared in 1-mm glass capillaries. A vertically bent pyrolytic graphite (002) crystal was used to focus Cu Kα X-rays to a 0.5×2.0 mm spot on the sample. The scattered radiation was then analysed using slits and a flat pyrolytic graphite crystal. This defined an instrumental resolution of 0.01 Å^{-1} full width at half maximum in the scan direction, and 0.02 Å^{-1} transverse to the scattering plane.

The primary X-ray study consisted of 2θ scans through the smectic layer peak. The temperature dependence of the layer spacing for the three enantiomers is shown in Fig. 3. The layer spacing for each of the enantiomers increases continuously on heating and, for the *n*-dodecyloxy and *n*-tetradecyloxy members, saturates in the A* phase at a relatively constant value. The lamellar spacing was found to be commensurate with the length of a fully extended molecule.

The inset of Fig. 3 shows layer peak scans taken within the C*, A* and isotropic phases of the *R*-*n*-tetradecyloxy homologue. Within instrumental resolution, the layer peak widths for the C* and A* phases are similar, and the integrated intensities in these peaks differ by only a factor of two. This implies that the A* layer correlations extend a minimum distance of ten layers, thereby establishing smectic layering as a key structural element of this phase. At a temperature just above the A* → isotropic-liquid transition, a diffuse layer peak is seen with a peak position that is comparable to the layer peak position measured well within the temperature range of the C*

phase. The nature of this observation will be discussed briefly later.

Thus, the qualitative model that emerges for this new phase is one in which the elongated molecules are arranged in loosely ordered layers with their long axes either normal to or only slightly tilted with respect to the layer planes. In the direction of the layer planes there is a twist in the parallel orientation of the molecules. This twist can be effected either by defects, such as screw dislocations, between short sections of the A phase, or by cholesteric liquid-like regions separating larger smectic-A domains, as shown in Fig. 1. The full structural details of this phase are now being studied by high-resolution X-ray diffraction from aligned samples and by freeze-fracture studies. The results obtained from these investigations will be reported soon.

Finally, we note that de Gennes[13] has predicted that, just as magnetic flux can penetrate Type II superconductors in a lattice of vortices, twist or bend distortions can be incorporated into a layered A structure by the presence of an array of screw or edge dislocations. A model for such an array was proposed recently by Renn and Lubensky[14]. With reference to the structure of the A* phase shown in Fig. 1, their model specifies that grain boundaries of screw dislocations are responsible for rotating the individual 'blocks' of the A* layers with respect to each other. They call the resultant phase a twist-grain-boundary (TGB) phase, and predict that it can occur between the cholesteric and the A phase in a manner similar to the occurrence of the Abrikosov flux-lattice phase between normal and superconducting phases[15]. Renn and Lubensky established that the requirement for this intermediate phase to occur is that the Ginzburg parameter, which is equal to the ratio of the twist penetration length (λ_T) to the smectic-A correlation length (ξ), must be greater than $1/\sqrt{2}$.

Consequently, the TGB phase is a feasible model for the A* phase, for the following reasons. First, the X-ray scattering pattern predicted for the TGB phase is consistent with our X-ray measurements on the A* phase. Second, the model predicts a helical structure with the helical axis parallel to the smectic layers, which is consistent with our optical experiments. Finally, we observe the A* phase in the vicinity of an A→C* transition, where the A phase is stable over a short temperature range. At such a transition, λ_T diverges, resulting in a large value for the Ginzberg parameter, as required by the theory (R. B. Meyer, personal communication). Assuming that the TGB phase is a viable model for the A* phase, we can explore the possible implications of this phenomenon still further. In particular, we can speculate on the nature of the effect observed near to the clearing point in the isotropic liquid. For the superconducting flux lattice it has been proposed[16] and observed[17] that the vortex lattice can disorder into an entangled or disentangled fluid of vortices. We suggest that a similar disordering of the regular array of screw dislocations in the TGB phase may be the mechanism responsible for the occurrence of the effect observed in the isotropic liquid at a temperature just above the transition from the A* phase.

Disequilibrium of Holocene sediment yield in glaciated British Columbia

Michael Church & Olav Slaymaker

Department of Geography, University of British Columbia, Vancouver, British Columbia, Canada V6T 1W5

It is generally supposed that specific sediment yield—the quantity of sediment passing a monitored river cross-section per unit area drained upstream of that section—declines as the area drained increases[1–3]. Part of the sediment mobilized from the land surface is supposed to go back into storage at field edges, and on footslopes and floodplains. In contrast, we show here that data from British Columbian rivers reveal a pattern of increasing specific sediment yield at all spatial scales up to 3×10^4 km^2. This results from the dominance of secondary remobilization of Quaternary sediments along river valleys over primary denudation of the land surface. The result controverts the conventional model which has been derived from studies of small, highly disturbed agricultural catchments. The rivers are still responding to the last glaciation, giving a landscape relaxation time greater than 10 kyr. This holds profound implications for geomorphological theory and for studies of erosion.

Happ and others[4–6] have shown that specific sediment yield presently increases downstream in the south-eastern United States, which they explained in terms of remobilization of sediment eroded from uplands during the first two centuries of European agrarian settlement. Schumm[7] has asserted that such a complex response to episodes of upland erosion is the usual pattern of river-basin development, but apart from a speculation by Meade[8] that the response in this region may persist for centuries, little has been said about the timescales of adjustment of the fluvial landscape to perturbations in sediment supply, nor has the conventional model been tested critically in natural landscapes.

Our main data resource is the archive of suspended sediment loads obtained by the Water Survey of Canada since 1965. These data (Fig. 1) have been discussed at length elsewhere[9,10]. Here we emphasize only that they represent contemporary fluvial sediment transfers in British Columbian rivers. Bedload transport, which is not normally measured, accounts for a comparatively small proportion of the total load[11]. Although solutes may be significant, they do not alter the pattern presented in Fig. 1[9]. The data have been augmented by results from research studies of small drainage basins[9,12], which allow us to extend the domain of drainage areas by two orders of magnitude. We have classified basins according to whether (1) they contain contemporary glaciers, (2) they contain large lakes or reservoirs, (3) they have been disturbed by human land use, including mining and contemporaneous clearance of more than 5 per cent of the forest, and (4) they are undisturbed. No basin has a significant proportion (>5%) of arable land.

The relation of sediment yield to drainage area (Fig. 1) is complex, but a clear trend emerges for basins that are classified as undisturbed. Only three such basins plot outside this trend. Specific sediment yield increases through all areas up to about 3×10^4 km^2. Between 40 km^2 and 10^4 km^2, specific yield is approximately proportional to (area)$^{0.6}$, implying a near-linear increase in sediment yield downstream. The local range of the main trend is between about one-half and one order of magnitude in yield: detailed examination of the data[10] indicates that variable Quaternary and bedrock geology is the cause. There is no systematic association, however, between rock type and topography to explain the overall trend, which is replicated within individual major drainage basins.

On the evidence of Fig. 1, primary denudation, indicated by sediment yield in the smallest basins, is more than an order of

h = mean bank height; M = mean meander migration rate on bend axis. Data from refs 14, 15.
* Calculated as 1.5 $(h-2)M/2$; 1.5 (Mg m^{-3}) is the assumed bulk density of bank material, $h-2$ adjusts for bed material in the lower bank, and $M/2$ gives the average erosion rate assuming linear variation around the bend.
† From equations in the text; equation for mainstream length is $L = 1.2\,A_d^{0.6}$
‡ Some of these rivers are identical with ones in our study, but the places of measurement are different.

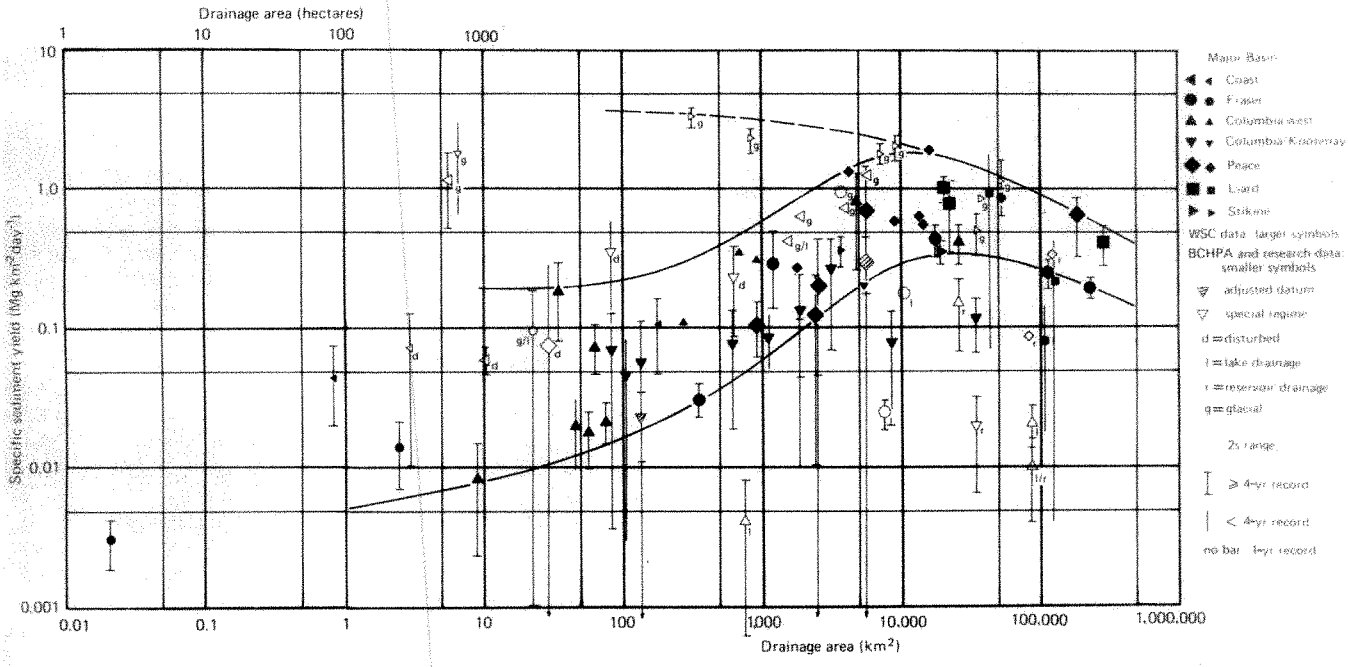

Fig. 1 Specific sediment yield as a function of drainage area for fluvial suspended-sediment-transport records in British Columbian rivers. Closed symbols indicate data for the natural landscape; open symbols indicate yields influenced by natural or human disturbance factors. The main trend of undisturbed yields was sketched by eye. See ref. 10 for a detailed discussion of the data.

magnitude smaller than yield rates in medium to large basins. The latter include a large component arising from secondary remobilization of recent sediments[13]. One must conclude that most of the sediment transported in British Columbian rivers is recruited from the riverbanks and immediate valley-sides. Much of it is derived from the erosion of Quaternary sediments in the valleys and from landsliding of incompetent valley walls.

Thus, the rivers are degrading through valley fill deposits. This is qualitatively evident by the widespread occurrence of Holocene terraces and entrenched trunk streams. We are able to make a quantitative test of our conclusion using data on rates of meander migration obtained by Hickin and Nanson[14,15]. Assuming a linear relation between specific sediment yield and mainstream length (L) for the rising limb of our trend, total sediment yield Y is proportional to $A_d L$, where A_d is drainage area, so that dY/d$L \propto A_d$. The upper and lower envelopes of our plot are then given approximately by dY/d$L = 36 \times 10^{-4}\,A_d$ and dY/d$L = 6.5 \times 10^{-4}\,A_d$, with the coefficients appropriate for units of Mg m^{-1} yr^{-1}. dY/dL is the rate of increase in net erosion downstream, or the net rate of bank erosion if the sediment comes from the stream banks. Table 1 shows that the measurements of Hickin and Nanson generally fall within the range predicted by our analysis. All the results demonstrate that riverbank erosion rates are sufficient to support our interpretation of the regional trend of increasing sediment yield.

The conventional model, in which specific sediment yield decreases with basin area, was derived mainly with reference to intensely cultivated regions in which the land surface is highly disturbed and exposed to erosion[1,2], so that headwater sediment supply is comparatively unlimited. The sediment yield pattern observed in the natural landscape of British Columbia is more consistent with common notions of pristine headwater streams—particularly in mountains—and sediment-laden trunk rivers. A pattern of sediment yield similar to that observed here has been

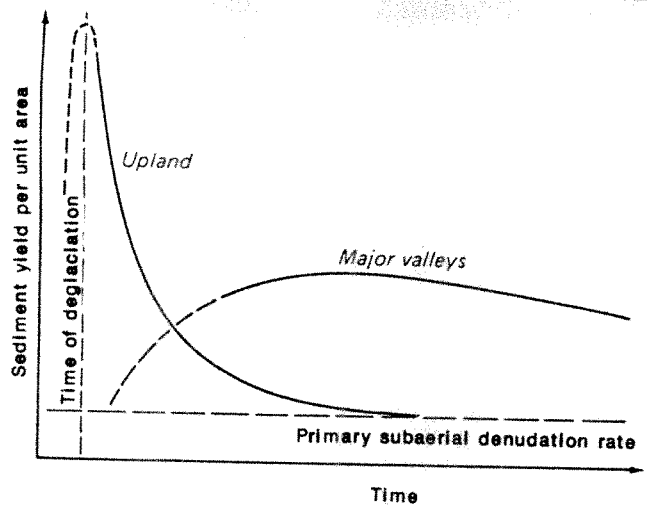

Fig. 2 The paraglacial sedimentation cycle[17], modified to indicate the effect of spatial scale upon the temporal pattern of sediment yield. The time axis spans approximately 10,000 yr.

reported on the Canadian prairies[16], with similar rationalization.

The major rivers are still redistributing sediment that was delivered to the valleys by glacial events more than 10 kyr ago. The transfer and disposition of this material has been termed a 'paraglacial cycle' of sedimentation[17]. Originally, evidence of a paraglacial cycle was adduced from outwash deposits and alluvial fans present in the major valleys, and a relaxation time of a few thousand years was inferred from chronostratigraphic markers in the fans. It is now apparent that this timescale is relevant only for the restricted spatial scale of the upland basins that deliver sediment to the fans. An extended paraglacial cycle (Fig. 2) may be said to dominate still in the larger basins. The trend of specific sediment yield in the largest basins ($>3\times10^4\,km^2$) is consistent with that of contemporary glacierized basins—the most disturbed basins in the region—and conforms approximately with the conventional model. The largest basins are still responding to glaciation. The timescale for ultimate dissipation of this phenomenon appears to be many tens of thousands of years.

It has been supposed for more than 30 years that landscapes adapt so as to reach equilibrium, in some sense, with the imposed environment[18,19], which, for stream systems, implies the hydroclimate[3]. Sediment yield is thereby supposed to be the consequence of erosion from the surface of the land and is supposed to reflect the denudation rate for the prevailing climate and regional geology. This view has been challenged[20] on the basis of observations in the south-eastern United States[4,5]; it certainly is not true at any resolved scale in British Columbia. Fluvial sediment yield at all scales above 1 km^2 remains a consequence of the extraordinary glacial events of the Quaternary Period, rather than of Holocene erosion of the land surface. The results presented here confirm Schumm's contention[7] that fluvial sedimentation does not reflect contemporary erosion of the land surface at any timescale below that for significant evolution of the entire land mass, which is of the order of several ten thousands of years. The natural landscape of British Columbia is imprisoned in its history.

Circadian rhythm and light regulate opsin mRNA in rod photoreceptors

Juan I. Korenbrot* & Russell D. Fernald†

*Departments of Physiology and Biochemistry, School of Medicine, University of California, San Francisco, California 94143 USA
† Institute of Neuroscience, University of Oregon, Eugene, Oregon 97403, USA

Disk membranes in the outer segment of rod photoreceptors are continuously renewed, being assembled at the outer segment base, displaced outward by new disks and eventually shed at the tip[1]. In lower vertebrates, disk assembly occurs with a diurnal rhythm with 2–4% of the outer segment length produced daily[2,3]. We have discovered that in toad and fish retinas the level of mRNA for opsin, the most abundant protein in rod disks[4], fluctuates with a daily rhythm and is regulated both by light and by a circadian oscillator[5]. The mRNA level rises before light onset, remains high during the light phase of a diurnal cycle and decreases four to tenfold during the dark phase. In constant darkness, mRNA elevation occurs during subjective daytime. At night, rod opsin mRNA can be elevated by exposure to light.

The level of rod opsin mRNA was measured by hybridization of an opsin antisense RNA probe to blots of total RNA isolated from the retinas of toads (*Bufo marinus*) and fish (*Haplochromis burtoni*). The opsin RNA probe was synthesized *in vitro* using a fragment subcloned from the bovine rod opsin cDNA (Fig. 1). This fragment is highly conserved in both human[6] and *Drosophila melanogaster*[7] rod opsin, but badly conserved in the rod opsin homologous proteins: β-adrenergic receptor[8] and muscarinic acetylcholine receptor[9]. The use of rod opsin probes across species is also justified by the homology between the visual pigment genes in species ranging from archibacteria to mammals[10].

The specificity of our antisense opsin RNA probe, FH97, in toad and fish tissue was verified by hybridization both to blots of total retinal RNA and *in situ*, to retinal sections. At high stringency hybridization (10–12 °C below the calculated transition temperature for the hybrid assuming perfect nucleotide matching[11]) a single band was detected in autoradiograms of both toad and fish RNA blots (Fig. 1*a*). In toad RNA blots, a fainter, smaller band was occasionally detected. The labelled RNA was 2.85 kilobase (kb) in the toad and 1.4 kb in the fish, suggesting that in toads, but not fish, the rod opsin mRNA includes an untranslated sequence. *In situ* hybridization at identical stringency revealed that the reactive RNA was located exclusively over the myoid region of the photoreceptor inner segments (Fig. 1*b*, *c*).

To determine whether both rod and cone-opsin species were detected by FH97, we used *in situ* hybridization of dark adapted fish retina in which the cone inner segments are displaced relative

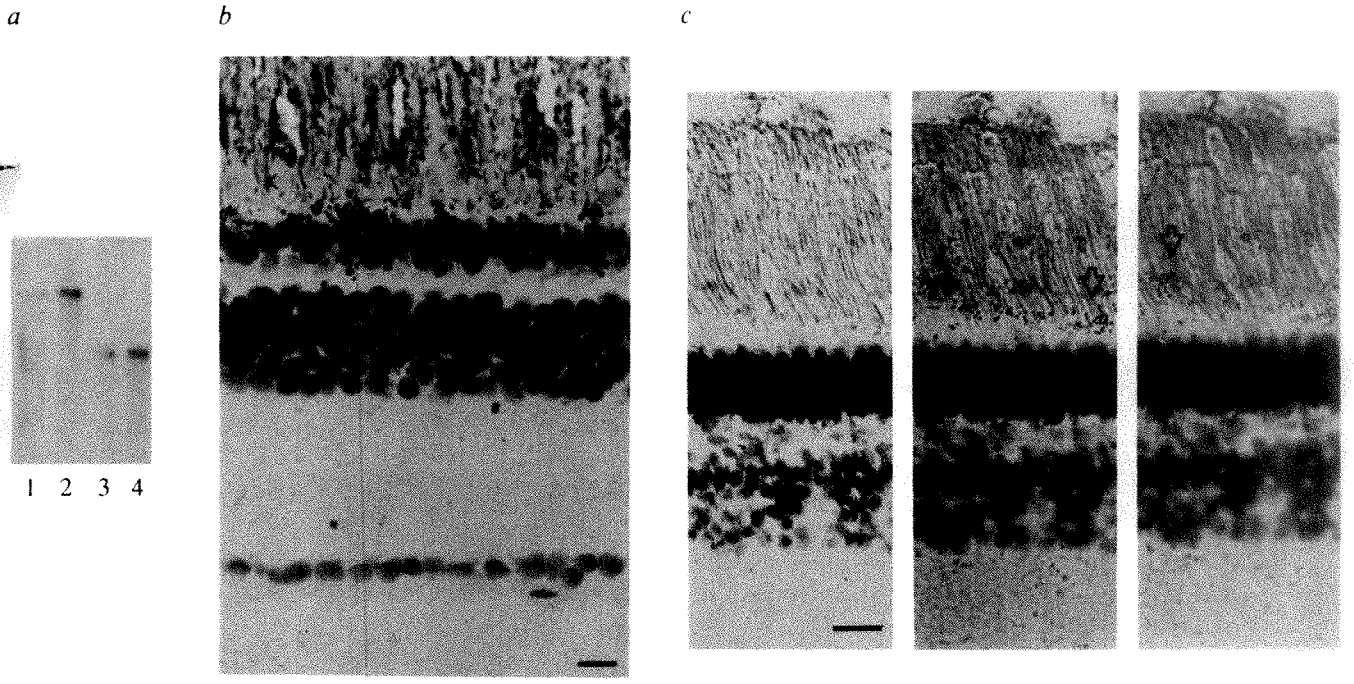

Fig. 1 *a*, Identification of rod opsin mRNA in total retinal RNA blots of toad, *Bufo m.*, and fish, *Haplochromis b.* At high stringency, only a single band was detected in autoradiograms from both toad (lane 1, 4 μg; lane 2, 8 μg) and fish (lane 3, 5 μg, lane 4, 10 μg). *b*, *c*, *In situ* hybridization of retinal sections from toad (*b*) and fish (*c*) with ^{35}S-labelled FH97 antisense mRNA probe. Hybridization was conducted at the same stringency used to probe the RNA blot in *a*. *b*, A light-microscope autoradiograph of a light-adapted toad retina. Autoradiographic grains are exclusively localized over the inner segments of the photoreceeptors. *c*, Three photomicrographs of the same field from a dark-adapted fish retina. The left micrograph is focused on the cell bodies, whereas the middle and right micrographs are focused at two different depths within the autoradiographic emulsion. In the middle micrograph, the autoradiographic grains (arrow) are seen distributed over the inner segments of rods. In the right micrograph, the grains (arrow) are localized in discrete groups over the inner segments of cones displaced from the rod inner segments. Scale bar, 10 μm.

Methods. *a*, Retinas and adhering pigment epithelium were isolated, frozen and maintained in liquid nitrogen until processed. Total RNA was isolated and purified[19], separated by size in a denaturing gel (formaldehyde) and transferred to Nylon 66 membranes[20]. Blots were prehybridized at 55 °C in 50% formamide, 5 × SSC, 5 × Denhardt's, 1% sarcosyl, 5 mM EDTA, 0.1 mg ml^{-1} yeast tRNA, 0.1 mg ml^{-1} sonicated salmon sperm DNA. Hybridization was at 55 °C for 20 h in the same solution with 10^6 c.p.m. ml^{-1} of ^{32}P-labelled probe. Final stringency of hybridizataion was obtained by washing at 75 °C in 0.2 × SSC with 2.5 mM sodium pyrophosphate, 10 mM EDTA and 0.1% sarcosyl. The opsin antisense mRNA probe (FH97) was synthesized *in vitro* (pGEM4, Promega) from a fragment of bovine rod opsin cDNA obtained by *Fnu*DII–*Hin*fI digestion (nucleotides 544–641) of a full cDNA clone[10]. This 97 base pair (bp) fragment (FH97), codes for amino acids in the intra-membrane helix V and the loop between helices IV and V on the intra-discal surface of rod opsin[21] *b*, *c*, Eyes were fixed by immersion for 50 min in 4% paraformaldehyde, 0.1% glutaraldehyde in 0.1 M phosphate buffer, *p*H7.4 followed by 4% paraformaldehyde in the same buffer for 15 min. Tissue was embedded in diethylene glycol distearate (DGD)[22]. Retinal sections (3 μm thick) were placed on poly-L-lysine (0.1 mg ml^{-1}) coated slides and DGD removed. Sections were rehydrated, acetylated[23] and prehybridized for 1 h at 45 °C in 60% formamide, 1 × Denhardts', 75 mM NaCl, 5 mM Tris *p*H 8, 2.5 mM sodium pyrophosphate, 5 mM EDTA, 0.1 mg ml^{-1} yeast tRNA, 0.1 mg ml^{-1} denatured salmon sperm DNA. The sections were hybridized for 6 h at 45 °C with ^{35}S-labelled antisense RNA FH97 added to the same medium in the presence of 100 mM dithiothreitol. After hybridization, sections were washed with 500 mM NaCl, 30 mM Tris *p*H 8 at 45 °C, incubated with RNAase A in this solution at 37 °C for 30 min and washed extensively in 500 mM NaCl, 30 mM Tris *p*H 8 at 45 °C. Slides were coated with NTB-2 emulsion (Kodak), exposed at 4 °C, developed and stained with cresyl violet.

to those of the rods[12] and found that the probe labelled both rod and cone inner segments (Fig. 1*c*). Although FH97 antisense RNA probe could identify both rod and cone mRNA, in blots of total retinal RNA rod opsin mRNA is almost certainly more abundant than cone opsin mRNA. In toads, for example, there are threefold more rods than cones and each rod outer segment is about 30-fold larger than that of a cone. If both cells renew outer segment membranes at the same proportional rate, rod opsin mRNA would be 90-fold more abundant than cone opsin mRNA. For fish, the same reasoning suggests a 20-fold excess of rod over cone opsin mRNA. To test this directly, we hybridized blots to an antisense RNA probe synthesized from either the red or blue human cone opsin cDNA[13]. Under the stringency conditions at which FH97 revealed a single band, neither cone probe yielded any detectable signal, although several bands, including that marked by FH97, were labelled at lower stringencies (data not shown). This failure to detect any bands at high stringency suggests that the amount of cone mRNA present in our standard retinal RNA blots is below our ability to be detect it, as the numerical arguments above suggest.

Rod opsin mRNA abundance during a diurnal cycle was measured in the retinas of animals maintained in 12-hour light–dark cycles and killed every three hours starting half an hour after light onset. In both toads and fish, the mRNA level during the light phase of the cycle was nearly constant and decreased promptly fourfold to tenfold at night (Fig. 2).

Diurnal variation of rod opsin mRNA level could be a response to the light periodicity, or reflect endogenous, circadian signals. Such rhythms are recognized when the time-locked phenomenon occurs periodically in the absence of overt light–dark cycles. We measured opsin mRNA in toads that, after a 12 h : 12 h light : dark cycle, were then kept in darkness and killed at three-hour intervals beginning half an hour after the onset of subjective daytime (Fig. 3*a*) or half an hour after the beginning of the second subjective day (Fig. 3*b*). The rod opsin mRNA levels in these animals were nearly identical to those of animals

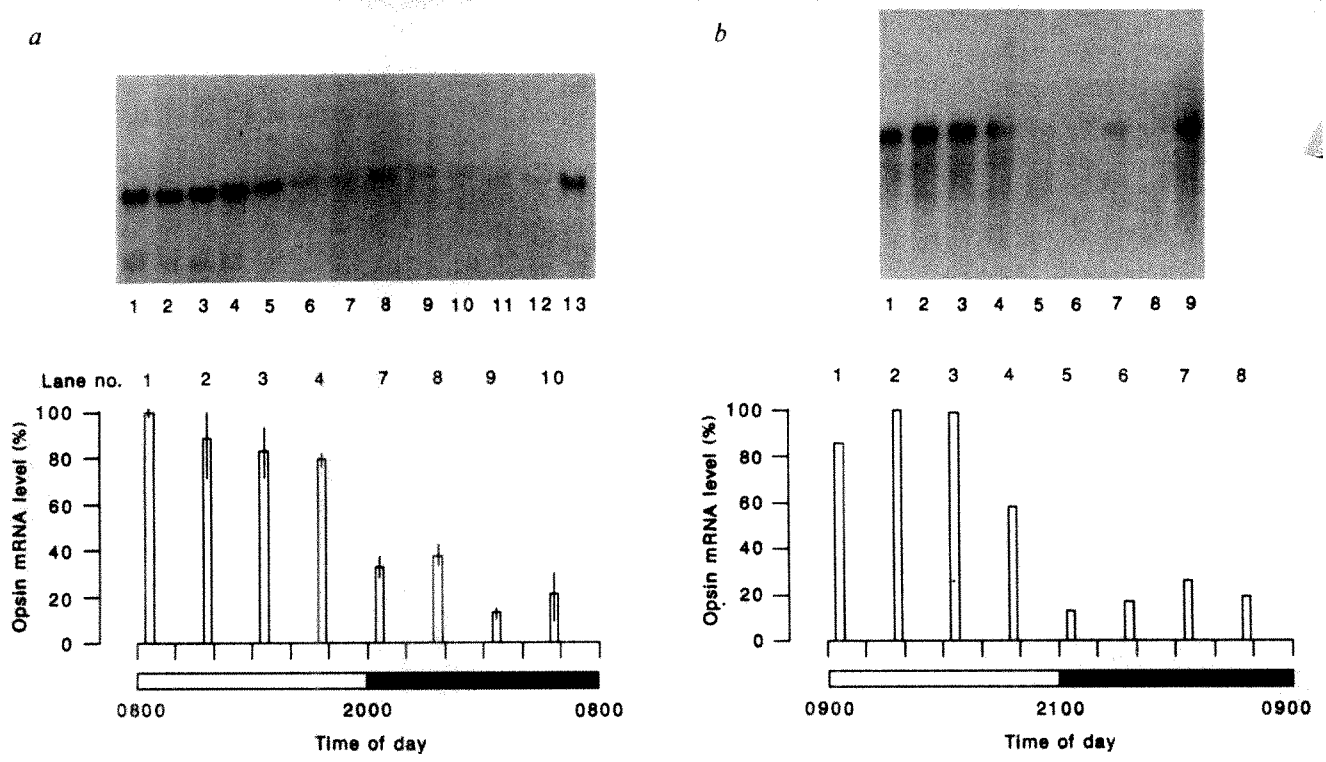

Fig. 2 Diurnal rhythm in the levels of retinal opsin mRNA in toad (*a*) and fish (*b*). The blot lanes contained total RNA pooled from two (toad) or six (fish) retinas of animals killed at intervals of three hours throughout a 12 h : 12 h light : dark diurnal cycle, beginning 0.5 h after lights on. In the autoradiogram of toad RNA (*a*) the identity and loading of each lane were: lane 1, 8:30 a,m,, 10 μg; lane 2, 11:30 a.m., 10 μg; lane 3, 2:30 p.m., 10 μg; lane 4, 5:30 p.m., 10 μg; lane 5, 5:30 p.m., 5 μg; lane 6, 5:30 p.m., 2.5 μg; lane 7, 8:30 p.m., 10 μg; lane 8, 11;30 p.m., 10 μg; lane 9, 11:30 p.m., 5 μg; lane 10, 11:30 p.m., 2.5 μg; lane 11, 2:30 a.m., 10 μg; lane 12, 5:30 a.m., 10 μg; lane 13, 8:30 a.m., 10 μg; sampled the following day. In the fish RNA blot (*b*) all the lanes were loaded with 10 μg: lane 1 at 9.30 a.m., with lanes 2–9 loaded with *samples collected* at three hourly intervals after that, so that lane 9 was loaded *with a sample collected* at 9.30 a.m. the following day. Densitometric analysis of the data and those of repeat experiments, is shown under the autoradiograms. The correspondence between RNA blot lanes and the histogram bars is shown by matching numbers. The density of each lane is expressed as a percentage of the greatest density measured in that autoradiogram. Bar height represents the average of 2–4 experiments and lines indicate the range of values measured. Comparison of RNA samples loaded in various amounts showed a typical error in loading of less than 10% (lanes 4–6).

Methods. All experiments were conducted in the winter, an important point as circadian rhythms and their entrainment can vary seasonally. Animals were adapted to a 12 h : 12 h light : dark cycle for at least six weeks. *Haplochromis* were bred from wild-caught stock and maintained at 28 °C. *Bufo* were obtained from commercial sources and maintainead at 25 °C in a constant temperature room. Illuminating light was spectrally matched to sunlight and its intensity was 3.1 W m^{-2} in the *Bufo* cage and 1.7 W m^{-2} at the water surface for *Haplochromis*. Autoradiograms were analysed with a laser densitometer (Ultrascan XL, LKB222-010, Bromma, Sweden).

that had experienced normal light cycles. Identical results were obtained for fish.

To investigate whether the increase in opsin mRNA during the daytime was synchronized with the light onset we measured the retinal mRNA level in toads killed at 2.5, 1.5 and 0.5 h before, and 0.5 h after light onset. At 2.5 h before lights-on, the opsin mRNA level was low, but it began to increase by 1.5 h before lights-on and was fully elevated 0.5 h before lights-on. Therefore the rise in opsin mRNA level is not activated by light onset but precedes it, suggesting that the levels of opsin mRNA are regulated by an endogenous clock.

We explored the relationship between light and the production of opsin mRNA by exposing toads and fish, entrained to a 12 : 12 in light : dark cycle, to 0.5 h of light at two different times during their normal dark period: 8 or 3 h before lights-on. In every case, the amount of opsin mRNA in animals exposed to light rose to day time levels (Fig. 3*d*). Thus, the mRNA level, although controlled by an endogenous rhythm can also respond directly to light.

We are now investigating whether the regulation we have observed in opsin mRNA is shared by other proteins in the rod. In higher vertebrates, diurnal variation in the levels of transducin mRNA[14,15] and opsin mRNA[15] has been observed, but whether these changes occur with an endogenous rhythm remains unexplored. Consistent with the rhythm of opsin mRNA level w describe, the amount of newly synthesized opsin in the frog ro inner segments can change by as much as 13-fold[16]. Becaus similar differences in amount were not observed in the oute segments[16], the variation in the amount of new opsin in th inner segments was presumed to reflect regulation of the siz of pools of opsin available for membrane synthesis. Our result suggest however, that changes in opsin content also reflec variation in the levels of its synthesis. Indeed, shortly afte light-onset there is fourfold increase in the amount of accumu lated opsin in the inner segment which declines only two hour after lights-off[17].

Although the kinetics of each step in outer segment renewa are not known for a single amphibian species, Fig. 4 is composite representation of the time course of events underlyin outer segment renewal from data obtained in *Rana*, *Xenopu* and *Bufo*. Disk membrane assembly[18] is delayed relative to th accumulation of rod opsin in the inner segment[17]. Opsi accumulation, in turn, lags behind the initial rise in cytoplasmi mRNA, which precedes light onset.

The selective advantages of diurnal variation in opsin mRN synthesis and disk membrane assembly are unknown. We specu late that the cone and rod renewal processes are out of phas with one another, rod opsin synthesis occurring mainly durin

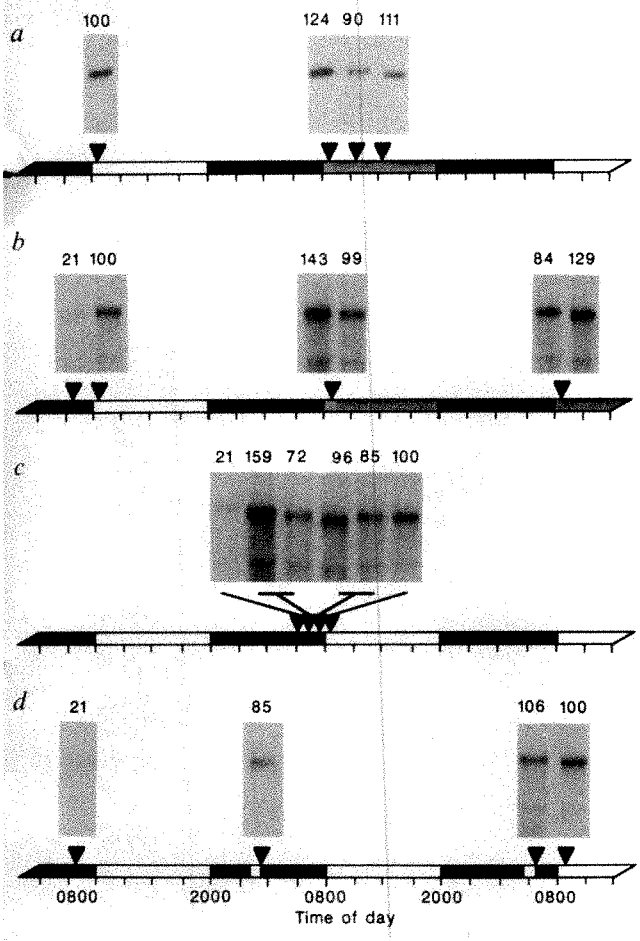

Fig. 3 Opsin mRNA levels are controlled by a circadian oscillator and are responsive to light. In each panel are autoradiograms from the same blot displayed to illustrate the experimental protocol. All lanes were loaded with 10 μg of toad retinal RNA. Band density relative to that measured 0.5 h after lights-on is expressed as a percentage and shown above each autoradiogram. *a*, The level of opsin mRNA rises in the absence of light during subjective daytime (indicated by the lightly shaded area). From the left, autoradiograms are from samples taken 0.5 h after lights on, and in darkness 0.5 h, 3.5 h and 6.5 h into subjective daytime. *b*, Opsin mRNA level is elevated at the time of subjective light onset after 24 or 48 h of continuous darkness. From the left, autoradiograms are from samples taken: in the dark, 2.5 h before lights turn on; in the light, 0.5 h after lights on; the next two in the dark, 0.5 h into the first subjective day; and the last two in the dark, 0.5 into the second subjective day. Samples from different animals are shown side by side to illustrate the range and reproducibility of the results. *c*, The increase in opsin mRNA level precedes light onset. From the left, sample identities are: in the dark, 2.5 h before light onset; the next two were in the dark, 1.5 h before light onset; the next two were in the dark, 0.5 h before light onset; the final one was in the light, 0.5 h after the light onset. *d*, Opsin mRNA levels rise in response to illumination during the night. Toads were exposed for 30 min to 2.9 W m^{-2} of continuous white light at two different times in the dark phase of their normal diurnal cycle. From the left, sample identities are: in the dark phase of the diurnal cycle (9 h of darkness) in the dark phase of the diurnal cycle (4 h of darkness) after 0.5 h illumination; in the dark phase of the diurnal cycle (9 h of darkness), after 0.5 h of illumination; in the light, 0.5 h after light onset.

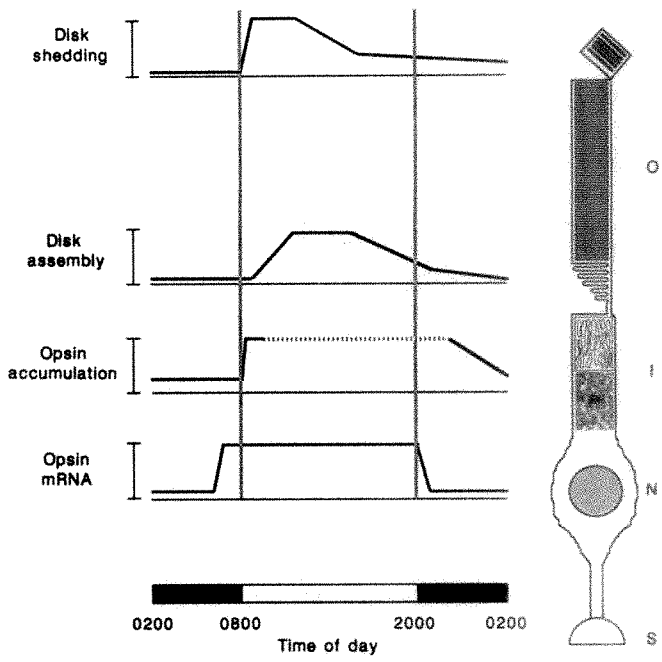

Fig. 4 Schematic illustration of the temporal and spatial relationships of events underlying rod disk assembly during a diurnal cycle based on data from three amphibia genuses maintained in a 12 h : 12 h light : dark cycle. A rod is sketched on the right with its major regions indicated: synapse (S), nuclear region (N), inner segment (I) and outer segment (O). The level of opsin mRNA in *Bufo* (compare with Fig. 2 and 3) increases one to two hours before light onset and remains high until shortly after dark onset. Opsin accumulation in the inner segment in *Rana*[17], begins at light onset and continues until two hours after dark onset. The rate of disk assembly in *Xenopus*[18] increases about one hour after light onset and decreases towards the end of the day. Disk shedding in *Xenopus*[18] and *Rana*[3] occurs once every four to five days when about 10% of the outer segment length is shed. Shedding begins at light onset and is completed within a few hours.

the day an cone opsin synthesis at night. If so, animals would have newly synthesized discs in place by dusk each day and rod photoreceptors would not be subject to structural changes at a time when vision is dominated by rod phototransduction.

We thank D. Ewing, L. Shelton, D. Palmerton and K. Van Dehy for technical help, H. Howard for photographic assistance, B. Gordon and Dr M. Grimes for advice and Drs Z. W. Hall, M. M. LaVail and R. M. Myers and A. V. Maricq for comments on this manuscript. Drs W. Baehr and M. Applebury provided the bovine opsin cDNA and Dr J. Nathans provided the human cone opsin cDNA. This work was supported in part by the NIH, the Medical Research Foundation of Oregon and REAC at USCF.

***Rimicaris exoculata*[1] is a shrimp that swarms over high-temperature (350 °C) sulphide chimneys at Mid-Atlantic Ridge hydrothermal fields (3,600 m)[1–7]. This shrimp lacks an externally differentiated eye[1], having instead a pair of large organs within the cephalothorax immediately beneath the dorsal surface of the transparent carapace, connected by large nerve tracts to the supraesophageal ganglion. These organs contain a visual pigment with an absorption spectrum characteristic of rhodopsin. Ultrastructural evidence for degraded rhabdomeral material suggests the presence of photoreceptors. No image-forming optics are associated with the organs. We interpret these organs as being eyes adapted for detection of low-level illumination and suggest that they evolved in response to a source of radiation associated with the environment of hydrothermal vents.**

Instead of tubeworms, clams and mussels that are characteristic of vent sites on the East Pacific Rise, the fauna of Atlantic vents is dominated by shrimp. Several species coexist, but *Rimicaris exoculata* is by far the most abundant. As indicated by its specific name, *R. exoculata* lacks eyestalks and corneas[1]. Instead, the shrimp possesses a pair of highly reflective patches on the dorsal surface of the cephalothorax. Dissection shows these patches correspond to an anteriorly fused, bilateral pair of specialized organs (Fig. 1), interpreted here as being novel

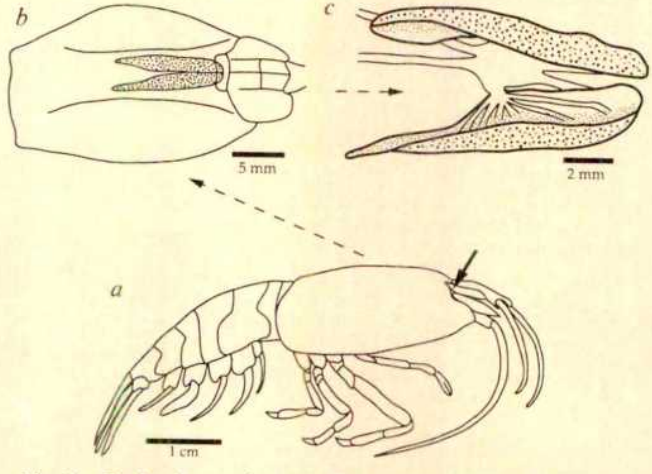

Fig. 1 *Rimicaris exoculata*. *a*, Lateral view. *R. exoculata* lacks eyestalks and conventional compound eyes. Solid arrow points to the location of eyes in the congeneric species *Rimicaris chacei*[1]. *b*, Oblique dorsal view showing the location of the novel visual organ (stippled area) underlying the thin transparent carapace. *c*, Dissection of the thoracic eye. The fused anterior tips have been separated along the midline to reveal the underlying connections to the supraesophageal ganglion.

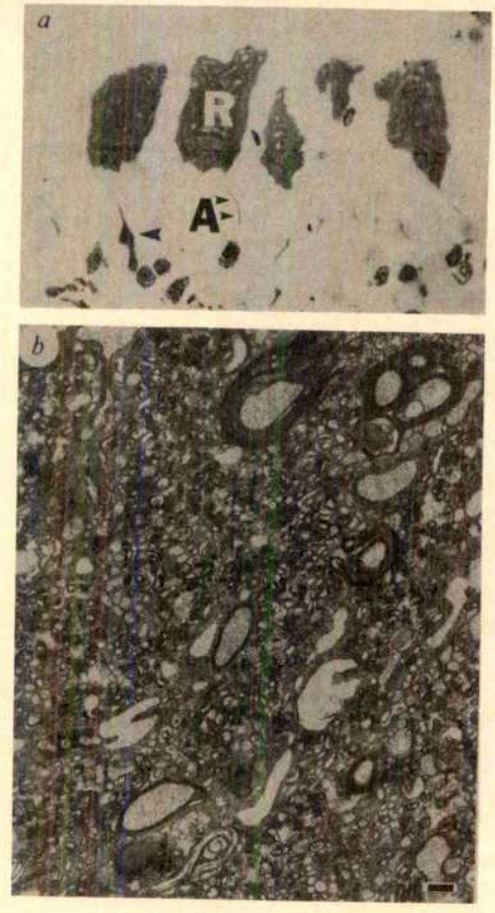

Fig. 2 Structure of photoreceptors of *Rimicaris exoculata*. *a*, Plastic 1-μm section stained with toluidine blue and cut normal to the eye surface. The rhabdomeral segment (R) is filled with a large elaboration of rhabdomere. The arhabdomeral segment (A) is severely attenuated (right arrowheads). The left arrowhead shows a photoreceptor nucleus. No other cellular elements are present. *b*, Electron micrograph of a region of rhabdomeral segment cytoplasm. The vesicles and whorls of membrane probably represent degraded microvilli from the rhabdom. The bar in *b* represents 13 μm in *a* and 0.5 μm in *b*.

eyes. The dorsal quarter of each eye is a compact zone of textur tissue which gives way ventrally to a fibrous web. Fibres of th web coalesce ventromedially into a nerve trunk that enters t fused supraesophageal ganglion in the same position as t optic nerve of other decapods[8]. Examination of 15-μm seri sections of paraffin-embedded tissue stained with haematoxyl and eosin reveals that each fan is composed of ommatidia-lil clusters of photoreceptors (5–7 cells per cluster; average, 6 There is no evidence for a lens or dioptric apparatus associate with each 'ommatidium'. Long axes of these 'ommatidia' a oriented perpendicularly to the carapace along the dorsal surfa of the organ. Each shrimp has about 9×10^3 receptor cells.

The distal portion of each photoreceptor is a cylindric rhabdomeral segment filled with microvillar membrane; th proximal portion is a highly attenuated arhabdomeral segme that contains the nucleus (Fig. 2*a*, left arrowhead). The ultr structure of the rhabdomeral segment (Fig. 2*b*) is almost ce tainly degraded from the living state[9–16] because the anima were fixed only after exposure to light at the ocean's surfac Nonetheless, the arrays of membranous vesicles and whorls ar suggestive of broken-down microvillar rhabdom as found i other invertebrate photoreceptors[12–16]. The reflective propert of the organ suggests a tapetal mechanism for increased ligh absorption by the receptors. As the reflective property is n

preserved in frozen or fixed specimens, we cannot determine the chemical nature of the tapetum, nor the extent to which it contributes to image-formation, if at all. Reflective cells[10-12] and extremely attenuated arhabdomeral segments[12] have been demonstrated in other crustaceans adapted to low ambient light levels. Thus, morphological evidence indicates that the unusual organs in *Rimicaris* are modified compound eyes, specialized for high sensitivity by extreme proliferation of rhabdomeral membrane, deletion of a dioptric apparatus, and presence of a tapetum.

Any organ specialized for photoreception should contain a rhodopsin-like protein. We performed rhodopsin assays on the available light-adapted specimens. Rhabdomeral membranes were partially purified by either isopycnic centrifugation on sucrose gradients[17] or differential centrifugation, and pigment was extracted from the membranes with digitonin. In the presence of hydroxylamine (NH_2OH), light bleaches a shrimp pigment that maximally absorbs at 500 nm and produces a product that maximally absorbs at 366 nm (Fig. 3). The difference spectrum closely resembles that of vertebrate rhodopsins. The location, relative magnitude and shape of the absorption bands indicate that the shrimp pigment is rhodopsin and that the product of the light-induced reaction is all-*trans*-retinaloxime. Formation of all-*trans*-retinaloxime, whose absorption peak is at 365-367 nm (ref. 17), indicates that before irradiation the chromophore is retinal, and is in a *cis*-isomer configuration[17]. Formation of retinaloxime also indicates that metarhodopsin is unstable to hydroxylamine under our experimental conditions. In this respect, pigment from *R. exoculata* resembles visual pigments of pelagic euphausiids[18].

Assuming the usual extinction coefficient for rhodopsin[17], 25 pmol pigment was extracted from each organ (50 pmol per shrimp) in the experiment shown in Fig. 3. This is a lower limit, because it ignores the fraction of pigment in the metarhodopsin state and because the limited amount of shrimp tissue prevented us from optimizing experimental conditions. Compared with crayfish[19] and horseshoe crabs[20], the eyes of *R. exoculata* contain at least 2-7 times more visual pigment.

Rhodopsin in *R. exoculata* absorbs maximally at a slightly longer wavelength than has been reported for other deep-sea-dwelling crustacea. For example, visual pigments of two species of pelagic euphasiids peak at 485-488 nm in digitonin extracts[18] and in mesopelagic decapods, λ_{max} varies from 485 to 495 nm by microspectrophotometry[21]. Some of these shrimps were also studied with electrophysiological techniques and showed maximal spectral sensitivity at about 500 nm (ref. 22).

Presence of a visual pigment supports morphological evidence that the thoracic organ is an eye; the unusual nature of this eye suggests it has a novel function. In the typical deep sea at depths of 3,600 m, bioluminescence is the only known source of ambient light. Macroorganisms produce flashes of relatively high-intensity light[23] with emission maxima clustered at around 460-490 nm[22]. In general, the λ_{max} of a visual pigment closely matches the spectral distribution of the ambient light. So it is tempting to relate the visual pigment, with its λ_{max} of 500 nm, to detection of bioluminescent phenomena by the shrimp. But then why should a new sensory organ evolve in place of a normal crustacean eye which is an adequate detector of visible light for most pelagic decapods?

The dominant physical features of the shrimps' environment are plumes of water at 350 °C. Detection of plumes could attract shrimp to feeding areas[7] and deter them from plunging into water hot enough to cook them. In a medium that does not transmit infrared radiation and in an environment of very steep thermal gradients (>100 °C per cm), detection of plumes with temperature-sensitive receptors is probably inadequate. Can *Rimicaris* 'see' plumes of hot water? Visual detection might be possible if the plumes emit light. Sources of light could be chemical (as in oxidation-reduction reactions or thermoluminescence) or physical (for example, Cherenkov radiation from radioisotopes or thermal black-body radiation). Of these possibilities, only thermal radiation from 350 °C water is a certain source of visible light.

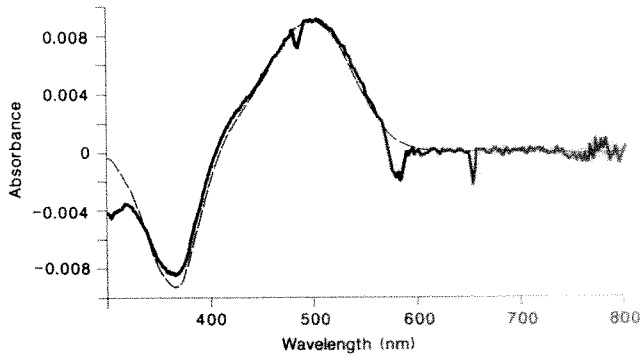

Fig. 3 Bleaching difference spectrum of visual pigment in *Rimicaris exoculata* (solid trace), obtained by subtraction of spectra measured before and after bleaching. Absorption due to reactants is positive and to products is negative. Bleaching destroys a shrimp pigment that maximally absorbs at 500 nm, typical of 'classical' rhodopsin, and creates a new pigment with a λ_{max} at 367 nm, which corresponds to retinaloxime. The same features are also seen in the difference spectrum of frog rhodopsin (dashed line) normalized to maximum absorbance at 500 nm. The slight mismatch in amplitudes of retinaloxime products may be attributed to a slightly greater (1.08 times) extinction coefficient for shrimp rhodopsin. Spikes at 660, 580 and 490 nm are instrumentation artefacts that regularly appear at these wavelengths.

Methods. All experiments were performed under dim red light with light-adapted animals. Organs of six thawed shrimps were dissected and homogenized in a solution of artificial cytoplasmic medium (80 mM NaCl, 335 mM Kisethionate, 200 mM sucrose, 4 mM $MgCl_2$, 10 mM EGTA, 10 mM HEPES titrated to *p*H 7.4 with NaOH)[26] including protease inhibitors (0.5 mM PMSF, 7 μg ml^{-1} of pepstatin, 50 μg ml^{-1} of leupeptin). The homogenized suspension was centrifuged for 30 min at 10,000*g*. The resulting pellet was resuspended in a hypotonic medium (10-fold dilution of the artificial cytoplasmic medium) and was centrifuged for 30 min at 51,000*g*. The final pellet was solubilized for 3 h at room temperature with 2% digitonin in amphibian saline solution (115 mM NaCl, 2.5 mM KCl, 1.5 mM $MgSO_4$, 10 mM HEPES titrated to *p*H 7.4 with 4 mM NaOH). Unsolubilized material was removed by centrifugation (2 min at 13,000*g*). The clear supernatant was used for subsequent analysis on a diode-array spectrophotometer (HP 8452, Hewlett-Packard). After the initial spectrum was recorded, 45 mM NH_2OH was added to the solution in the cuvette to destroy any retinochrome[27] present. Subsequently, the cuvette contents were exposed for 5 min to a light source that bleached ~95% of the rhodopsin. For about a 10-min interval both before and after bleaching, the time course of any dark reaction was monitored because the initial tissue homogenate contained relatively large concentrations of water-soluble pigments which could interfere with spectral analysis. In this experiment, the contribution of the dark-reaction was negligible and so no correction was made to the recorded bleaching difference spectrum. We obtained the same bleaching difference spectrum with rhabdoms that were purified by sucrose flotation[17]. We specifically searched the rhodopsin extract for the presence of membrane pigments that absorb in the red end of the visible spectrum. Our spectral analysis extended to 900 nm, but no pigment was detected that was preferentially sensitive to the longer wavelengths. The entire protocol from homogenization to extraction was also performed on control tissue derived from the abdomen of the shrimp, where no rhodopsin was detected.

Photons within the visible spectrum represent a very small fraction of the total photon flux emitted by a black body at 350 °C. But they may be sufficient to exceed the presumed threshold in shrimp[24]. If so, effective photon absorption by *R. exoculata* would be maximal at about 600 nm, given the spectral sensitivity of its rhodopsin. As a test of visibility of hot objects

with a 500 nm pigment, we demonstrated that dark-adapted humans can see a laboratory hot plate heated to 375 °C. *In situ* measurements of ambient light levels and the spectral characteristics and attenuation at hydrothermal vents are only just beginning[25].

We have demonstrated that the vent shrimp, *Rimicaris exoculata*, previously thought to be eyeless, has a thoracic eye that is well adapted for detection of very dim light. Thermal radiation from high-temperature plumes at black smoker chimneys could provide the light sensed by the shrimp. The role of the thoracic eye as a visual organ, however, will remain unresolved until more is known about its physiology and its unusual photic environment.

We thank S. Trapp, B. G. Calman, W. P. Dossert, C. K. Kier and T. D. Ryan for technical assistance, D. Pelli for discussion of threshold requirements for vision in shrimp, P. Rona and S. Humphris for providing us with shrimp, and F. Grassle and R. Hessler for advice and encouragement. This research was supported in part by an Ocean Ventures Award and a NSF Graduate Fellowship (C.L.V.D.) and by US Public Health Service (E.Z.S. and S.C.C.).

The visibility of 350 °C black-body radiation by the shrimp *Rimicaris exoculata* and man

Denis G. Pelli* & Steven C. Chamberlain*†

* Institute for Sensory Research, Syracuse University, Syracuse, New York 13244-5290, USA
† Department of Bioengineering, Syracuse University, Syracuse, New York 13244-1240, USA

The eye of the 'eyeless' shrimp *Rimicaris exoculata* is unusual in having no image-forming optics and a high concentration of rhodopsin[1]. The shrimps swarm around 350 °C hydrothermal 'black smoker' vents in the Mid-Atlantic Ridge[2]. There is no other known source of visible light in the shrimp's environment. The spectral sensitivity of rhodopsin is well matched to typical spectra of bioluminescence of organisms found at lesser depths, but other animals detect such emissions without the unusual features of the *R. exoculata* eye[1]. These two features are most easily understood as an adaptation for the detection of extremely faint sources o light. Physical calculations presented here indicate that the shrim could see the black-body radiation of the 350 °C vents, even thoug these sources are practically invisible to the human eye. This woul be useful to the shrimp as it feeds on sulphide-loving bacteria ver near to the vents[3] but must avoid the lethal 350 °C vents themselve

In the absence of behavioural evidence, no calculation ca prove that the shrimp sees anything. Therefore we take th opposite approach, assuming reasonable values for the fe unknown parameters, to show that the known physical con straints do not preclude rhodopsin-mediated detection of 350 °C black-body radiation by *R. exoculata*. We begin with the spectra of black-body emission and rhodopsin photosensitivity, and th amount of rhodopsin (50 pmol) in each shrimp eye[1]. We assum only that the black smoker is a black-body radiator, that ther is no intervening absorption over visible wavelengths by th deep sea water or the carapace of the eye, that a reflective laye at the back of the eye (which is apparent in photographs of liv shrimp[1]) reflects all light incident upon it, that the dark ligh (spontaneous isomerizations) in the shrimp eye is comparabl to that in other rhodopsin-based eyes, and that the shrimp' nervous system allows it to count (integrate) isomerizations from the entire eye.

A related question is whether this radiation would be visibl to man. Partially dark-adapted operators of the Alvin submarine parked next to the vent, were unable to see anything without artificial illumination (C. L. Van Dover, J. R. Delaney, L. M. Smith, J. R. Cann and D. B. Foster, manuscript in preparation and ref. 4). They did manage, however, to image the hydrothermal vent itself by a long-exposure photograph on a CCD (charge-coupled device) camera.

The spectral photon radiance of blackbody radiation is:

$$N_{e\lambda}(T,\lambda) = 2c\lambda^{-4}(e^{hc/kT\lambda} - 1)^{-1}\ \mathrm{sr}^{-1}, \qquad (1)$$

where T is temperature, λ wavelength, h Planck's constant, c the speed of light, k Boltzmann's constant, and sr is a steradian[5]. The dashed curve in Fig. 1*a* shows this spectrum for a 350 °C black body, relative to its maximum at wavelength 5,889 nm (wavenumber 0.17 μm^{-1}), well outside what is usually considered the visible range. The relative quantum efficiency $\alpha(\lambda)$ of rhodopsin is shown as a dotted curve, peaking at 500 nm (wavenumber 2 μm^{-1})[6]. Absorption is proportional to the product of radiation and quantum efficiency, and is shown as the dotted-and-dashed curve in Fig. 1*a*, relative to its maximum at 588 nm. Note that although the radiation and efficiency curves have very different peaks, at opposite ends of Fig. 1*a*, their tails overlap and have nearly complementary slopes, resulting in a nontrivial absorption peaking at an intermediate wavelength within the 'visible' range. We have not taken into account the transmission of the intervening water or optics—the carapace over the eye—because we do not have good *in situ* measurements over the relevant wavelengths. Distilled water is, however, transparent over the relevant range (200–1,500 nm) and the transmission outside this range has a negligible effect on the calculated total absorption at 350 °C.

Taking into account the radiation and efficiency, the equivalent number of 500 nm photons $s^{-1}\ m^{-2}\ sr^{-1}$ is:

$$N_e(T) = \int_0^\infty \alpha(\lambda) N_{e\lambda}(T,\lambda)\, d\lambda \qquad (2)$$

Assuming the eye is directed toward the 350 °C vent, that the vent is a sphere whose radius subtends an angle ω at the eye, and that the light makes two passes through the rhodopsin (before and after reflection at the back of the eye), the number of photons absorbed is:

$$N_a(T) = 2.9 \times 10^{-6}\ \mathrm{m^2\ sr}\ \sin^2(\omega) N_e(T) \qquad (3)$$

This is plotted in Fig. 1*b* as a function of temperature, assuming that the vent is sufficiently close to fill the shrimp's visual field,

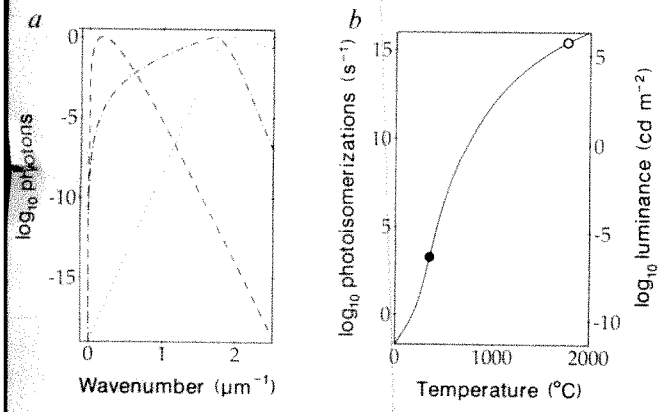

Fig. 1 *a*, The dashed line is the spectral photon radiance $N_{e\lambda}(T, \lambda)$ of 350 °C black-body radiation as a function of wavenumber, $1/\lambda$. The dotted line is the quantum efficiency $\alpha(\lambda)$ of rhodopsin. The dotted-and-dashed line is the product $N_{e\lambda}(T, \lambda)\alpha(\lambda)$. All three plots are relative to their maximum values. *b*, The number of photoisomerizations per second $N_a(T)$ in the shrimp eye (left-hand scale, assuming $\omega = \pi/2$) and the luminance $L'(T)$ (right-hand scale) as a function of the temperature of the black-body radiator. At 350 °C (●) the shrimp eye absorbs 1,800 photons per second under optimal conditions and the luminance is 0.43×10^{-6} cd m^{-2}. The open symbol (○) is explained below.

Methods. Taking into account the angular subtense ω of the target and the area A of the eye, the 500-nm-equivalent photon flux incident on the eye is $N(T) = \pi \sin^2(\omega)\,\mathrm{sr} \times A N_e(T)$. The total number of photons that are absorbed and isomerize rhodopsin in two passes (before and after reflection by the reflective layer) will be $N_a(T) = (1 - t_r^2)\,\gamma N(T)$, where γ is the quantum efficiency for isomerization and t_r is the transmission of the rhodopsin, which is given by $t_r = 10^{-\varepsilon C d}$, where ε is the molar absorbance at 500 nm, C is the concentration, and d is the path length. As the transmission is nearly 1, we neglect self-screening and make the approximation $(1 - t_r^2)\gamma = (1 - 10^{-2\varepsilon C d})\gamma \approx 2\ln(10)\varepsilon C d\gamma$. The product $\varepsilon\gamma$ is called photosensitivity and is approximately 4.06×10^4 l cm^{-1} mol^{-1} at 500 nm for rhodopsin *in vivo*[9]. Thus $N_a(T) = (2\ln(10)\varepsilon\gamma C d)\,N(T)$, which yields equation 3. The area A and thickness d of the rhodopsin layer in the eye cancel out; all that matters is the total amount of rhodopsin. We estimated the efficiency $\alpha(\lambda)$ of the rhodopsin by a Dartnall nomogram peaking at 500 nm, using Dartnall's long-wavelength extrapolation of that nomogram[6], that is, an asymptotic gradient $\Delta\log[\alpha(\lambda)]/\Delta(1/\lambda)$ of 1.05×10^{-3} cm. As a check, note that at 2,042K = 1768.85 °C (the open symbol, ○) the luminance is approximately 60,000 cd m^{-2}, in agreement with the 1967 definition of the candela[5]. The scotopic quantum efficiency of a standard human observer $W'_\lambda(\lambda)$ is approximately equal to the 500-nm rhodopsin quantum efficiency curve $\alpha(\lambda)$, except at short wavelengths (<500 nm), where lens absorption reduces efficiency, and at very long wavelengths (>780 nm) where $W'_\lambda(\lambda)$ is zero[5]. Substituting the standard scotopic relative quantum efficiency function $W'_\lambda(\lambda)$ for $\alpha(\lambda)$ in the definition of $N_{e\lambda}(T, \lambda)$ would have a negligible effect on the computed luminance at temperatures in the range 500 to 2,000 °C, but would have an ever-increasing effect at temperatures below 500 °C. At 350 °C the scotopic luminance is 0.43 10^{-6} cd m^{-2} assuming $\alpha(\lambda)$ but would be only 0.16×10^{-6} cd m^{-2} if we were to assume $W'_\lambda(\lambda)$ instead.

that is $\omega = \pi/2$. At 350 °C the photoisomerization rate is 1,800 s^{-1} (● in Fig. 1*b*).

We assume that isomerizations caused by photon absorption are indistinguishable from thermal isomerizations. Using the Baylor estimate[7] of the rate of thermal isomerization of rhodopsin (in monkey rods), 50 pmol of rhodopsin present in the shrimp eye will yield approximately 1,600 thermal isomerizations per second. To detect the 350 °C vent, the shrimp would have to discriminate a signal-plus-noise isomerization rate of 1,800 + 1,600 = 3,400 s^{-1} from a noise-alone rate of 1,600 s^{-1}. A brief integration time of only 20 ms would yield a decision variable with a signal-to-noise ratio of 6.4 (the mean signal divided by the standard deviation of the noise). This would allow the shrimp to detect correctly the lethal hot water 99.9% of the time, and to mistake ambient for hot water only 2% of the time. The photon flux and signal-to-noise ratio will, however, fall quickly if the shrimp is farther from the vent. Assuming a long integration time of 1 s, then for the shrimp to obtain a minimum useful signal-to-noise ratio of 1 (correctly detect hot water 50% of the time and mistake ambient for hot 16% of the time) the 350 °C vent must subtend at least $2\omega = 2.5°$. Thus a 10 cm wide vent could be detected from as far away as 2.3 m.

To assess the visibility of the vent by man we estimate its scotopic luminance:

$$L'(T) = \frac{1{,}700\ \mathrm{lm}}{\mathrm{W}} \frac{hc}{507\ \mathrm{nm}} \frac{N_e(T)}{\alpha(507\ \mathrm{nm})} \qquad (4)$$

where lm is a lumen. This is plotted in Fig. 1*b* over the temperature range 0 to 2,000 °C, using the right-hand vertical scale. At 350 °C (●) the luminance is 0.43×10^{-6} cd m^{-2}, which is slightly below the average threshold of 0.75×10^{-6} cd m^{-2} found by Pirenne[8] for seeing a large long-duration uniform disk by fully dark-adapted observers with natural pupils and unrestricted eye movements. Thus the operators of the Alvin submarine failed to see the vents by naked eye[4] because the vents were just below the threshold of visibility.

The process of segmentation, in which repeated homologous structures are generated along the anterior–posterior axis of the embryo is a widespread mechanism in animal development. In vertebrates, segmentation is most apparent in the somites and the peripheral nervous system[1,2], but the existence of repetitive bulges, termed neuromeres, in the early neural epithelium of vertebrates suggests that the CNS may also be segmented[3–9]. Consistent with this, cranial ganglia[8] and certain neurons[8,10] are associated with specific hindbrain neuromeres. Here, we report that *Krox*-20, a zinc-finger gene, is expressed in two alternate neuromeres in the mouse early hindbrain. This pattern subsequently decays and *Krox*-20 is transiently expressed in specific hindbrain nuclei. In addition, *Krox*-20 is expressed in early neural crest cells, and then in the neural crest-derived boundary caps, glial components of the cranial and spinal ganglia. The demonstration that neuromeres are domains of gene expression provides molecular evidence for the segmentation of the CNS.

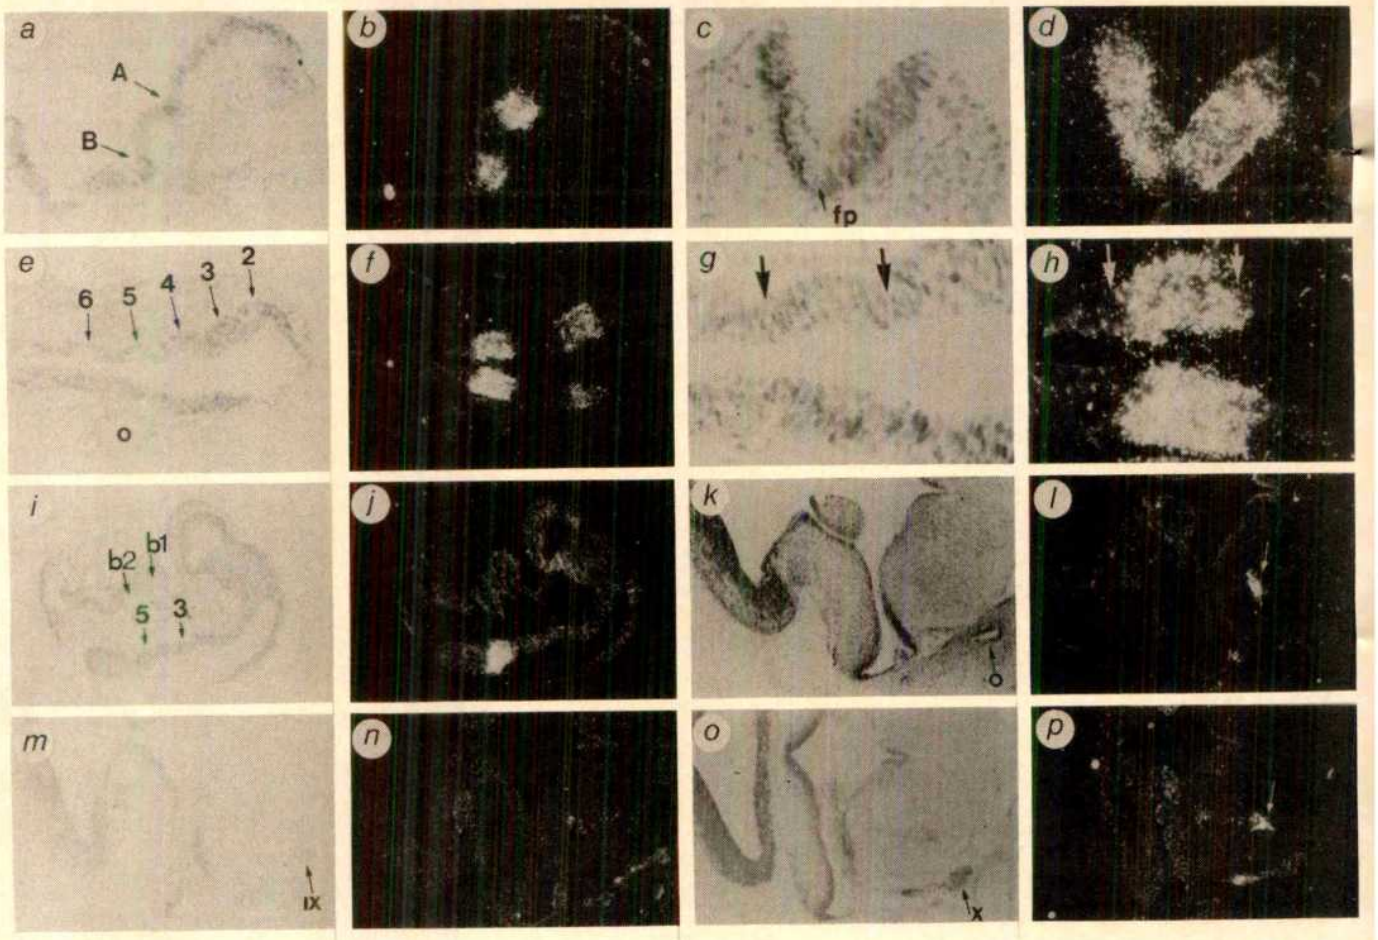

Fig. 1 *In situ* hybridization of ^{35}S-labelled antisense RNA probes for *Krox*-20 to sections of mouse embryos. *a*, *b*, Longitudinal section of 8.5-day-old embryo. *c*, *d*, Transverse section through proneuromere B of 8.5-day-old embryo. *e*, *f*, Coronal section through hindbrain of 9.5-day-old embryo. *g*, *h*, Higher magnification view of neuromere 5 in *e*, *f*; arrows indicate neuromere boundaries. *i*, *j*, Parasagittal longitudinal section of 10-day-old embryo. *k*–*p*, transverse sections through increasing caudal regions of the floor of the hindbrain of a 14.5-day-old embryo. *a*, *c*, *e*, *g*, *i*, *k*, *m* and *o* are brightfield photographs; *b*, *d*, *f*, *h*, *j*, *l*, *n* and *p* are the corresponding darkfield photographs. Embryos are staged according to the developmental ages described by Theiler[31]. Proneuromeres are designated A and B, and neuromeres are numbered 2, 3, 4, 5, 6 (see text for details). fp, floor plate; o, otocyst; b1, 1st branchial arch; b2, 2nd branchial arch; IX, glossopharyngeal ganglion; X, vagal ganglion.

Methods. *In situ* hybridization was performed as described[32]. The probe corresponded to *Krox*-20 3′ untranslated sequences (residues 2,417–2,834 of the cDNA, see ref. 11). Identical expression patterns were observed using a 5′ probe (residues 523–883 of the cDNA), although this gave a higher non-specific background (data not shown). No signals above background were observed in sense-strand control hybridizations (data not shown).

Krox-20 was originally identified as a serum-responsive gene in mouse NIH 3T3 fibroblasts, where its transcription is rapidly and transiently activated by the addition of serum or purified growth factors to quiescent cells[11,12]. *Krox*-20 encodes a protein with three zinc fingers similar to those of the transcription factor Sp1[11]. It therefore seems likely that *Krox*-20 encodes a transcription factor that has a role in early events in the resumption of growth in fibroblasts. A 3.2 kilobase (kb) *Krox*-20 transcript is detected in the thymus, spleen and testis of adult mice[11], and also in developing embryos (data not shown). We used *Krox*-20 probes for *in situ* hybridization analysis to examine the spatial and temporal pattern of expression of *Krox*-20 during mouse development.

Krox-20 transcripts were not detected in early gastrulation stage (7.5-day-old) mouse embryos (data not shown), but at 8.5 days they were found in two regions of the neuroepithelium of the prospective hindbrain (Fig. 1*a*, *b*). No other sites of *Krox*-20 expression were detected in serial longitudinal and transverse sections of the CNS. The regions of *Krox*-20 expression are in the vicinity of two invaginations of the neuroepithelium termed proneuromeres A and B[8]. Proneuromere B coincides with the centre of a site of *Krox*-20 expression, but proneuromere A does not, and analysis of serial sections revealed no simple spatial relationship between proneuromeres and sites of *Krox*-20 expression. At this stage, these sites of *Krox*-20 expression are 8–10 cells in length. In transverse sections through sites of expression, *Krox*-20 transcripts were detected throughout the neuroepithelium, except for the floor plate (Fig. 1*c*, *d*). By 9.5 days, seven neuromeres had formed in the hindbrain, and longitudinal (data not shown) and coronal sections (Fig. 1*e*, *f*) revealed that *Krox*-20 transcripts are restricted to two alternate neuromeres: neuromeres 3 and 5 of the hindbrain (neuromere 5 flanks the anterior end of the otocyst[8]). The boundaries of *Krox*-20 expression coincide with the sulci separating neuromeres (Fig. 1*g*, *h*). At 10 days of development, *Krox*-20 expression has been down-regulated in neuromere 3, but persists in neuromere 5 (Fig. 1*i*, *j*), and by 10.5 days expression is barely detectable in the hindbrain (data not shown). The down-regulation of expression in neuromere 3 before neuromere 5 may reflect the anterior–posterior direction

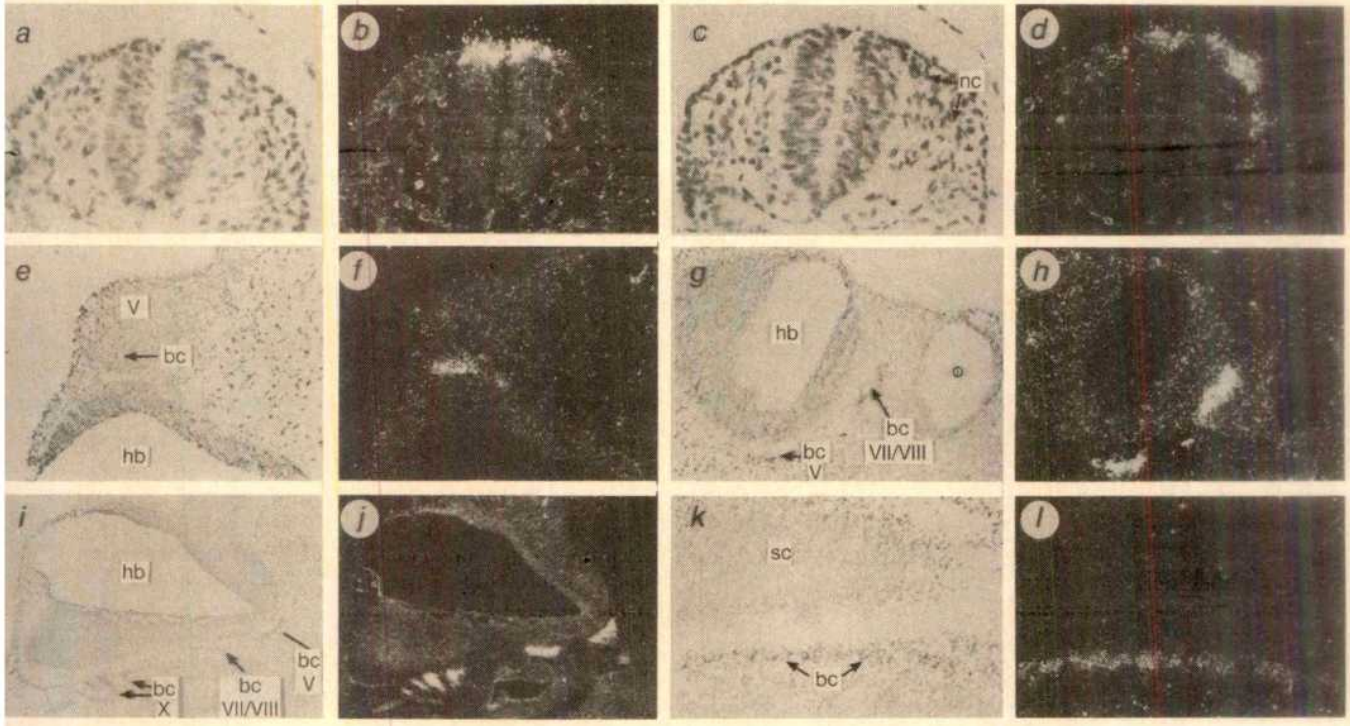

Fig. 2 Expression of *Krox*-20 in the developing peripheral nervous system. The pattern of *Krox*-20 expression was determined by *in situ* hybridization of radiolabelled probes to some embryo sections. *a, b*, Transverse section of 8.5-day-old embryo through region immediately caudal to proneuromere B (see Fig. 1*c, d*). *c, d*, Transverse section of 8.5-day-old embryo caudal to that shown in *a, b*. *e, f*, Transverse section through trigeminal ganglion of 10.5-day-old embryo. *g, h*, Parasagittal longitudinal section through hindbrain of 10.5-day-old embryo. *i, j*, Parasagittal longitudinal section through hindbrain of 12.5-day-old embryo. *k, l*, Longitudinal section through spinal cord of 14.5-day-old embryo. Arrows indicate sites of *Krox*-20 expression. Boundary caps (bc) of trigeminal (V), facial/vestibular (VII/VIII), vagal (X) and dorsal root ganglia are labelled. nc, Neural crest; hb, hindbrain; o, otocyst; sc, spinal cord. Methods were as in Fig. 1 legend.

of CNS maturation. *Krox*-20 expression was not detected in the CNS at 12.5 days of development, but at 14.5 days there was expression in two columns of cells in the hindbrain. Serial transverse sections reveal *Krox*-20 expression in a dorso-lateral group of cells (Fig. 1*k, l*) that extend from the level of the vestibular ganglion to the glossopharyngeal ganglion. Only low levels of *Krox*-20 transcripts are detected immediately caudal to the latter ganglion (Fig. 1*m, n*), but a more ventro-medial column (Fig. 1*o, p*) of *Krox*-20-expressing cells is detected from the level of the vagal ganglion to the caudal end of the hindbrain. The identity of these sites of expression is unclear because of the rapid changes in the formation and migration of hindbrain nuclei at this time. *Krox*-20 expression was not detected in the CNS of 16.5-day-old embros; this was not due to poor retention of RNA as other probes can detect similar levels of transcripts in the hindbrain of 14.5-day-old and 16.5-day-old embryos. Thus, *Krox*-20 seems to be transiently expressed in specific nuclei of the hindbrain.

Analysis of serial transverse sections through 8.5-day-old embryos revealed *Krox*-20 transcripts in neural crest cells as well. In regions immediately caudal to proneuromere B (see Fig. 1 *a–d*), *Krox*-20 transcripts are detected in the dorsal neural epithelium (Fig. 2*a, b*), where neural crest cells originate, and, in more caudal sections, early migratory neural crest cells express *Krox*-20 (Fig. 2*c, d*). At 10.5 days of development, *Krox*-20 expression was detected in boundary cap cells of the trigeminal and vestibular/facial ganglia (Fig. 2*e–h*). Boundary caps are comprised of neural crest-derived glial cells[13] that are located adjacent to the neuroepithelium at the sites of its penetration by sensory afferent and motor efferent axons[14]. By 12.5 days, *Krox*-20 expression was detected in the boundary caps of all the cranial ganglia (Fig. 2*i, j* and data not shown) and the sensory and motor roots of the dorsal root ganglia of the spinal cord (Fig. 2*k, l*, and data not shown). The detection of *Krox*-20 transcripts in certain early neural crest cells suggests that these precursors of the boundary cap cells, whose differentiation has been initiated during, or before, neural crest migration. Although much of the neural crest seems uncommitted in its fate at early stages of migration[15], there is evidence for early determination of some neural crest populations[16,17]. In view of the association of *Krox*-20 gene transcription with the G_0 to G_1 transition in fibroblasts[11,12], expression of this gene could be associated with the proliferation of boundary cap cells[14]. *Krox*-20 expression does not, however, correlate with cell division in the neuromeres, and later occurs in post-mitotic neurons.

Despite much debate about the possible developmental significance of neuromeres[3–9], there was no direct evidence for segmentation in the hindbrain of higher vertebrates. Our observation that certain neuromeres are domains of *Krox*-20 expression provides molecular evidence that neuromeres are segments. Localized *Krox*-20 expression precedes the formation of neuromeres, suggesting that segmentation may occur before it is manifested at the morphological level. The absence of a correlation between *Krox*-20 expression and proneuromeres is consistent with the lack of correspondence between these early-forming sulci and neuromeres in the rodent embryo[9]. Recent studies of neuronal development in the chick hindbrain have shown that it occurs in a segmental pattern in hindbrain neuromeres (rhombomeres) 2–6[18]. Motor neuron formation is first initiated in neuromeres 2, 4 and 6, and then in neuromeres 3 and 5, yielding an alternating pattern of cellular development. The alternating pattern of *Krox*-20 expression in the segmented region of the hindbrain is intriguing, in view of the similar expression pattern of pair-rule segmentation genes in the

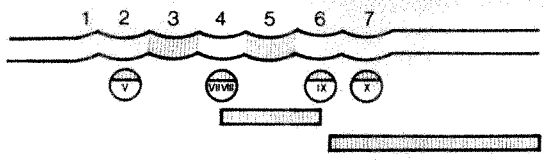

Fig. 3 Summary of sites of *Krox*-20 expression, showing the spatial relationship between the various sites of *Krox*-20 expression. In the upper part, the neuromeres (1-7) are shown; segmentation at the level of cellular development occurs within neuromeres 2-6 (ref. 18), and *Krox*-20 expression occurs in alternate neuromeres within this domain. Below are aligned representations of the cranial ganglia and boundary caps (V-X). Cranial ganglia caudal to the neuromeres are not indicated. The lower part of the figure shows the relative position of the nuclei that express *Krox*-20 at 14.5 days of development. The sites of *Krox*-20 expression are indicated by shading.

Drosophila melanogaster embryo[19,20]. It is possible, however, that *Krox*-20 expression may be associated with phenotypic characteristics unique to neuromeres 3 and 5. For example, motor neuron formation is delayed in these neuromeres, and they are the only definitive neuromeres not adjacent to cranial ganglia (Fig. 3). There is no obvious relationship between the transient expression of *Krox*-20 in neuromeres and, later on, in specific hindbrain nuclei; the rostral column of cells expressing *Krox*-20 overlaps with the hindbrain region derived from neuromere 5, but the more caudal nucleus has no such overlap (Fig. 3). Thus, it seems likely that *Krox*-20 acts in distinctive cell populations at different stages of hindbrain development. There are other examples of this behaviour for genes with early segment-restricted expression, as many segmentation and homoeotic genes in *Drosophila* are subsequently expressed in certain neurons in all segments[21].

Our data suggest that *Krox*-20, as a putative transcription factor, could be part of a regulatory network coupled to hindbrain segmentation. The expression of mouse homoeobox (*Hox*) genes in restricted anterior-posterior domains of the neural tube suggests that they may specify position along the body axis[22,23]. Many of these genes have anterior limits of expression in the hindbrain, although a possible relationship with neuromeres has been observed only for *Hox*-1.5[24]. It is therefore pertinent to investigate whether *Krox*-20 interacts with *Hox* genes or with other members of the mouse zinc-finger gene family[25-26]. One such gene, *mKr2*, is expressed throughout the developing CNS and peripheral nervous system[27], and the mouse genome contains at least one other zinc-finger gene closely related to *Krox*-20[28-30]. It will be interesting to determine whether other members of this group are expressed in the developing nervous system and, in particular, whether any have neuromere-restricted domains of expression.

We thank Andrew Lumsden and Roger Morris for valuable discussions and useful advice, and Robb Krumlauf for critical reading of the manuscript.

Transgenic mice overexpressing the mouse homoeobox-containing gene *Hox-1.4* exhibit abnormal gut development

Debra J. Wolgemuth*†, Richard R. Behringer‡, Margaret P. Mostoller†, Ralph L. Brinster‡ & Richard D. Palmiter§

The mouse homoeobox-containing genes exhibit temporally an spatially specific patterns of expression in embryonic and adul tissues and are thought to be important in regulation of develop ment and cellular differentiation, perhaps by mechanism analogous to homoeotic genes in *Drosophila melanogaster*[1-4] There has been no direct demonstration that expression of thes mammalian genes can affect developmental processes, howeve *Hox-1.4*, like other mouse homoeobox-containing genes, has bee shown to be expressed in specific regions of the mid-gestatio embryo[5-8], but is unique in that its highest level of expression i the adult animal is restricted to developing male germ cells[5,8,9] We have introduced a construct carrying the mouse *Hox-1.4* gen into the germ line of mice to begin to identify the *cis*-actin elements required for proper expression and to assess the con sequences of increasing *Hox-1.4* gene expression. The construc was designed to produce normal Hox-1.4 protein from transcript that are distinguishable from the products of the endogenous gene The integrated transgene seemed to exhibit the appropriate tissu specificity of expression, but transcript levels were elevated i certain tissues, particularly the embryonic gut. This overexpressio correlated with changes in the normal developmental program o the gut, resulting in an inherited abnormal phenotype known a megacolon.

Hox-1.4 is a member of a cluster of at least six homoeobox containing genes occupying about 100 kilobases (kb) of con tiguous DNA on mouse chromosome 6 (refs 8, 10, 11). Althoug the putative translation stop codon and other structural feature of the 3′ end of the *Hox-1.4* gene have been determined, the 5 end has not been characterized. We therefore generated a con struct (Fig. 1*a*) which contained ~10 kb of sequence upstrean of the homoeodomain and abuts the upstream *Hox-1.* gene[10,12,13].

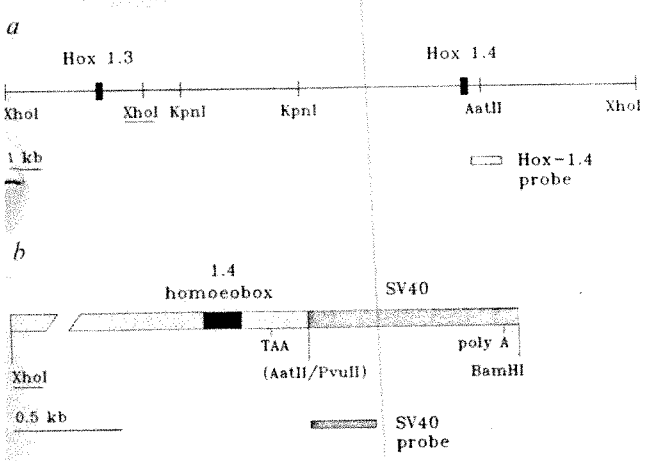

Fig. 1 Map of *Hox-1.4* and construct used to generate transgenic mice. *a*, Map of the *Hox-1.4* gene and flanking regions. Pertinent restriction sites are indicated. *b*, The *Xho*I–*Bam*HI fragment that was microinjected to generate transgenic mice.
Methods. A plasmid spanning *Hox-1.3* and *Hox-1.4* was cut at the unique *Aat*II site to remove the endogenous poly(A) site of *Hox-1.4* (ref. 20). A *Pvu*II–*Bam*HI fragment of SV40 (position 3,506 to 2,533) containing a polyadenylation signal[21] was ligated to the *Aat*II site, downstream of the translation stop codon of *Hox-1.4*(refs 9,20). The 'Hox-1.4 probe' in *a* was used to detect endogenous mRNA[5,20]. To detect transgenic mRNA only, the SV40 probe (Fig. 1*b*) was used. Both fragments were subcloned into pGEM vectors purchased from Promega.

We assumed that this DNA fragment contains the complete coding sequence of *Hox-1.4* and would be capable of producing functional Hox-1.4 protein if expressed. To distinguish the transcripts generated by this construct from those of the endogenous *Hox-1.4* gene, about 400 base pairs (bp) of 3′ untranslated region of *Hox-1.4* was substituted with simian virus 40 (SV40) T-antigen coding region and poly(A) addition site (Fig. 1*b*). Transgenic mRNAs should be ~400 nucleotides (nt) longer than endogenous *Hox-1.4* transcripts and easily distinguishable because of the SV40 sequences.

Initially, we characterized two transgenic lines (1974-3 and 1975-2), each carrying multiple copies of the 10 kb Hox-1.4-SV construct at a single integration site. Inheritance of the transgenes in the 1974-3 lineage is exclusively by males and is therefore genetically linked to the Y chromosome, whereas the pattern of inheritance in the 1975-2 lineage is autosomal.

The tissue specificity and level of expression of the *Hox-1.4* transgene in adult tissues from both lines was examined by northern blot hybridization analysis. SV40-containing mRNAs were readily detected in testes of the 1975-2 lineage, but not in the other adult tissues examined (Fig. 2*a*). Occasionally, a low level of SV40-containing mRNA was detected in lung from these transgenic mice, consistent with the low level of expression of the endogenous *Hox-1.4* gene observed in this tissue (R. Krumlauf, personal communication). Recent preliminary data on the pattern of expression of Hox-1.4-SV constructs with 5 kb (rather than 10 kb) of DNA 5′ to the *Hox-1.4* homoeobox reveal this same pattern of tissue distribution of transgenic mRNAs in the adult animals—highest levels in the testis and barely detectable levels in lung and kidney (another somatic tissue exhibiting low levels of endogenous *Hox-1.4* expression: R. Krumlauf, personal communication; C. M. Viviano and D. J. Wolgemuth, unpublished observations) (data not shown). These observations suggest that the *cis*-acting regulatory elements responsible for the appropriate tissue-specific expression of *Hox*-1.4 are present in these constructs. The levels of Hox-1.4-SV transgenic transcripts however, in the testes of adult males of the 1975-2 lineage (Fig. 2*b*), as well as in testes of two additional lines carrying the 10 kb

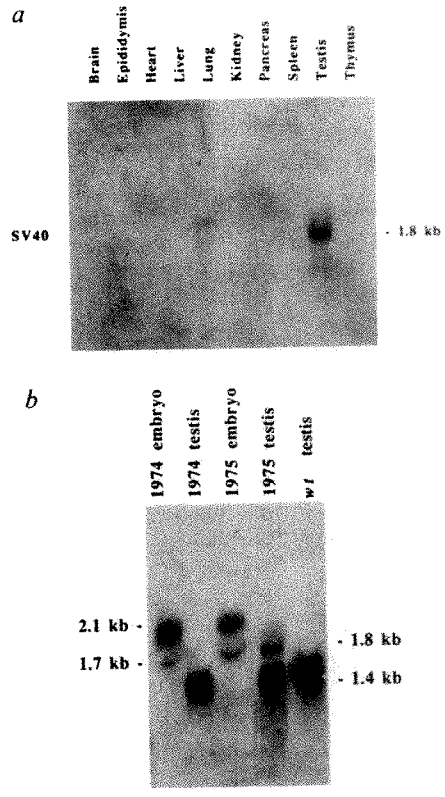

Fig. 2 Northern blot hybridization analysis of expression of the 10 kb Hox-1.4-SV transgene. *a*, Expression of the 10 kb Hox-1.4-SV transgene in adult tissues of the 1975-2 lineage. Total RNA (25 μg) from tissues of an adult (>45-day-old) male mouse from the 1975-2 lineage was examined for the presence of transgenic mRNA using the SV40 probe. Transgenic mRNAs of the predicted ~1.8 kb size were readily detected in testis but not reproducibly in other tissues. *b*, Expression of transgenic and endogenous *Hox-1.4* transcripts in mid-gestation embryos and adult testes of the 1975-2 and 1974-3 lineages. RNA was isolated from transgenic day-12.5 (day 0.5 is day of plug) whole embryos or from testes of adult animals. Total RNA (~25 μg) was loaded per lane. We used the *Hox-1.4* probe, which detects both transgenic and endogenous *Hox-1.4* transcripts (see Fig. 1). The larger transcripts were transgenic, as confirmed by hybridization with the SV40 probe (data not shown). Transcripts of 1.7 and 1.4 kb were produced from the endogenous gene in day-12.5 embryos and adult testes, respectively, as expected[5]. Transgenic mRNAs of ~2.1 and 1.8 were detected in embryo and testis RNA, respectively, from the 1975-2 lineage, whereas the 1974-3 lineage expressed the transgene only in embryos, not in testis.
Methods. Transgenic mice were generated by microinjection of the 10kb Hox-1.4-SV construct into the pronuclei of C57B1/6 × SJL F_2 fertilized eggs by standard prodecures[22]. Weanlings were identified as transgenic by dot hybridization of DNA collected from tails[22]. Embryos were identified by analysis of DNA from placenta and extra-embryonic membranes. Tissues were obtained from progeny of founder animals, unless otherwise stated. RNA was isolated by the LiCl precipitation method[23]. Poly(A)$^+$RNA was isolated as described[24]. Total or poly(A)$^+$ RNA was electrophoresed on 0.8% agarose/2.2 M formaldehyde gels[25], transferred to Genescreen Plus (New England Nuclear), cross-linked under UV light for 7 min, and hybridized at high stringency[25] as prevously described[26]. Isolated inserts were labelled by nick translation with ^{32}P[dXTP][27]. Final washes were at 0.1 × SSC, 68 °C. Filters were exposed to XAR film with intensifying screens.

Hox-1.4-SV transgene and two lines carrying the 5 kb Hox-1.4-SV transgene (data not shown), were lower than those produced by the endogenous gene. This suggests that elements involved in quantitative regulation of *Hox-1.4* mRNA levels may be missing.

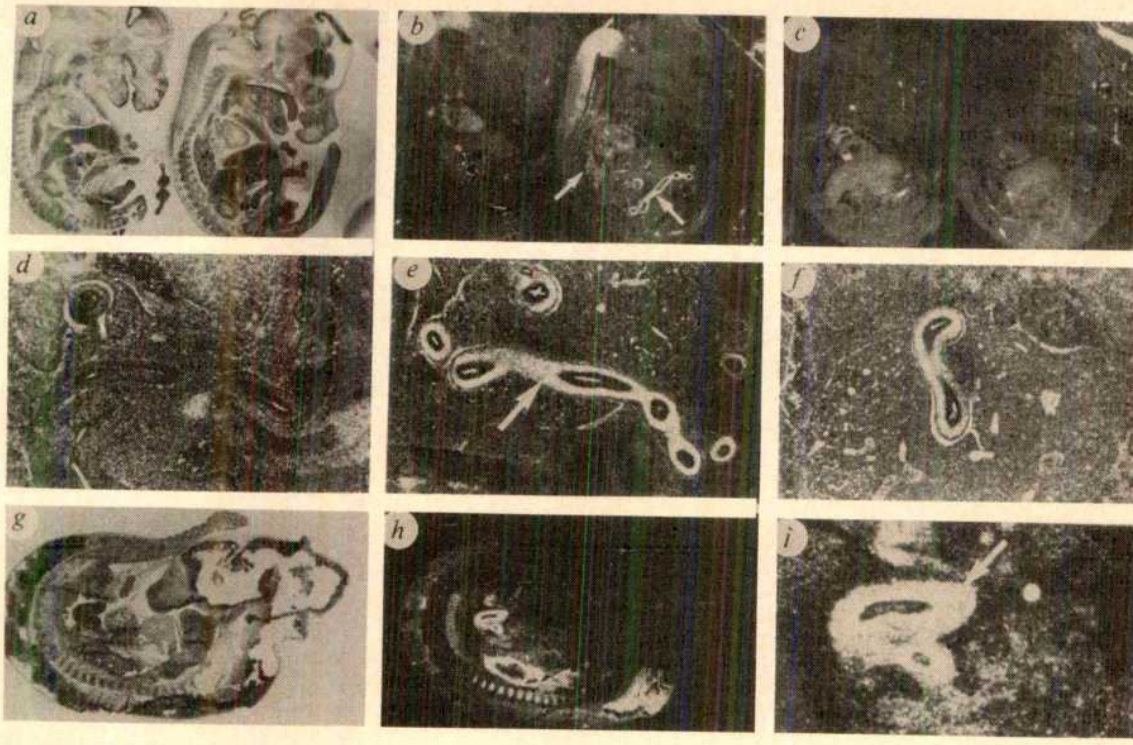

Fig. 3 *In situ* hybridization analyses of endogenous and transgenic *Hox-1.4* transcripts in mid-gestation embryos. *a*, *b*, Parasagittal sections through day 12.5 embryos of the 1974-3 lineage photographed with bright-field (*a*) or dark-field (*b*) optics. The embryo on the left is a non-transgenic litter-mate of the transgenic embryo on the right. The antisense *Hox-1.4* probe used detects both endogenous and transgenic *Hox-1.4* mRNAs. Localization is clearly seen in the more rostral region of the spinal cord and in the caudal myelencephalon of the wild-type and transgenic embryos. The labelling is more intense in the transgenic mouse, indicating higher levels of *Hox-1.4* mRNA. Elevated levels of expression are also evident in the lung and intestine of the transgenic embryo (arrows). The labelling over the heart is non-specific, as heart is also labelled using the sense (control) probe (*c*). The hybridization pattern of antisense *Hox-1.4* (*d*, *e*) or SV40 (*f*) RNA in regions of the developing gut of wild-type (*d*) and transgenic (*e*, *f*) embryos are shown at higher magnification in *d*, *e*, and *f*. Labelling is restricted to the mesenchymal layer of the developing gut (arrows). In the transgenic embryo, the SV40-containing transgenic mRNAs are readily detected and exhibit localization to the mesenchymal layer (*f*). Expression of transgenic *Hox-1.4* mRNA is also elevated in gut of mid-gestation (day 11.5) embryos of the 1975-2 lineage (*g*–*i*). *g*, A bright-field photograph of the embryo in *h*; *i*, an enlargement of portions of the gut. The labelling is again restricted to the mesenchymal layer (arrows in *i*).

Method. Procedures followed previous protocols[6,28], except where noted. Embryos were recovered at day 11.5 and 12.5 of gestation, fixed overnight at 4 °C in 4% paraformaldehyde: 0.1 M phosphate buffer, *p*H7.5, followed by equilibration in 30% sucrose in 0.1 M phosphate buffer, *p*H 7.5. Specimens were embedded in O.C.T. compound (Miles) and sectioned on a cryostat. Sections were collected onto poly-L-lysine coated slides. Hybridization conditions were as described[9,28], except that 10 mM dithiothreitol was included in the first post-hybridization wash. RNA probes were synthesized from the T7 or SP6 promoters in the GEM3 plasmid vector to generate antisense or sense RNA using ^{35}S[UTP]. Specimens in panels (*b*, *d*, *e*) were hybridized with antisense *Hox-1.4* probe panel (*c*) with sense *Hox-1.4* RNAs; panels (*f*, *h*, *i*) with antisense SV40 RNA probe.

There was no detectable expression of the transgene in testes (Fig. 2*b*) or other adult tissues tested (data not shown) of the Y-linked 1974-3 lineage. The lack of expression of the transgene in the Y-linked lineage may be due to the condensation during meiotic prophase of the X and Y chromosomes into the sex vesicle, which is purported to be transcriptionally inactive[14,15].

The northern blot analysis further revealed that in mid-gestation embryos of both the 1974-3 and 1975-2 lineages, the levels of transgenic mRNAs were at least fivefold higher than the levels of the endogenous *Hox-1.4* transcripts (Fig. 2*b*). To determine whether the elevated levels of the transgenic mRNAs in the embryos could be attributed to the presence of higher levels of transcripts in tissues normally expressing *Hox-1.4*, to expression of the transgenic *Hox-1.4* in ectopic sites, or to a combination of both, mid-gestation embryos of the 1974-3 and 1975-2 lineages were examined by *in situ* hybridization analysis.

The endogenous *Hox-1.4* gene is expressed at high levels in the developing nervous system of the mid-gestation mouse embryo, especially within the spinal cord, as shown by both northern blot[5] and *in situ* hybridization analysis[6,7]. Both the non-transgenic and transgenic 12.5-day-old embryos shown in Fig. 3*b* exhibit the expected abundant expression of *Hox-1.4* in portions of the spinal cord and myelencephalon (Fig. 3*a*, *b*). Hybridization signals were also observed in heart. As the signal detected in heart was also observed in experiments using sense *Hox-1.4* probes, however (Fig. 3*c*), it presumably represents non-specific, artefactual hybridization.

In the transgenic embryo, the spatial distribution of *Hox-1.4*-containing mRNAs in the myelencephalon and spinal cord was similar to controls, but the levels seemed elevated (Fig. 3*b*). *Hox-1.4*-containing mRNAs were more readily detected in the lung of the transgenic rather than non-transgenic embryo, suggesting that there are slightly elevated levels of expression in this tissue as well (Fig. 3*b*). We believe that the levels of *Hox-1.4* mRNA are elevated at least twofold in both the central nervous system and lung of the transgenic embryos because the grain density was consistently higher and the time required to obtain a signal was consistently shorter than with litter-mate controls using the *Hox-1.4* probe. In addition, these elevated levels are due to expression of the transgene as both tissues hybridized with the SV40 probe (Fig. 3*h* and data not shown).

Most striking of all was the intense labelling observed in the gut of transgenic embryos; little or no labelling above background was observed in the gut of non-transgenic embryos. This

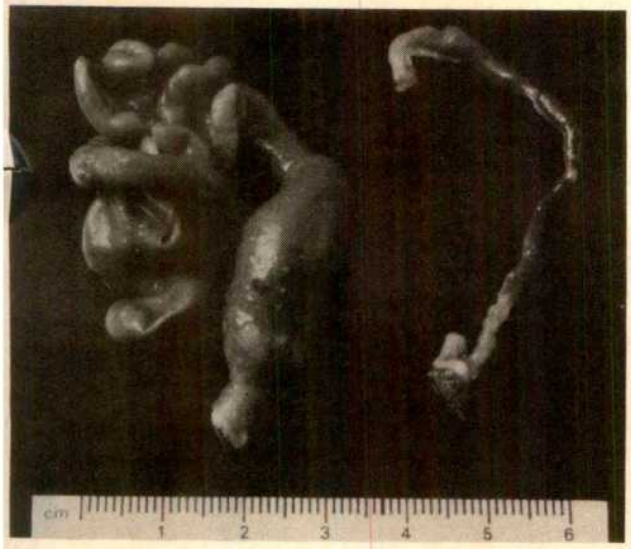

Fig. 4 Example of the megacolon phenotype from the 1975-2 lineage. Left, the dissected colon and a portion of the intestinal region of an adult mouse exhibiting profound megacolon. Right the colon of a normal adult mouse. The distention begins ~0.5 cm from the most distal region of the colon.

labelling was observed in both the 1974-3 (Fig. 3*b–e*) and 1975-2 (Fig. 3*h, i*) lineages. Hybridization with the SV40 probe confirmed that the transcripts observed in the gut were due to expression of the transgene (Fig. 3*f, h, i*). The transcripts were clearly localized to the region of mesenchyme in an evenly distributed, non-punctate pattern. No labelling above background was observed in the inner (mucosa) or outer (serosa) layers. Although it was not evident in the *in situ* hybridization experiments shown in Fig. 3, *Hox-1.4* mRNA has been detected by *in situ* analysis in the mesenchyme of the gut and lung of normal day-12.5 embryos (D. Duboule, S. Gaunt and R. Krumlauf, personal communication). Thus, the elevated expression of the *Hox-1.4* transgene probably represents overexpression of *Hox-1.4* in cells that normally express this gene, rather than ectopic expression.

The highly elevated levels of *Hox-1.4* in the developing gut of both the 1974-3 (Fig. 3*a–f*) and 1975-2 (Fig. 3 *g–i*) lineages are particular interesting because of the unexpected phenotype that develops in these mice. Our initial analysis concentrated on the 1974-3 lineage because the animals were relatively healthy and bred well. The 1975-2 lineage was quite difficult to establish. We determined that the founder male was a germ-line mosaic, transmitting the transgene to ~20% of the embryos. Only two of more than 100 weanlings generated from this founder animal carried the transgene, however. These observations suggested that transgenic pups were dying between birth and young adulthood; we have subsequently determined that they succumbed to a condition resembling congenital megacolon[16]. Mice with megacolon have difficulty extruding faeces through the most distal portion of their colon, resulting in a grossly distended bowel, compacted faeces and, in many cases, death. An example of this phenotype is illustrated in Fig. 4. This condition varied in severity and therefore most animals lived long enough to reproduce either on their own (occasional males) or via superovulation and embryo transfer. The original 1975-2 founder male eventually succumbed to megacolon when 11 months old.

Every transgenic animal examined in the 1975-2 lineage exhibited the megacolon phenotype. We have also observed the megacolon phenotype in two animals from the 1974-3 line and in four lines of transgenic mice carrying the 5 kb Hox-1.4-SV constructs. Preliminary observations on expression of the transgenes in one of these 5 kb lines have revealed elevated levels of *Hox-1.4* expression in the mid-gestation gut (data not shown). The megacolon phenotype varied in severity among the various lines, with the 1974-3 lineage rarely showing symptoms to one of the 5 kb Hox-1.4-SV lines in which all progeny carrying the transgene exhibited megacolon soon after birth and died before they were 10 days old. Multiple lines of transgenic animals exhibited a similar phenotype, indicating that the alteration in gut development was due to expression of the transgene, and not to a dominant insertional mutation.

There are several mouse mutant strains that exhibit megacolon as either homozygotes (for example, piebald lethal and lethal spotting[17]) or heterozygotes (dominant megacolon[18]). A congenital condition known as Hirschsprung's disease results in megacolon in man[19]. In each of these conditions the affected individuals exhibit a deficiency of myenteric ganglion cells in the colon[16]. These are neural crest derivatives that migrate into the developing gut to innervate the bowel[16]. The defect which results in megacolon may therefore be intrinsic to the neural crest cells; alternatively, the defect may lie in cells in the various layers of the developing gut that provide cues to the migrating neural crest cells. It is thus noteworthy that the *Hox-1.4* transgene is overexpressed in the mesenchymal layer of the day-12.5 embryonic gut of the transgenic mice.

It seems that the increased level of *Hox*-1.4 mRNA in the transgenic embryos is due to varying levels of elevated expression of the transgene at the appropriate sites, rather than to ectopic expression. Although there could be effects of the slightly elevated levels of *Hox-1.4* mRNAs in the lung and CNS, we have not observed any obvious developmental defects. In contrast, the development of megacolon in adult mice correlates with high levels of *Hox-1.4* transcripts in the embryonic gut and constitutes the first example of a mutant phenotype associated with the expression of a mammalian homoeobox-containing gene.

We wish to thank Mary Avarbock for technical assistance, George Grills for photographic assistance, and Carolyn Viviano, Zahra Zakeri, Patrick Burke and David Crotty for critical reading of the manuscript. This work was supported by grants from the NIH. R.D.P. is an Investigator of the Howard Hughes Medical Institute.

In vivo binding pattern of a *trans*-regulator of homoeotic genes in *Drosophila melanogaster*

Barbara Zink & Renato Paro

Zentrum für Molekulare Biologie, Universität Heidelberg, Im Neuenheimer Feld 282, D-6900 Heidelberg, FRG

The specification and maintenance of the metameric pattern in *Drosophila melanogaster* is regulated by complicated gene interactions. The differential expression of the homoeotic genes of the *Antennapedia* complex (ANT-C) and *bithorax* complex (BX-C), which determine segmental identities, is partly controlled by cross-regulatory interactions of loci within the two clusters and partly by *trans*-acting factors located outside the two complexes. One of the *trans*-regulatory genes, *Polycomb* (*Pc*), acts as a repressor of the ANT-C and BX-C[1–4]. Mutations of *Polycomb* result in a complete derepression of the homoeotic genes, leading to abdominal transformations of all body segments. *Polycomb* is part of a large class of *trans*-regulatory genes (*Pc*-group), estimated to comprise up to 40 loci[5]. We have raised antibodies against the Polycomb protein, and, using an improved immunostaining tech nique, showed that the Polycomb protein binds to 60 discrete sit along the polytene chromosomes of salivary glands. These sit comprise the ANT-C and the BX-C as well as several locatio of *Pc*-group genes. This is the first clear evidence for a dire interaction of *Polycomb* with homoeotic loci and other *Pc*-grou genes.

The *Polycomb* locus localizes to polytene chromosome ban 78 D 7,8. The DNA encompassing the gene has been cloned b a microdissection technique (R.P., J. Lauer and D. S. Hognes manuscript in preparation). About 4 kilobase (kb) of DN enclose the entire *Pc* locus, as shown by P-element-mediate germline transformation. *Polycomb* encodes three different tra scripts. Poly(A)$^+$ transcripts of 2.5 kb and 2.0 kb are very abu dant early in development (0–6-h-old embryos). The 2.5 kb RN is also transcribed during the remaining embryonic, larval an pupal stages, although at lower levels. A 1.0 kb transcript i especially abundant in late third instar larvae: in larval salivar glands it is the only *Pc* transcript found. Several complet cDNAs for the 2.5 kb transcript were isolated . Their sequenc reveals an open reading frame with a coding capacity for a 39 amino-acid Polycomb protein of relative molecular mass (M_r 44,000 (44K) (R.P. and D. S. Hogness, manuscript in prepar ation).

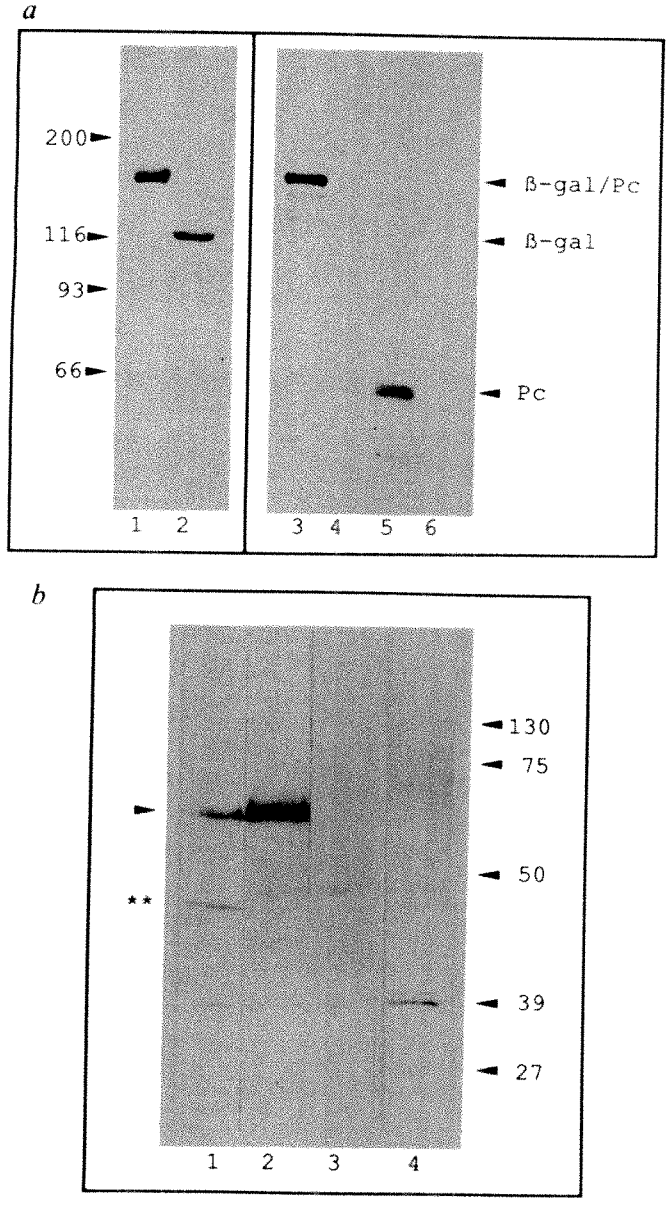

Fig. 1 Antibodies against the Polycomb protein. Polyclonal antibodies were raised against a lacZ–Pc fusion protein containing the C-terminal 199 amino acids of a Polycomb protein encoded by the 2.5 kb transcript. *a*, Lanes 1 and 2: partially purified βgal-Pc and βgal, respectively, were separated on a SDS-PAGE gel and stained with Coomassie Blue. Lanes 3 and 4: immunoblotted proteins equivalent to those in lane 1 and 2, respectively. Lane 5: a T5 expression vector (pUHE 21-3)[21] was used to express the authentic Pc protein in *Escherichia coli*. Crude extracts were separated on a SDS-PAGE gel and immunoblotted. Lane 6: immunoblotted crude *E. coli* extract harbouring the T5 vector only. Size markers are indicated on the left in thousands. *b*, *Drosophila* protein extracts were separated on SDS-PAGE gels and transferred to nitrocellulose. Western blots were incubated with purified polyclonal anti-Pc antibodies (lanes 1–3). Lane 1: extract from 150 third instar larval salivary glands. The lower band (**) shows the smaller, salivary gland-specific Pc protein. The 44K Pc protein is also visible (arrow), resulting from contaminating fat body cells (see also Fig. 2*a*). Lane 2: extract from 300 wild-type embryos staged between 18–22 hours. Only the predominant 44K Pc protein is visible. Lane 3: extract from 300 homozygous Pc^K-mutants staged between 18–22 hours, showing the absence of the specific 44K Pc band. The Pc^K-mutant was found to have a 2.0 kbp deletion in the Pc gene (R.P., J. Lauer & D. S. Hogness, manuscript in preparation). Lane 4: same extract as in lane 2 except that the western blot was incubated with the second antibody only. Size markers are indicated on the right, in thousands. The 44K Pc protein and presumably also the smaller Pc protein migrate aberrantly on a SDS-PAGE gel compared to the calculated M_r deduced from the cDNA sequence.

Methods. A 920-base pair (bp) cDNA fragment was cloned into the *Bam*HI site of pUR278 (ref. 22). BMH71-18 host cells were grown and induced as described[23]. The preparative purification of the 150K fusion protein was accomplished by urea extraction of the insoluble aggregate as described[23]. Out of one litre of culture we obtained 20–40 mg fusion protein, which was 90% pure. Rabbits were immunized with 100 μg fusion protein in PBS/complete Freund's adjuvant and boosted with 40 μg antigen in PBS/incomplete Freund's adjuvant. For the purification of anti-Pc antibodies crude antiserum was loaded on a β-galactosidase-Affigel 15 column (equilibrated in 0.1 M Tris-Cl *p*H 8). The flow-through was passed over a β-galactosidase-Pc-Affigel 15 column (equilibrated as above). This column was washed with 0.1 M Tris-Cl *p*H 8, 0.5 M NaCl. Antibodies were eluted with 0.1 M glycine-Cl *p*H 2.5. The specificity of the anti-Pc antibodies was checked by western blots of Pc proteins produced in *E. coli* (see Fig. 1*a*, lanes 3–6) and to *Drosophila* protein extracts (see Fig. 1*b*). *Drosophila* extracts were prepared as described[24].

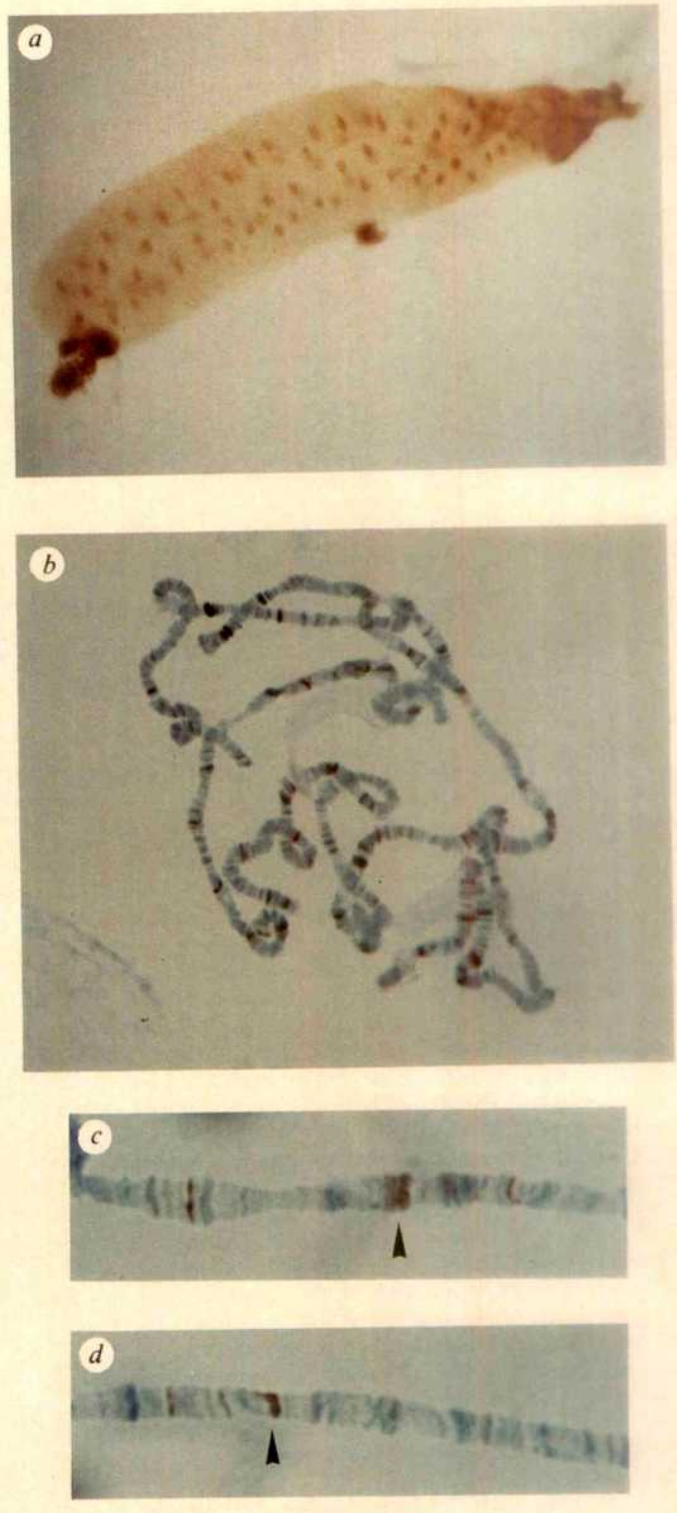

Fig. 2 Immunohistochemical localization of the Pc protein in salivary glands and on polytene chromosomes of third instar larvae. *a*, Single salivary gland showing intense staining of the large polytene nuclei. The tip of the gland shows strong staining of fat body cells. *b*, Immunostaining of squashed salivary gland chromosomes. The Pc protein is found associated with about 60 chromomeres (see Table 1) distributed over all chromosomes. No Pc protein is found in the centromere and in the nucleolus. *c*, Section of the 3rd chromosome showing the localization of the ANT-C (84 A 4,5–B 1,2; arrow). The most intense labelling is found in the distal portion of the complex (84 B 1,2). *d*, Section of the 3rd chromosome showing the association of Pc protein with the BX-C (89 E, arrow). The proximal-distal orientation of the chromosomes in *c* and *d* is from left to right.

Methods. Immunostaining of whole salivary glands. Salivary glands were dissected in PBS, 0.1% Triton X-100, fixed for 5 min in buffer A (100 mM HEPES *p*H 7.0, 2 mM $MgSO_4$, 1 mM EGTA) containing 1% formaldehyde. Glands were then washed several times with buffer A and then with BBT *p*H 7.0 (10 mM Tricine, 55 mM NaCl, 40 mM KCl, 7 mM $MgCl_2$, 5 mM $CaCl_2$, 20 mM glucose, 50 mM sucrose, 0.1% BSA, 0.2% Tween20). Glands were incubated for 1 h in BBT containing affinity-purified anti-Pc antibody, diluted to the desired concentration. Primary antibody incubation was followed by rinsing the glands in BBT. Then anti-rabbit IgG biotinylated antibody (preabsorbed to embryos; 1:1,000 dilution; Vector) in BBT, 1% normal serum was added for 40 min. Glands were then rinsed as above, followed by several short rinses in PBT (PBS, 0.1% Tween20). PBT was then replaced by PBT containing 1% reagent A (Avidin DH), 1% reagent B (biotinylated HRP) (both Vectastain ABC kit, Vector), which had been preincubated for 30 min. After a 40 min incubation the glands were washed again in PBT. Glands were stained with PBT, 0.005% DAB, 0.025% H_2O_2. The staining reaction was stopped by several washes in PBS. Salivary glands were mounted in 50% glycerol, PBS. Immunostaining of polytene chromosomes. Dissected salivary glands were transferred into a droplet of 3.7% formaldehyde, 1% Triton X-100, PBS *p*H 7.5 for 30 s. The glands were then moved in a 40 μl drop of 3.7% formaldehyde, 50% acetic acid on a coverslip for 2–3 min. Glands were squashed, the slides frozen in liquid nitrogen and the coverslip flipped off with a razorblade. The slides were rinsed in PBS, followed by BBT. The immunostaining procedure was essentially the same as for the glands. For all the incubation steps, the slides were kept in a humid atmosphere with a coverslip placed over the chromosomes. After immunostaining, chromosomes were stained for about 15 s in a 1:100 diluted Giemsa solution. After brief washing in distilled water, the chromosomes were embedded in 99.5% glycerol and immediately examined under the microscope. Photographs were taken on Kodak Ektachrome film using a Zeiss Axioplan microscope.

We have raised antibodies to the 199 C-terminal amino acids of the Polycomb protein. Polyclonal antiserum was purified and used to detect the protein in extracts of wild-type embryo (see Fig. 1*b* lane 2). The specificity of the antiserum is shown by the absence of the Pc protein band in western blots of extracts from mutant embryos (see Fig. 1*b*, lane 3). In addition, we have visualized the embryonic distribution of the Pc protein by immunostaining of whole mount embryos (B.Z. and R.P., manuscript in preparation). No immunostaining was seen in homozygous Pc^--mutant embryos (data not shown).

The expression of a specific *Pc* transcript in salivary glands of third instar larvae encouraged us to analyse this tissue for the presence of the Pc protein. Salivary glands contain large polytene chromosomes, which greatly facilitate the analysis of gene interactions. Figure 2*a* shows the specific labelling of the large nuclei of a salivary gland by the anti-Pc antibodies. The salivary gland-specific 1.0 kb transcript does not have sufficient coding capacity for a 390 amino-acid protein. It encodes a smaller Pc protein, which is also specifically recognized by the antiserum (Fig. 1*b*, lane 1). Spreading and immunostaining of the polytene chromosomes revealed that this Pc protein is associated with approximately 60 sites (Fig. 2*b* and Table 1). Cytological identification of the binding sites showed that Pc is associated with loci shown to interact with *Pc* by genetic methods (see Table 2). Pc protein is abundantly found at the ANT-C (84 A 4,5–B 1,2) and at the BX-C (89 E) (Fig. 2*c*, *d*). The strong

Suppressor of (*Pc*)[1]	21 AB	21 AB
Suppressor of (*Pc*)[2,3]	35 CD-38 B	35C+36 B
Suppressor of (*Pc*) (Brista^{MP})	60 D 14-E 2	60 E 1

Location of selected Pc binding sites that overlap with cytologically mapped genes with which Pc is interacting. Cytological positions (*) were taken from the following references: ANT-C (ref. 15); BX-C (ref. 1); *Asx*, *Psc* and *Scm* (ref. 5); *exd* (ref. 16); *polycombeotic* (A. Shearn, personal communication); *ph* (ref. 17); *sxc* (ref. 18); *E(Pc)* (ref. 8); *Su(Pc)*^{1,2,3} (ref. 9); *Su(Pc)(Brista*^{MP}) (refs 9, 19). 48A is also the location of the *engrailed* gene (ref. 20), as Pc was shown to interact with *engrailed* also (G. Morata, personal communication).

Pc antibody staining at the positions of these two complexes may reflect the regulatory activity of *Polycomb* on the large number of homoeotic genes located in these two clusters. In addition, Pc antibody staining is associated with several cytologically identified locations of *Pc*-group genes. Major exceptions were the *esc*[6] and the *Pcl*[7] loci, where there was no binding of the Pc protein. A very prominently labelled site was found at 49E 4-7, the presumptive location of *Psc*[5]. Pc labelling was also found associated with sites to which a third class of genes has been mapped[8,9]. These genes were found to interact with *Polycomb*, by either enhancing or suppressing the posterior transformations observed in *Pc*$^-$ mutants. They do not cause a *Pc*-like phenotype on their own, however, and their physiological function in development is unknown.

Table 2 shows the sites of Pc antibody labelling at locations of mapped genes, previously shown by genetic analysis to interact with *Pc*. The resolution of the cytological mapping is obviously limited by the size of the chromosomal aberrations used to define the location of a gene. Because the binding sites overlap with several members of a certain class, however, it is highly probable that Pc does indeed bind and regulate the genes indicated in Table 2.

Salivary glands are ectodermally-derived accessory organs of digestion and glue secretion, developing from an invagination of the labium[10]. No expression of homoeotic genes in this type of tissue has been reported so far. The presence of the Pc protein, acting as a repressor, would be consistent with this result. Although the binding pattern on polytene chromosomes of salivary glands can only represent the status of this particular tissue, genetic evidence has shown that Pc interacts with the same genes in other ectodermally-derived tissues[1-4,11-13]. This suggests that the pattern seen in salivary glands is unlikely to be completely different from that expected for other types of tissue. The terminal differentiation of larval salivary glands, which histolyse at metamorphosis, might indicate a default setting of *Polycomb*, keeping all homoeotic genes in a repressed state. At earlier developmental stages *Polycomb* might, with the help of different sets of *Pc*-like genes, repress homoeotic genes in a segment- and tissue-specific way.

This work demonstrates the first complete *in vivo* chromosome-binding pattern of an important regulatory factor involved in metameric development. We have shown that the Pc protein binds to genes shown genetically to interact with *Pc*. In addition we have identified the cytological location of other target genes of *Pc*. It will be interesting to define the integration of *Polycomb* in this complex regulatory network and to determine whether it acts as a negative regulator of the ANT-C and BX-C, but as an activator of other target genes. In addition it will be necessary to identify how *Pc* exerts its function at the molecular level: whether it regulates genes by acting as a DNA sequence-specific binding factor, or by recognizing other proteins (for example other Pc-group proteins) and interacting as a regulatory complex. To unravel the molecular mechanisms generating pattern formation in *Drosophila* it is necessary to identify as many of the components participating as possible. The use of cytology to study the complicated hierarchical gene interactions involved greatly facilitates this task. Moreover, the technique used here should prove valuable in the identification of target genes for other regulatory factors in *Drosophila* and, potentially, other regulatory elements from different biological systems that can be expressed in *Drosophila*.

We thank H. Saumweber for helpful advice in the preparation and fixation procedure of chromosomes, A. Kienlin and H. Jäckle for an introduction to immunostaining and I. Mattaj and T. Prospero for reviewing the manuscript. This work was supported by the Bundesministerium für Forschung und Technologie and by the Deutsche Forschungsgemeinschaft.

Granulocyte- and granulocyte–macrophage-colony stimulating factors induce human endothelial cells to migrate and proliferate

Granulocyte-colony stimulating factor (G-CSF) and granulocyte–macrophage-colony stimulating factor (GM-CSF) belong to a family of glycoprotidic growth factors required for the survival, growth and differentiation of haematopoietic precursors and which affect the function of circulating mature cells. They are produced by resting or stimulated stromal cells of the haematopoietic microenvironment (fibroblasts and endothelium) and by immunocompetent cells (T cells and monocytes/macrophages)[1,2]. The action of these CSF molecules was thought to be restricted to cells of haematopoietic origin. Here, we report that G-CSF and GM-CSF influence the migration and proliferation of human endothelial cells suggesting that these molecules may act as regulatory signals outside the haematopoietic system.

When different preparations of human recombinant G-CSF and GM-CSF were tested on human endothelial cells (HEC), a marked increase of migration across polycarbonate filters and incorporation in DNA of [^{3}H-methyl]thymidine ([^{3}H]thymidine) was observed (Fig. 1). Coating with gelatin of polycarbonate filters and plastic wells was necessary to observe HEC migration and [^{3}H]thymidine uptake in response to G-CSF and GM-CSF. Both factors acted in a dose-dependent way. The maximal response elicited by G-CSF and GM-CSF was somewhat lower in all experiments than that elicited by the optimal concentration of fibrinogen used as a chemoattractant in these studies[6] or by human recombinant basic fibroblast growth factor[7] used as growth factor (Table 1). HEC grown for 48 h in 1% fetal calf serum (FCS) with G-CSF or GM-CSF entered the S-phase within 8 h, measured by the incorporation of [^{3}H]thymidine and maximal incorporation occurred between 12 and 16 h, with lower values thereafter (data not shown). Increased DNA synthesis is coupled to a true HEC growth, with a two- to threefold increase in cell numbers after six days of culture with 140 and 250 pM G-CSF and GM-CSF, respectively (three experiments).

Cell proliferation is associated with the expression of a set of genes including c-*myc* and c-*fos*; c-*fos* is activated in response to chemoattractants[8], including G-CSF and GM-CSF[9]. Using northern analysis we detected a marked induction of c-*fos* mRNA in HEC (peak at 2 h) in the presence of cycloheximide (a superinducer of c-*fos* mRNA[10]).

In an attempt to identify the G-CSF and GM-CSF receptors on HEC that are responsible for the unexpected responses evoked by these cytokines in these non-haematopoietic cells, we studied the binding of ^{125}I-labelled molecules to HEC. Figure 2 shows representative experiments of the three performed for each cytokine. High-affinity binding sites were identified on HEC. The receptor number on the cell surface was estimated to be 356 ± 123 and 423 ± 187 with a dissociation constant (K_d) of 21 ± 8 pM and 54 ± 31 pM for G-CSF and GM-CSF, respectively (mean ± s.d. of three experiments). These values are of the same order of magnitude as those estimated for myelocytic or monocytic cells[11-13].

The unexpected effects of G-CSF and GM-CSF on the migration and proliferation of HEC could be due to contaminants present in the recombinant CSF preparations. The first indication that G-CSF and GM-CSF were indeed responsible for these activities was provided by the cytokine specificity of these effects. Monocytic-CSF (Fig. 1*a*) and interleukin 5 (IL-5) (Table 1), an

Table 1 The G-CSF and GM-CSF molecules are active in inducing HEC migration and proliferation

Agent	HEC migration (number of cells)	[^{3}H]thymidine incorporation (c.p.m. × 10^3)

Fibrinogen + anti-GM-CSF	104 ± 11	ND
Basic FGF (10 ng ml^{-1})	ND	39.12 ± 4.56*

Recombinant molecules were heat-inactivated by boiling for 10 min. Polymixin B (Sigma) was used at a concentration of 10 μg ml^{-1}. The mouse anti-human-G-CSF monoclonal antibody (mAb) 75A was from K. Welte and C. Bordingnon at a concentration of 8.2 mg ml^{-1} and a neutralizing activity of 33 U μg^{-1}. G-CSF (5 ng ml^{-1}) was preincubated with mAb (38 μg ml^{-1}) at room temperature for 40 min and then tested in a migration and [^{3}H]thymidine incorporation assay. Two different anti-GM-CSF antibody preparations were used in these experiments. The anti-human GM-CSF mAb used in migration experiments was from Dr Kurrle. GM-CSF (5 ng ml^{-1}) was preincubated with the anti-GM-CSF mAb (1.25 μg ml^{-1}) for 40 min at room temperature and then tested in the migration assay. A polyclonal rabbit anti-GM-CSF antibody (1:1,000 dilution) was used in proliferation experiments. The OKT11 mAb (Ortho) or mouse normal IgG were used as irrelevant IgG in these experiments. Human recombinant IL-1 was from Sclavo, Siena, Italy. Fibrinogen (from Dr E. Dejana) and human recombinant basic fibroblast growth factor (FGF) (Amersham) were used as reference agents active on HEC migration[6] and proliferation[7]. For basic FGF-induced [^{3}H]thymidine incorporation, the experiment was performed as described in the Fig. 1 legend, except that an incubation time of 48 h with the growth factor (optimal for FGF) was used. ND, not determined.
* $P < 0.05$ versus medium control.

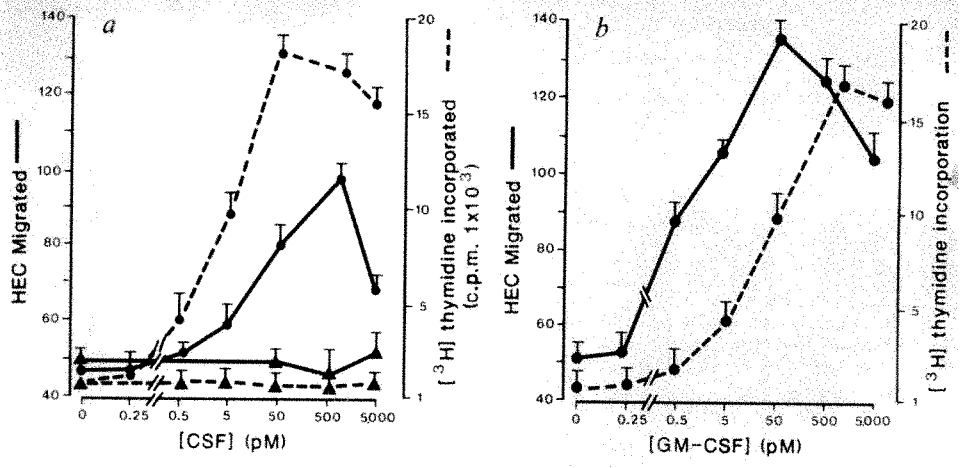

Fig. 1 Induction of HEC migration and proliferation by G-CSF (*a*, ●), monocytic-CSF (M-CSF, *a*, ▲) and GM-CSF (*b*, ●).

Methods. From the human umbilical vein, HEC (III–VIII passage) were cultured as described[3]. The cells (2×10^4 per well, 24 well plates precoated with 0.05% gelatin for 24 h) were grown for 24–36 h in M199 with 20% FCS and then starved for 48 h in 1% FCS with 0.5% bovine serum albumin (BSA, fraction V, Sigma). Medium was then removed and replaced with control medium containing 2% FCS with or without recombinant G-CSF (Dr T. Okabe, 7.8×10^7 U ml^{-1}; or Amgen, 1.5×10^8 U mg^{-1}), GM-CSF (Genetics Institute; or Behringwerke; or Immunex, 10^7 U mg^{-1}) and M-CSF (Cetus, 4×10^7 U mg^{-1}). The cells were incubated for 11 h at 37 °C, [^{3}H-methyl]thymidine (0.5 μCi; 30 Ci mmol^{-1}, Amersham) was added and incubation continued for 1 hour. Medium was removed, cells were washed twice and detached by trypsinization. DNA was precipitated with 10% cold trichloroacetic acid and collected on 0.2 μm Gelman filters[4]. Radioactivity was measured by liquid scintillation counting. Results presented are the mean ± s.d. of three experiments in triplicate. Chemotaxis experiments were performed with a 48-well modified Boyden chamber technique[5,6]. Polycarbonate filters (5 μm pore size, polyvinylpyrrolidone-free) were soaked in 0.5 M acetic acid, washed with PBS, incubated for 24 h in 0.01% gelatin (Sigma) and air-dried. G-CSF, GM-CSF and M-CSF (25 μl) in M199 containing 0.2% BSA were seeded in the lower compartments and 50 μl of HEC (2×10^6 ml^{-1}) were added in the upper ones. After 6 h incubation at 37 °C, the upper surface of the filter was scraped with a rubber policeman. The filters were fixed and stained, and five oil immersion fields (lower surface) were counted after coding the samples. Results are presented as mean ± s.d. migrated cells (statistical significance assessed) by Dunnet's test. Results presented are from individual experiments out of nine (GM-CSF) or three (G-CSF, M-CSF).

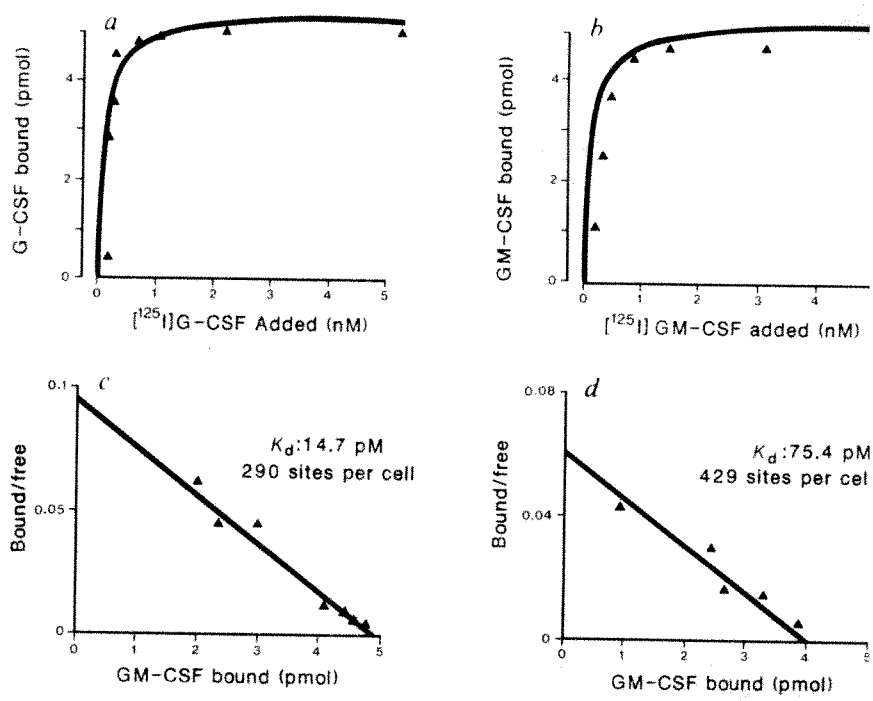

Fig. 2 G-CSF and GM-CSF receptors on HEC. *a*, *b*, Saturation curve at equilibrium: *c*, *d*, Scatchard representation of the specific binding.

Methods. Binding experiments have been performed by using [^{125}I] G-CSF and [^{125}I] GM-CSF. G-CSF and GM-CSF (30 μg per 20 μl borate buffer 0.1 M, *p*H 8) were iodinated using Bolton-Hunter reagent (Amersham; 0.5 mCi for each cytokine). Labelled cytokines were passed througyh Sephadex G-25. The specific activity of the radiolabelled G-SCF (6 ng per 10^5 c.p.m.) and GM-CSF (7.4 ng per 10^5 c.p.m.) was assessed by measuring protein concentration. Iodinated cytokines are active on HEC in terms of migration and proliferation. HEC were detached from the plastic flasks by incubation for 10 min at 37 °C in PBS containing 1 mM [ethylenebis(oxyethylenenitrilo)] tetraacetic acid and then washed twice in medium 199 containing 25 mM (4-(2-hydroxyethyl)-1-piperazinoethanesulphonic acid, *p*H 7.4 and 0.2% BSA (binding buffer). Cells (4×10^6; 95–97% viable) in 0.4 ml of binding buffer containing different concentrations of labelled G-CSF and GM-CSF, with or without 100-fold excess of unlabelled cytokines, were incubated for 2 h at 23 °C. In preliminary experiments, binding at 23 °C required 2 h to reach the equilibrium for both cytokines. The reaction was stopped by centrifugation of the cells, which were overlayered onto 0.8 ml of cold binding buffer containing 75% FCS[11] and the radioactivity in the pellet was determined. Specific binding was determined as the amount of binding inhibited by 100-fold excess of the unlabelled G-CSF or GM-CSF. Binding data were analysed by nonlinear least squares curve fitting with ENZFITTER program (IBM). Data shown are representative of three different experiments done in triplicate.

eosinophil CSF[14], had no effect on the migration and proliferation of HEC. Similarly, IL-1, a molecule active on haematopoietic progenitors[15] and with profound effects on HEC function[16], did not induce HEC migration (Table 1). Thus, the capacity to elicit a migratory and proliferative response in HEC is not shared by all recombinant molecules active on haematopoietic precursors, even when these cytokines, like IL-1, profoundly affect other HEC functions. Polymixin B which inhibits bacterial lipopolysaccharides, did not affect the activity of G-CSF and GM-CSF (Table 1). Boiling abolished the activity of G-CSF and GM-CSF (Table 1). Anti-G-CSF and anti-GM-CSF antibodies abolished the induction of HEC functions (Table 1). Irrelevant control antibodies were inactive and the inhibitory effect of specific antibodies did not seem to be due to non-specific effects, as there was no effect on the activity of fibrinogen. We also tested the possibility that a non-HEC cell

Different concentrations of GM-CSF were placed in the upper and/or lower compartments of the chemotaxis chamber. Results are expressed as the number of migrated HEC (mean ± s.d. of three samples for each experimental point).

* $P < 0.05$ versus medium control.

contaminant (that is, monocytes), might directly or indirectly account for the actions of G-CSF and GM-CSF on HEC. HEC cultures consisted of homogeneous cells with typical cobblestone morphology, having (>99%) granular deposits of factor VIII antigen, as well as H-lectin antigen and class I, but not class II, histocompatibility antigens on the surface. We could not detect cells expressing CD11b, CD14 or CD3 with flow cytometry. Treatment with anti-CD11b or anti-CD3 and complement did not affect the responses of HEC to the two CSF. The human endothelial cell line EAhy926 (refs 17–19) migrated and expressed c-*fos* mRNA after stimulation with G-CSF and GM-CSF and had specific receptors for these molecules (data not shown). Collectively, these data showed that HEC do indeed have receptors for and respond to G-CSF and GM-CSF.

In checkerboard experiments[6], maximal induction of migration across filters occurred in the presence of a positive concentration gradient between the lower and upper compartments of the chamber (Table 2). With equal concentrations of GM-CSF above and below the filter, a smaller, but significant enhancement of HEC migration was observed, suggesting that there is a chemokinetic component, in addition to chemotaxis, in the action of GM-CSF on HEC locomotion. G-CSF and GM-CSF also induced migration when HEC had adhered to the filters before the assay, excluding the possibility that these cytokines were merely affecting the speed of adhesion of HEC to filters.

The results presented here demonstrate that G-CSF and GM-CSF induce migration and proliferation of HEC, in what we believe is the first demonstration of activity of these molecules on non-haematopoietic cells. Other examples, of leukocyte-specific non-pleiotropic cytokines acting on non-hematopoietic elements, are monocytic-CSF acting on trophoblast cells and IL-2 acting on glial cells[20,21]. Our observation is interesting in the light of the many similarities between myelomonocytic cells and endothelium, illustrated by previously widespread use of the expression 'reticuloendothelial system'.

G-CSF and GM-CSF are produced by various cell types including stimulated lymphocytes, activated macrophages[1,2] and endothelial cells exposed to monokines[22,23]. Il-1 has been reported to induce proliferation of vascular elements[24] and c-*fos* expression in HEC[25]. The functionally related monokine tumour necrosis factor, however induces the migration of endothelial cells[26], but inhibits their proliferation[27]. These monokines do, however, elicit a complex set of responses in HEC, which include CSF production. For example, IL-1-induced proliferation of vascular smooth muscle is masked by the concomitant induction of growth inhibitory prostaglandins[24]. Proliferation of endothelial cells and neovascularization occur at sites of cell-mediated immunity and inflammation[28] and locally produced G-CSF and GM-CSF may be one of the factors involved in the fine regulation of the proliferation and migration of endothelium. Survival and growth of endothelium in bone marrow stroma is essential for the haematopoietic microenvironment and haematopoiesis. The capacity of appropriately stimulated HEC to produce G-CSF and GM-CSF suggests that these molecules may participate in autocrine regulation of function.

We thank Drs E. Dejana, F. Seiler and D. Krumvieh for discussion and criticism. The recombinant CSF molecules were gifts of Drs S. C. Clark, S. Gillis, D. Krumvieh, T. Okabe, P. Ralph and L. Souza. This work was supported by the Special Project Oncology and by Special Project Biotechnology from CNR, Rome, Italy and by the Italian Association for Cancer Research.

Peptidyl-prolyl *cis-trans* isomerase is the cyclosporin A-binding protein cyclophilin

Nobuhiro Takahashi, Toshiya Hayano & Masanori Suzuki

Corporate Research and Development Laboratory, Toa Nenryo Kogyo K. K., 1-3-1 Nishi-tsurugaoka, Ohi-machi, Iruma-gun, Saitama 354, Japan

Peptidyl-prolyl *cis-trans* isomerase (PPIase) catalyses the *cis-trans* isomerization of proline imidic peptide bonds in oligopeptides and has been shown to accelerate the refolding of several proteins *in vitro*[1–4]. Its activity has been detected in yeast, insects and *Escherichia coli* as well as in mammals, and it is thought to be essential for protein folding during protein synthesis in the cell[1]. We purified PPIase from pig kidney and found that its amino-acid sequence is identical to that reported for bovine cyclophilin, a protein known to bind the immunosuppressive drug, cyclosporin A (ref. 5). To investigate the functional relationship between

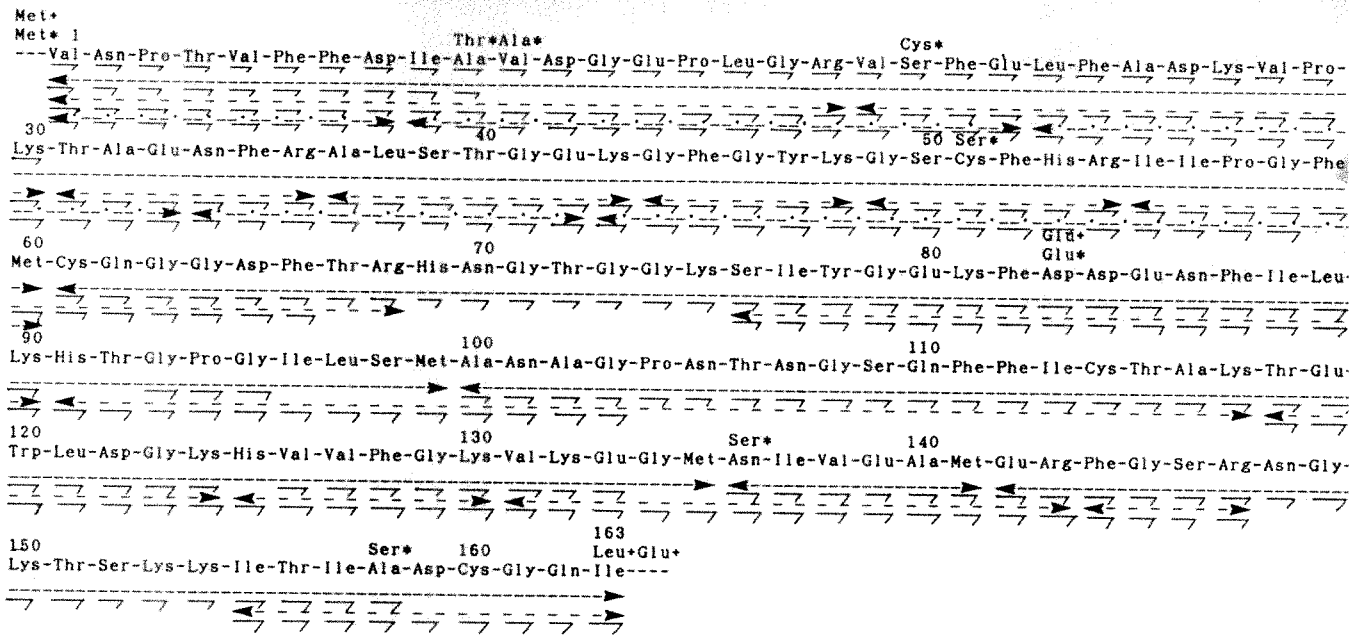

Fig. 1 Amino-acid sequence of form *a* of pig PPIase. The peptides from which the sequence was derived are as follow: - - -, tryptic peptides; - - - -, cyanogen bromide peptides; and —·—·—, *Staphylococcus aureus* V8 protease peptides of the amino-terminal cyanogen bromide peptide. After digestion of the native protein with either trypsin or cyanogen bromide, the peptides containing Cys 61 and Cys 160 purified as single peaks which could be separated further (to give the tryptic peptides 55–68 and 155–163, or the cyanogen bromide peptides 61–99 and 142–163) on reduction and carboxymethylation, indicating the existence of a disulphide bond. In contrast the peptides containing Cys 51 and Cys 114 purified separately, even without alkylation and reduction. The arrows at the amino terminus and under each peptide line indicate sequenator analyses of the intact form *a* and the peptides obtained. Differences between the pig and the rat, and/or the human sequences are indicated above the corresponding residues and designated by * for rat and by + for human. The amino-acid sequences of rat and human were deduced from their cDNA sequences[7,8].

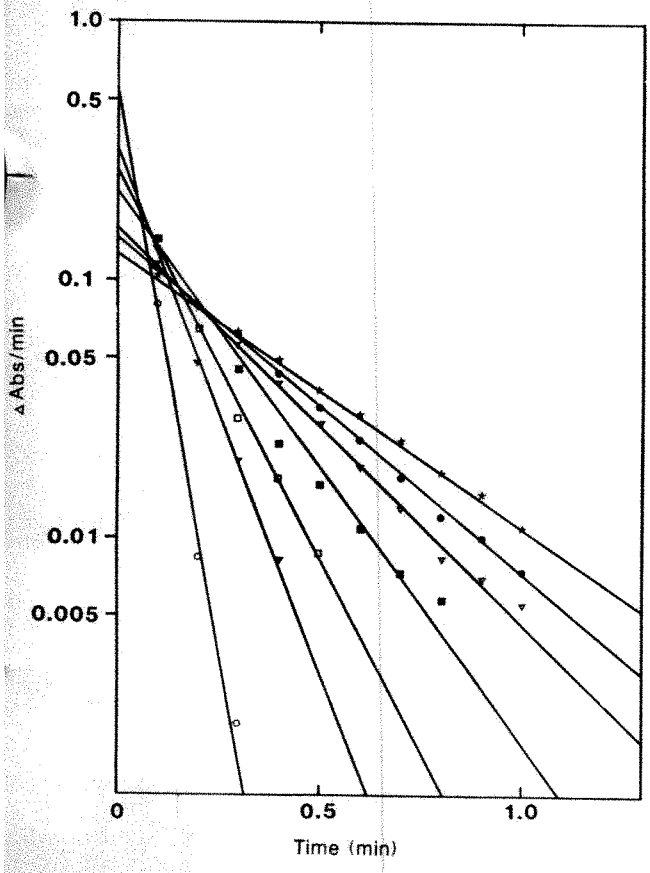
Methods. The amino-acid sequence analysis was carried out by automated Edman degradation using Applied Biosystems 477A protein sequencer equipped with a model 120A on-line PTH analyser. The native protein (20–100 μg) was subjected to separate digestions with L-1-tosylamido-2-phenylethyl chloromethyl ketone-treated trypsin, and cyanogen bromide. The digests were separated on an Aquapore RP-300 column or on a Spheri-5RP-18 column with the use of 130A separation system (Applied Biosystems). The columns were eluted at a flow rate of 200 μl min^{-1} with a linear gradient of acetonitrile (0–100%) containing 0.1% trifluoroacetic acid or 0.1% heptafluorobutylic acid for 45 min. The amino-terminal cyanogen bromide peptide was further digested with *Staphylococcus aureus* V8 protease. Amino-acid analysis was carried out by Beckman 6300 E amino-acid analyser after hydrolysis with 6 M HCl for 24 h.

PPIase and cyclophilin we examined the effect of cyclosporin A on PPIase activity and found that it was inhibitory. Thus we propose that the peptidyl-prolyl *cis-trans* isomerizing activity of PPIase may be involved in events, such as those occurring early in T-cell activation, that are suppressed by cyclosporin A.



We detected PPIase activity, by the assay described in the Fig. 2 legend, in a crude ammonium sulphate extract prepared from pig kidney[1]. PPIase was purified further as described in Table 1, and after a final step of purification by reversed-phase column chromatography, was separated into two forms (*a* and *b*). These isoforms have an apparently identical relative molecular mass (M_r) of 18,000 and very similar amino-acid compositions (data not shown). Although the observed relative molecular mass is somewhat at variance with the value previously reported ($M_r = 14,000$)[3] we were not able to detect any other major component with PPIase activity during the purification. Exposure to a high concentration of acetonitrile during the reversed-phase column chromatography decreased but did not eliminate the specific activity detected (Table 1).

The two isoforms *a* and *b* were present in a ratio of 53:47 and their specific PPIase activities were indistinguishable. A comparison of their tryptic peptide maps indicated that the structural difference between the two isoforms resides in the amino-terminal peptides (data not shown). The first 30 amino-acid residues of form *a* were unambiguously determined by Edman degradation (see Fig. 1) but the amino terminus of form *b* could not be sequenced using this method.

Sequence analysis of form *a* reveals a total of 163 amino-acid residues and predicts a relative molecular mass of 17,735, in good agreement with the estimate by SDS-gel electrophoresis. Peptide mapping data indicate the existence of a disulphide bridge between Cys 61 and Cys 160, although we cannot exclude the possibility that this was formed *in vitro*, as we did not use anti-oxidant during the purification procedure. The remaining two cysteine residues, Cys 51 and Cys 114 (see Fig. 1 legend) appear to have free sulphydryl groups.

On searching for homologous sequences in the National Biomedical Research Foundation database, we found that the sequence of pig PPIase is identical to that of bovine cyclophilin. Cyclophilin is known to bind specifically to cyclosporin A (CsA), a cyclic undecapeptide of fungal origin, that is a potent immunosuppressant used to prevent rejection on transplantation of organs such as kidney, heart, bone marrow and liver[5,6]. Cyclophilin is a soluble cytosolic protein and is present in high concentrations (0.1–0.4% of total cytosolic proteins) in many mammalian tissues[5,6] and in nearly all organisms[5–7]. Two isoforms have been isolated for bovine cyclophilin and are expected to have very similar molecular structures[6].

The amino-acid sequence of pig PPIase (and bovine cyclophilin) is 96% identical to the published sequences for rat[7] and human[8] cyclophilin, and about 60% identical to the recently published sequence for *Neurospora crassa*[9], indicating a high degree of conservation across species. PPIase was suggested to be present on ribosomal particles[1] and it is interesting that

◀ **Fig. 2** Inhibition of PPIase activity by CsA. The kinetics of *cis-trans* isomerization of *N*-succinyl-Ala-Ala-Pro-Phe-MCA was monitored at 360 nm in a coupled assay with chymotryptic cleavage. The MCA moiety can only be cleaved off by chymotrypsin when the preceding Ala-Pro peptide bond is in the *trans* conformation[1]. At the equilibrium about 12% of the peptide has a *cis* Ala-Pro bond. In the presence of a high chymotrypsin concentration, hydrolysis of the *trans* peptide occurs within a few seconds, but cleavage of the *cis* peptide is limited in rate by the *cis* → *trans* isomerization of the Ala-Pro bond. The *trans* peptide was cleaved within the deadtime and the kinetic data of this phase is not shown. The rate of *cis* → *trans* isomerization of *N*-succinyl-Ala-Ala-Pro-Phe-MCA, represented as the absorbance change at a given time (ΔAbs/min) is plotted against the proceeding times (min) in semi-logarithmic plots. CsA clearly affected the rate of the isomerization catalysed by PPIase: ○, without CsA; ▼, 0.04 μg; □, 0.08 μg; ■, 0.16 μg; ▽, 0.4 μg; ●, 1 μg and ★, without PPIase.
Methods. Aliquots (2.0 ml) of 0.035 M HEPES-buffer containing 5 mM 2-mercaptoethanol, pH 7.8, were incubated at 25 °C for 10 min in the spectrophotometer cell (Spectrophotometer U-3210 with temperature controller SPR-7 and cell stirrer, Hitachi) before adding 50 μl 1.68 mM *N*-succinyl-Ala-Ala-Pro-Phe-MCA in the same buffer. Samples were equilibrated for 1 min. The PPIase fraction (0.27 μg) was incubated with the substrate for 30 s and the reaction was started by adding 20 μl 0.76 mM of chymotrypsin (sigma). The effect of CsA on PPIase activity was examined by mixing CsA with PPIase for 1 min before incubating with the substrate. CsA was kindly provided by Dr Y. Yamakawa of the National Institute of Health, Japan and was dissolved in saline containing 7% ethanol and 2.85% Tween 80 before use (this solvent did not affect the PPIase activity measured in these experiments). The rate of isomerization at a given time was calculated by using a rate assay program provided for Spectrophotometer U-3210.

Table 1 Purification of pig kidney PPIase

Purification step	Total protein (mg)	Total activity (arbitrary units)	Specific activity (arbitrary units mg^{-1})	Activity recovery (%)
Ammonium sulphate fraction	7,322	183,050	25	100
DEAE-Sephacel chromatography	699	90,222	129	49
Sephacryl S-200 gel filtration	67	63,784	952	35
Sephadex G-75 gel filtration	6.7	37,218	5,555	20
TSK-phenyl 5PW-RP chromatography				
form *a*	1.4	1,417	1,012	1
form *b*	1.2	1,368	1,146	1

The ammonium sulphate extract containing PPIase activity was prepared from 690 g of pig kidney cortex by the method of Fischer *et al.*[1]. The extract was dialysed against 0.01 M Tris-HCl buffer, pH 8.0, containing 0.05% NaN_3 and applied to a DEAE-Sephacel column (2.5 cm ID × 35 cm). PPIase activity was measured in a coupled assay with chymotrypsin by a modified method of Fischer *et al.*[1] in which the oligopeptide *N*-succinyl-Ala-Ala-Pro-Phe-4-methyl-coumaryl-7-amide (MCA) (Peptide Institute Inc., Osaka, Japan) was used as the substrate instead of *N*-succinyl-Ala-Ala-Pro-Phe-*p*-nitroanilide[4] or glutaryl-Ala-Ala-Pro-Phe-4-nitroanilide[1]. The eluate rich in PPIase activity passed through the column and was obtained as a single peak, which was concentrated by ammonium sulphate fractionation and separated on a Sephacryl S-200 column (2.5 cm ID × 90 cm) equilibrated with 0.1 M Tris-HCl buffer, pH 8.0, containing 0.15 M NaCl and 0.05% NaN_3. A major PPIase activity was found in the last peak and this fraction was rechromatographed on a Sephadex G-75 column (2.5 cm ID × 90 cm). Finally, PPIase was purified by reversed-phase chromatography on a TSK-phenyl 5PW-RP column with a linear gradient of acetonitrile (0–70%) containing 0.1% TFA, and eluted as two peaks at about 40% of acetonitrile concentration. Although the specific activity of PPIase was decreased by one-fifth after the reversed-phase chromatography, it was associated with only the peaks of $M_r = 18{,}000$.

cyclophilin was found to be localized in both the mitochondria and the cytosol of *Neurospora crassa*[9].

The CsA-binding activity of cyclophilin is sulphhydryl dependent[5] and the activity of PPIase is also affected by sulphhydryl blocking reagents[1], suggesting that CsA binding may modulate PPIase activity. We therefore examined the effect of CsA and found that it blocked PPIase activity (Fig. 2). Activity was almost completely inhibited in the presence of CsA at 3×10^{-7} M, a concentration that is consistent with the dissociation constant of CsA to cyclophilin (2×10^{-7} M; ref. 5). These results, and the observation that both PPIase activity and the CsA-binding activity of cyclophilin are heat-sensitive at around 50 °C, and abolished by incubation with trypsin but not with chymotrypsin[1,6], support, on functional grounds, the identity between PPIase and cyclophilin.

On the basis of this identity, we propose that CsA may mediate some of its effects, such as the inhibition of interleukin-2 and γ-interferon production during T-lymphocyte activation, via its inhibitory action on PPIase. We also propose that PPIase may act, not only as an enzyme that facilitates folding during protein synthesis, but as a fundamental modulator in various intracellular signal transduction processes, though *cis-trans* isomerization of the partner molecules. The ubiquitious presence of PPIase, coupled with what we know of the effects of CsA-binding, may be indicative of its significance in such biochemical processes.

The enzyme peptidyl-prolyl *cis-trans* isomerase (PPIase) was recently discovered in mammalian tissues and purified from porcine kidney[1]. It catalyses the slow *cis-trans* isomerization of proline peptide (Xaa-Pro) bonds in oligopeptides and accelerates slow, rate-limiting steps in the folding of several proteins[2-5]. Here, we report the N-terminal sequence of PPIase together with further chemical and enzymatic properties. The results indicate that this enzyme is probably identical to cyclophilin, a recently discovered mammalian protein which binds tightly to cyclosporin A (CsA). Cyclophilin is thought to be linked to the immunosuppressive action of CsA[6-11]. The first 38 amino-acid residues of porcine PPIase and of bovine cyclophilin are identical and the two proteins both have a relative molecular mass of about 17,000 (ref. 7). The catalysis of prolyl isomerization in oligopeptides and of protein folding by PPIase are strongly inhibited in the presence of low levels of CsA. The activities of both PPIase and cyclophilin depend on a single sulphydryl group. At present it is unknown whether the inhibition of prolyl isomerase activity is related with the immunosuppressive action of CsA.

PPIase from pig kidney was subjected to automated N-terminal sequence analysis. The first 38 amino-acid residues of porcine PPIase are shown in Table 1. The sequence is identical to the N-terminal sequences of cyclophilin from human spleen and from bovine thymus[7,10]. An analysis[12,13] of the fluorescence and of the absorbance spectra of PPIase yields a content of one tryptophan and two tyrosine residues per PPIase molecule, which agrees with the respective values found for the cyclophilins[7,10]. Porcine PPIase and bovine cyclophilin[7] show the same apparent relative molecular mass (M_r) of 17,000 (17K). From the sequence analysis the actual M_r is 17,737, corresponding to 163 residues[7].

Cyclophilin forms very tight stoichiometric complexes with CsA. Values in the range of 5-200 nM were estimated for the respective dissociation constants[6,7]. CsA binds efficiently to PPIase as well. In the presence of CsA both catalysis of *cis-trans* isomerization of a proline-containing oligopeptide and the acceleration of protein folding are inhibited. The inhibition of the activity towards the peptide Suc-Ala-Ala-Pro-Phe-4-nitroanilide is shown in Fig. 1*a*. The rate of *cis* → *trans* isomerization of the Ala-Pro bond is increased from $k = 7.4 \times 10^{-3}\ s^{-1}$ (in the absence of PPIase) to $k > 1\ s^{-1}$ in the presence of 0.19 μM PPIase. Addition of 7 μM CsA abolishes the accelerating effect of PPIase and decreases the reaction rate to a value ($k = 9.0 \times 10^{-3}\ s^{-1}$) that is similar to the uncatalysed isomerization. The interaction is reversible: diluting out CsA by 2,000-fold restores PPIase activity. Figure 1*b* shows the decrease of PPIase activity with increasing concentrations of CsA. The resulting inhibition constant ($K_i = 2.6$ nM) agrees fairly well with the lower limit given for the dissociation constant ($K_d = 5$-200 nM) of the cyclophilin/CsA complex determined under different conditions[7].

The catalysis of slow protein folding reactions by PPIase is inhibited in the presence of CsA as well (Fig. 2). Slow refolding of ribonuclease T1 is strongly accelerated in the presence of 0.35 μM PPIase. Addition of 1.0 μM CsA inhibits catalysis of folding completely and a >95% inhibition of the PPIase activity towards folding of RNase T1 is found already in the presence of 0.5 μM CsA.

Both the binding of CsA to cyclophilin[8] and the catalysis of proline isomerization by PPIase[1] are sulphydryl dependent. One sulphydryl group of PPIase is specifically protected against modification with *p*(hydroxymercuri)-benzoate (*p*HMB) when CsA is bound to the enzyme. In the absence of CsA the modification reaction is triphasic. After a fast reaction with *p*HMB two slow phases are observed in which two and one sulphydryl group per PPIase molecule, respectively, are modified (Fig. 3*a*). The slowest phase is not observed in the presence of CsA. Apparently binding of CsA protects the most

Table 1 Determination of the N-terminal sequence of PPIase from porcine kidney

Cycle no.	Amino acid	Amount* (pmol)	Cycle no.	Amino acid	Amount* (pmol)	Cycle no.	Amino acid	Amount* (pmol)

PPIase was isolated from pig kidney cortex. After a 40-60% ammonium sulphate fractionation the protein was applied on a Sephadex cation exchange column at *p*H 8.5 and eluted with a linear KCl gradient (0-0.4 M). This was followed by gel filtration over Sephadex G-75 and chromatography on phenyl Sepharose or Fractogel TSK AF blue. The procedure resulted in a 780-fold purification and yielded material that migrated as a single 17 K band on denaturing polyacrylamide gels under reducing conditions. The N-terminal sequence was determined by automated Edman degradation using a 477A sequencer and an on-line 120A PTH analyser (both from Applied Biosystems). In addition to the 17 K PPIase, additional active protein species can be isolated which differ in M_r and isoelectric point. They will not be discussed further here.

* Yield of PTH amino acids at each step of the sequence analysis.

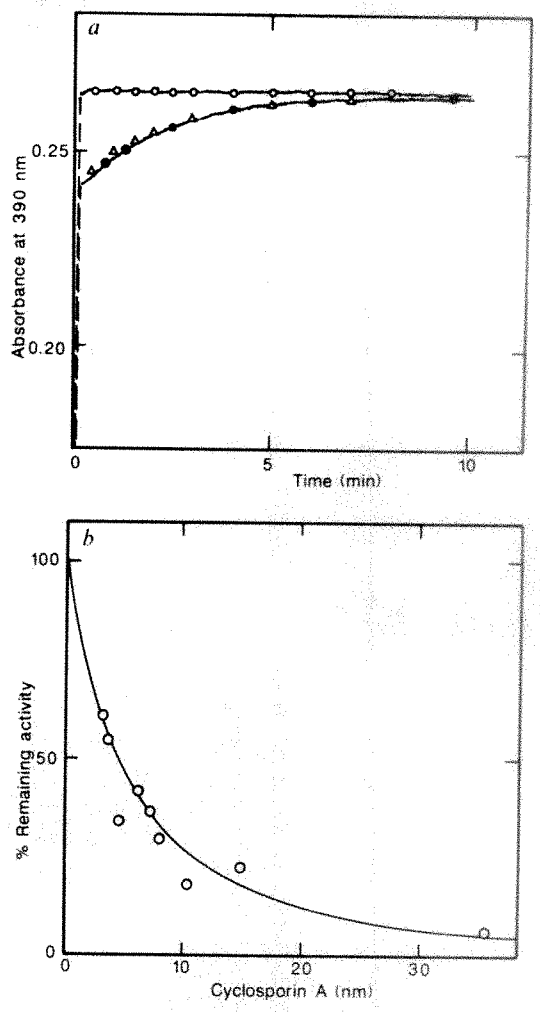

Fig. 1 Inhibition of PPIase by cyclosporin A. The activity of PPIase was determined by measuring the catalysis of the *cis* → *trans* interconversion of *cis* Suc-Ala-Ala-Pro-Phe-4-nitroanilide. *a*, *Cis* → *trans* isomerization (●) in the absence of PPIase ($k = 7.4 \times 10^{-3}\ s^{-1}$); (○) in the presence of 190 nM PPIase ($k > 1\ s^{-1}$); (△) in the presence of 190 nM PPIase + 7 μM CsA ($k = 9.0 \times 10^{-3}\ s^{-1}$). The *cis* content of the substrate remained unaffected by the presence of CsA. *b*, Dependence of residual PPIase activity on CsA concentration. 3.1 nM PPIase were preincubated in the presence of varying concentrations of CsA and the remaining PPIase activity was determined. The substrate concentration was much smaller than K_M, therefore no deviation from first-order kinetics were observed in the presence of the inhibitor CsA. An inhibition constant $K_i = 2.6 \pm 0.4$ nM can be calculated from the data.
Methods. The *cis* → *trans* isomerization of the Ala-Pro peptide bond in the test peptide N-succinyl-Ala-Ala-Pro-Phe-4-nitroanilide was measured in a coupled assay with chymotrypsin (Serva, Heidelberg), based on the ability of this protease to cleave the test peptide only when the Ala-Pro is *trans*[1,17]. α-Chymotrypsin (21 μM) was preincubated with the appropriate concentrations of PPIase and CsA and the assay was started by manual mixing with 30 μl of the test peptide in the spectrometer cell at 10 °C (the final concentration of test peptide was 22 μM). The *trans* peptide was cleaved within the deadtime; hydrolysis of the 4-nitroanilide in the *cis* peptide is limited in rate by the *cis* → *trans* isomerization at Ala-Pro and was followed by the increase in absorbance at 390 nm.

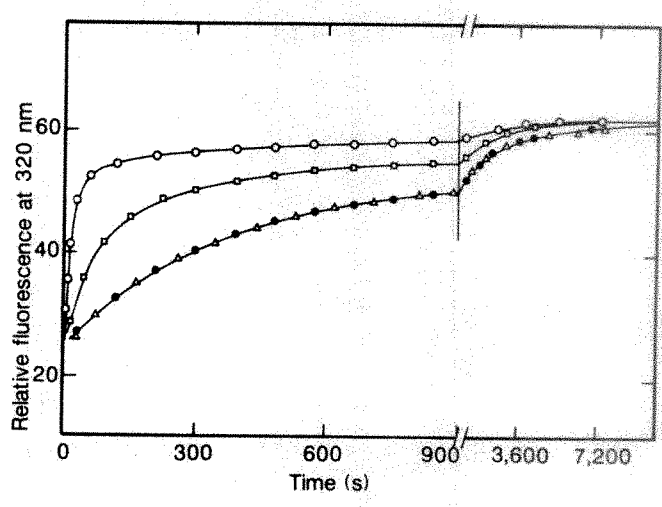

Fig. 2 Inhibition by CsA of the catalytic effect of PPIase on slow protein folding of RNase T1. The increase in fluorescence at 320 nm is shown as a function of the time of refolding in the absence of PPIase and CsA (●); in the presence of 0.35 μM PPIase (○); in the presence of 0.35 μM PPIase and 1.0 μM CsA (△); and in the presence of 0.35 μM PPIase and 0.5 μM CsA (□).
Methods. Recombinant RNase T1 was a gift from U. Hahn (Berlin). Unfolded protein was generated by a 2 h incubation of 13 μM RNase T1 in 8.0 M urea, 0.1 M Tris-HCl, *p*H 8.0 at 25 °C. Refolding was initiated by diluting 25 μl of the unfolded protein with 975 μl of 0.1 M Tris-HCl containing appropriate amounts of PPIase and CsA in the spectrophotometer cell at 10 °C. The final conditions for refolding were 0.33 μM RNase T1 in 0.2 M urea, 0.1 M Tris-HCl, *p*H 8.0 at 10 °C. Refolding was monitored by the increase in fluorescence at 320 nm (5 nm slit). Excitation was at 268 nm (5 nm slit). A Perkin-Elmer LS-5B fluorescence spectrophotometer was used.

owly reacting cysteine residue of PPIase against modification ith *p*HMB. Furthermore, completely SH-blocked PPIase no nger binds CsA, as could be shown in partition experiments f CsA between native PPIase and a large excess of the modified rotein. The inactivation by *p*HMB (Fig. 3*b*) and the odification of the least accessible cysteine (Fig. 3*a*) show very milar kinetics, indicating that this cysteine is directly involved the catalytic reaction of PPIase. In addition, binding of CsA hibits the irreversible inactivation by *p*HMB (Fig. 3*b*). A netic deuterium isotope effect, observed when α-C deuterated aa amino acids in -Xaa-Pro- containing peptides are used as substrates for PPIase[14], suggests that the substrate is covalently attached to the enzyme in the course of catalysis, probably as a hemithioorthoamide, which would allow free rotation about the C–N bond.

We conclude from these data that cyclophilin and PPIase are closely related or identical proteins. Both are widely distributed in different organisms and cell types[9]; they are abundant (cyclophilin 0.1–0.4%, PPIase 0.4% of total protein[7,15]), and they occur in different forms or isoenzymes (refs 6, 7 and unpublished observation by G. Fischer). The wide distribution of PPIase/cyclophilin and the highly conserved primary

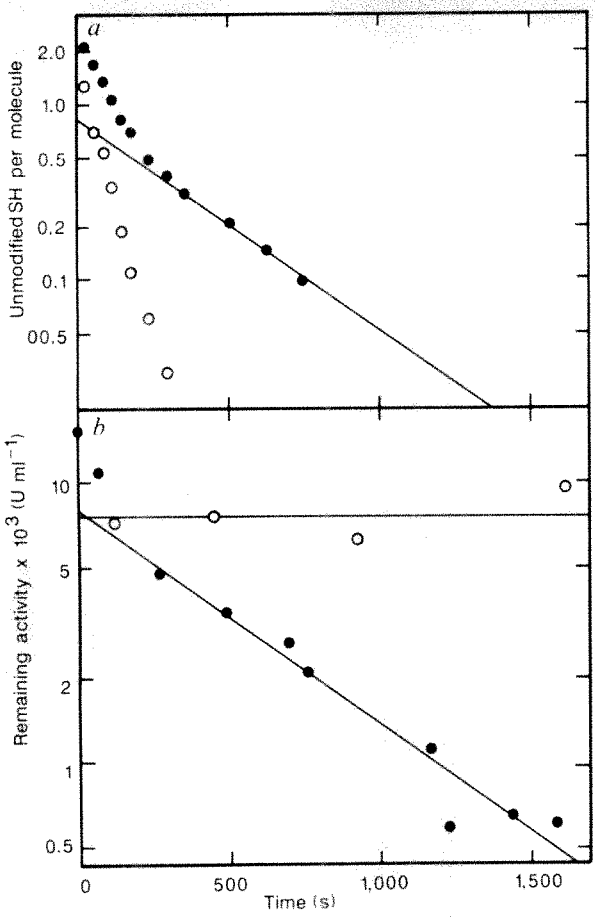

Fig. 3 Covalent modification of PPIase sulphydryls with *p*(hydroxymercuri)-benzoate in the absence (●) and in the presence (○) of 1.44 μM CsA. *a*, Time course of the modification of accessible thiols in 0.035 M HEPES buffer, *p*H 7.8 at 8.0 °C. PPIase (1.9 μM) was incubated with 28 μM *p*HMB and the extent of the modification reaction was followed by the increase in absorbance at 249 nm (with $\Delta\varepsilon_{249} = 7{,}000\ M^{-1}\ cm^{-1}$)[18]. A very fast modification reaction occurred within the deadtime of mixing, which reduced the concentration of *p*HMB to 16.1 μM. This burst may originate from the presence of rapidly reacting SH groups on the protein, but it probably results mainly from the presence of residual dithiothreitol in the enzyme solution. The slow part of the modification reaction was biphasic in the absence of CsA (●); 1.95 ± 0.2 SH groups per molecule reacted with $k_1 = 1.5 \times 10^{-2}\ s^{-1}$ and 0.8 ± 0.3 SH groups per molecule reacted with $k_2 = 2.8 \times 10^{-3}\ s^{-1}$. In the presence of CsA (○), 1.89 ± 0.2 SH groups per molecule were modified with a rate constant of $k = 1.55 \times 10^{-2}\ s^{-1}$. The slow phase was absent. *b*, Loss of catalytic activity of PPIase (1.9 μM) in the course of the reaction with *p*HMB in the absence (●) ($k = 2.0 \times 10^{-3}\ s^{-1}$) and in the presence (○) of 58.7 μM CsA. PPIase activity towards the test peptide was measured after a 1,200-fold dilution into the assay mixture. This high dilution was selected to decrease the concentrations of PPIase and of CsA below the K_i-value.

structure[7,10,11] suggest a fundamental role in cellular metabolism. Both CsA-binding and prolyl isomerase activity involve binding to a peptide chain and this activity could, therefore mediate binding to polypeptide chains in the cell, for example in the course of, or after, protein biosynthesis. Such a role would, however, be at variance with the proposed role of CsA in the regulation of gene transcription[16]. More extensive conclusions about the cellular function of PPIase/cyclophilin are not warranted because at present it is not known whether it is the actual target of CsA during immunosuppression and whether it is important for slow steps in the *in vivo* protein folding process.

Aminoacylation of RNA minihelices with alanine

Christopher Francklyn & Paul Schimmel

Department of Biology, Massachusetts Institute of Technology, Cambridge, Massachusetts 02139, USA

The genetic code is determined by both the specificity of the triplet anticodon of tRNAs for codons in mRNAs and the specificity with which tRNAs are charged with amino acids. The latter depends on interactions between tRNAs and their charging enzymes, and an advance in understanding such interactions was provided recently by the demonstration that a major determinant of the identity of alanine tRNA is located in the amino-acid acceptor helix. Multiple substitutions in many distinct parts of the molecule do not prevent aminoacylation with alanine[1]. Substitution of the G3·U70 base pair with G3·C70 or A3·U70 in the acceptor helix prevents aminoacylation *in vivo* and *in vitro*, however[1], and the introduction of this base pair into $tRNA^{Cys}$ (ref. 1) or $tRNA^{Ph}$ (refs 1, 2) enables both to accept alanine. The importance of a single base pair in the acceptor helix and the results of recent footprinting experiments[3] prompted us to investigate the possibility that a minihelix, composed only of the amino-acid acceptor-TΨC helix, could be a substrate for alanine tRNA synthetase. We show here that a synthetic hairpin minihelix can be enzymatically aminoacylated with alanine. Alanine incorporation requires a single G·U base pair, and occurs in helices that otherwise differ significantly in sequence. Aminoacylation can be achieved with only seven base pairs in the helix.

Figure 1*a* shows the sequence and cloverleaf structure of $tRNA^{Ala/GGC}$, with the amino-acid acceptor-TΨC helix and loop indicated by shading. In the three-dimensional structure of tRNA, the four arms of the cloverleaf are combined into two helical segments which are approximately at right angles, forming an L-shaped structure. The amino-acid acceptor and TΨC sequences form one continuous helix that terminates at the 3′ end in four unpaired bases of the sequence $XCCA_{OH}$. In addition to the G3·U70 base pair, this structural motif of $tRNA^{A}$ has intrachain base pairing and stacking interactions, which promote stability. A significant amount of the synthetase-tRNA interaction is concentrated in the acceptor-TΨC helix, as indicated by the large block of contiguous phosphodiester bonds that are protected from nuclease digestion by the bound synthetase (Fig. 1*a*).

The resulting hairpin $minihelix^{Ala}$ (Fig. 1*b*) was synthesized using the template-primer system shown in Fig. 1*c*, and comprises twelve base pairs with a seven-nucleotide loop. The

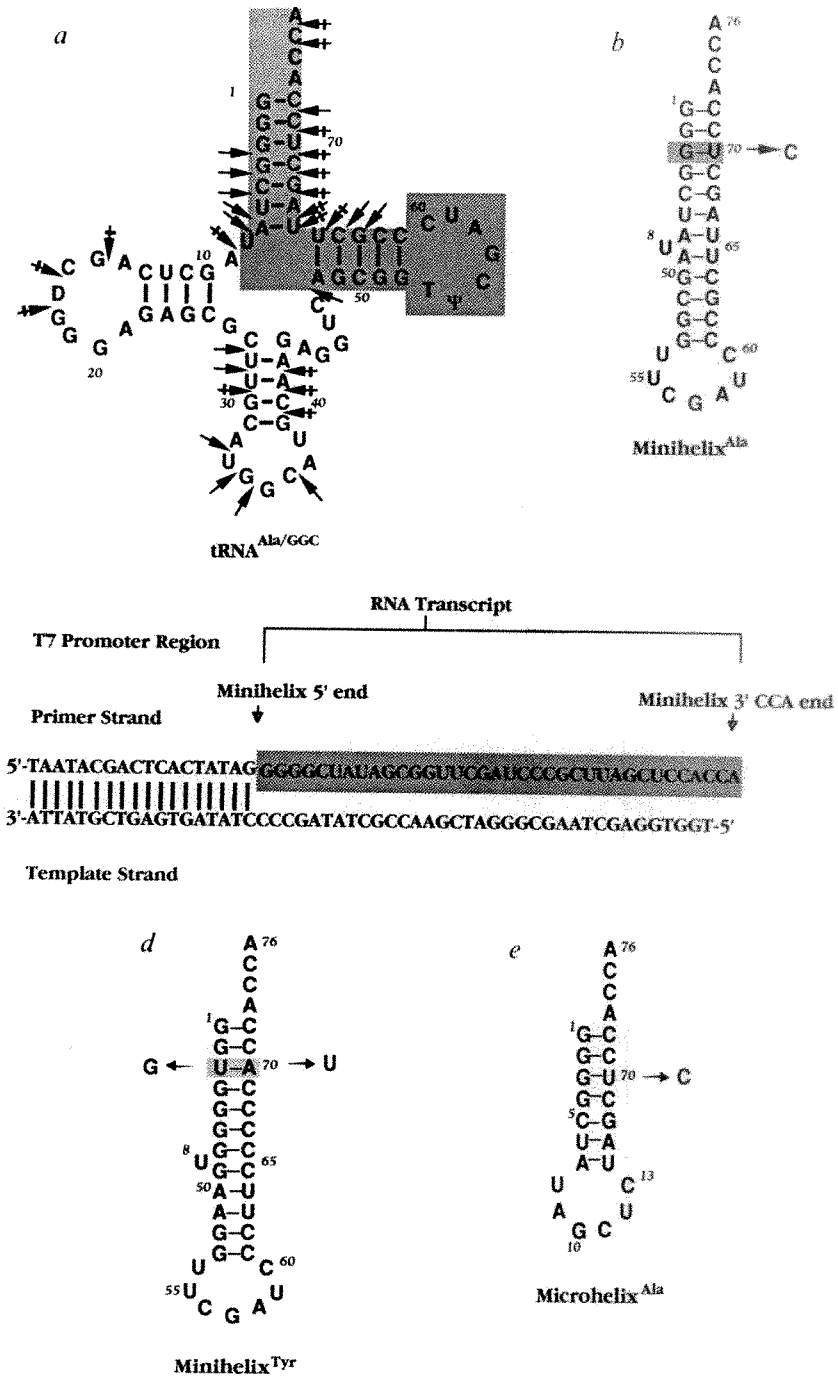

Fig. 1 *a*, Sequence and cloverleaf structure of $tRNA^{Ala/GGC}$ with nucleotides used in the construction of the minihelix indicated by shading. Phosphodiester bonds on $tRNA^{Ala/UGC}$ that have been probed by nucleases in the presence and absence of bound alanine tRNA synthetase are also shown (arrows)[3]. Those which are protected from nuclease attack are shown by cross-hatched arrows. *b*, Synthetic hairpin minihelix based on the acceptor-TΨC helix of $tRNA^{Ala/GGC}$. A variant of this helix substituted C70 for U70. Numbering is based upon that for intact $tRNA^{Ala}$. *c*, Template-primer system for the synthesis of minihelices and microhelices. The sequence of $minihelix^{Ala}$ is shown as an example. For the synthesis of other helices, a different DNA template strand was hybridized to the common 17-base pair T7 promoter strand. *d*, A synthetic minihelix based upon the acceptor-TΨC helix and loop of $tRNA^{Tyr}$. A second helix with a G3·U70 base pair was also made, as indicated. *e*, A synthetic microhelix based upon the acceptor helix of $tRNA^{Ala}$, with a loop comprised of nucleotides from U8 to C13.

Methods. The RNA minihelices and microhelices were synthesized in transcription reactions[22,23] using T7 RNA polymerase and a synthetic DNA template featuring a double-stranded promoter region and a long 5′ overhang corresponding to the transcribed sequence. T7 RNA polymerase was either purchased commercially (U.S. Biochemicals) or purified according to Grodberg and Dunn[24]. Transcription reactions were incubated for four hours at 37 °C in a buffer containing 40 mM Tris-HCl (*p*H 8.1), 5 mM dithiothreitol, 1 mM spermidine, 50 $\mu g\ ml^{-1}$ bovine serum albumin, 80 $mg\ ml^{-1}$ polyethylene glycol (relative molecular mass, M_r, of 8,000), 20 mM $MgCl_2$, 4 mM of each nucleotide, and 2.5 U μl^{-1} of T7 RNA polymerase. The DNA concentration in each strand was 0.25 μM. The reactions were terminated by phenol/chloroform extraction and then precipitated with ethanol. The full-length transcript was isolated by preparative gel electrophoresis from denaturing 20% polyacrylamide gels followed by electroelution or diffusion. The concentration of RNA in the preparations was determined by the absorbance at 260 nm at *p*H 7.5, 23 °C. A hyperchromicity value of 1.43 was used to correct the absorbance determinations. (This was obtained by measuring the absorbance of an RNA sample digested to completion with RNase T2 relative to an unhydrolysed sample.) For substrates that charged with alanine, the concentrations determined in this way (corrected when necessary for the minor fraction of molecules that terminated at their 3′-ends in C[25,26]), agreed with the concentrations determined by calculating the alanine acceptance.

uridine at position 8 was included in the acceptor-TΨC structure because this nucleotide is conserved in all prokaryotic and cytoplasmic tRNAs[4], is protected on one side by the bound enzyme (Fig. 1*a*), and is easily integrated into the acceptor-TΨC unit. We do not explore here whether this nucleotide is essential. Three additional minihelices were synthesized to test whether base substitutions in the acceptor stem exert the same effect on amino-acid acceptance that has been reported for the full-length RNA^{Ala} (ref. 1). A derivative of $minihelix^{Ala}$ was constructed in which U70 was replaced by C70 (Fig. 1*b*). This substitution has been shown to eliminate the aminoacylation function of RNA^{Ala} (ref. 1). A minihelix that corresponds in sequence to that of the acceptor-TΨC helix of $tRNA^{Tyr}$ was synthesized as well as a G3·U70 variant of that minihelix (Fig. 1*d*). The sequence of the acceptor-TΨC stem of $tRNA^{Tyr}$ differs from that of $tRNA^{Ala}$ at seven of 12 base pairs, providing a system in which to test whether G3·U70 retains its strong influence on alanine identity in a different sequence context. In addition to these four minihelices, a fifth helix (the 'microhelix') was synthesized. This consisted of the seven base pairs of the acceptor helix of $tRNA^{Ala}$, connected by a six base-pair loop (Fig. 1*e*). In the sequence of $microhelix^{Ala}$, the sequence of the loop starts at U8 and continues into the 5′ side of the D-stem, such that C13 is joined to U66. A G3·C70 variant of this sequence has also been constructed.

Aminoacylation of preparations of $minihelix^{Ala}$ was examined at pH 7.5 and 37 °C. As a negative control, wild-type $tRNA^{Tyr}$ was used as a substrate. At a concentration of 4.5 μM, the minihelix is aminoacylated at catalytic concentrations (15 nM) of alanine tRNA synthetase, whereas there is no detectable aminoacylation of the control under the same conditions (Fig. 2*a*). At higher concentrations of the enzyme (300 nM), near-complete aminoacylation of the minihelix is observed within 20 min (Fig. 2*a*, inset).

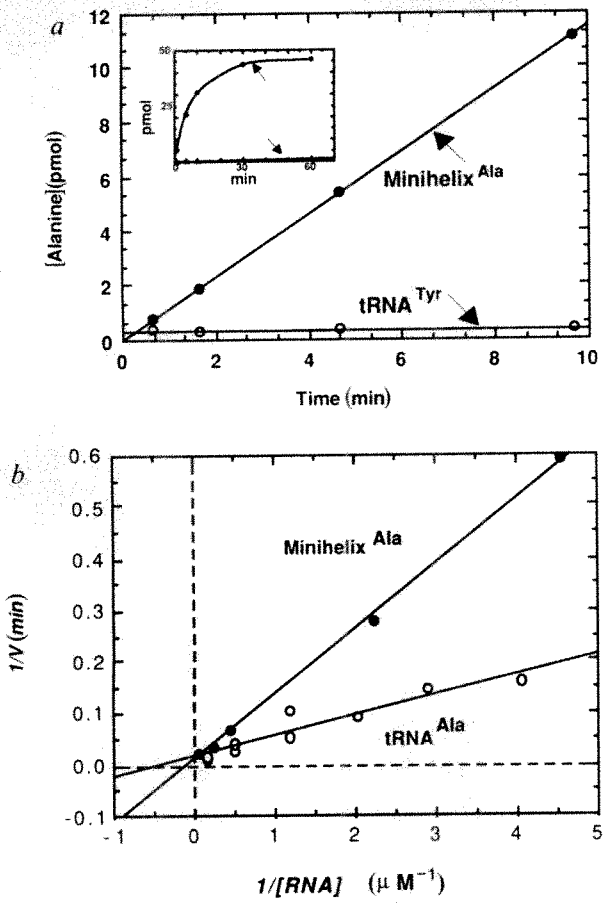

Fig. 2 *a*, Aminoacylation of $tRNA^{Tyr}$ and of $minihelix^{Ala}$. The assays were carried out at *p*H 7.5, 37 °C, as previously described[20,21] in a buffer containing 50 mM sodium phosphate (*p*H 7.5), 100 μg ml^{-1} bovine serum albumin, 20 mM potassium chloride, 10 mM $MgCl_2$, 20 mM β-mercaptoethanol, 4 mM ATP, 20 μM alanine, 2.4 μM [2,3-^{3}H] alanine and 4.5 μM $minihelix^{Ala}$ RNA or 5 μM $tRNA^{Tyr}$. The reactions were initiated by adding purified alanine tRNA synthetase to a final concentration of 15 nM. The inset shows an experiment that compares the aminoacylation of 2.5 μM $minihelix^{Ala}$ with 5 μM $tRNA^{Tyr}$ at an alanine tRNA synthetase concentration of 300 nM. *b*, Plot of inverse velocity against inverse RNA concentration for the aminoacylation of $tRNA^{Ala}$ and $minihelix^{Ala}$. Each point was obtained from the determination of the initial linear rate of aminoacylation at varying substrate concentrations of either the minihelix (over a ten-min interval) or of $tRNA^{Ala}$ (over a 2.5-min interval). The concentration of purified alanine-tRNA synthetase was 15 nM. The reaction conditions were otherwise similar to those in Fig. 2*a*.

A determination of the initial rates of aminoacylation at several substrate concentrations allowed the individual kinetic parameters, the Michaelis constant K_m, and k_{cat} to be determined separately for two substrates. Figure 2*b* shows a plot of inverse velocity against inverse RNA concentration. The plots for both $tRNA^{Ala}$ and $minihelix^{Ala}$ extrapolate to nearly the same intercept on the ordinate, indicating that the enzyme has a similar maximal velocity for the two substrates. The K_m parameter is about fivefold higher for the minihelix, however, suggesting that it binds less efficiently to the enzyme (Table 1). This factor of five corresponds to about one kcal mol^{-1}, which is sufficiently small to be accounted for by one or two van der Waals' contacts that may be absent in the enzyme-minihelix complex, as compared to the analogous complex with wild-type $tRNA^{Ala}$. Because k_{cat} and K_m are close to values observed for the native tRNA, the fragment must possess the structures required for both binding and passage through the transition state.

Table 1 Kinetic parameters for the aminoacylation of $tRNA^{Ala}$ and of helical fragments with *Escherichia coli* alanine tRNA synthetase

Substrate	K_m (μM)	k_{cat} (s^{-1})	k_{cat}/K_m (M^{-1} s^{-1})
$tRNA^{Ala}$	2.0	0.89	4.4×10^5
$Minihelix^{Ala}$	11.4	1.5	1.3×10^5
G3·U70 $minihelix^{Tyr}$	8.8	0.48	5.3×10^4
$Microhelix^{Ala}$	35.9	0.28	7.7×10^3

Aminoacylation reactions were carried out as described in the Fig. 2 legend. The concentration ranges of each of the substrates used to measure the kinetic parameters were as follows: $tRNA^{Ala}$, 0.25–6.4 μM; $minihelix^{Ala}$ and G3·U70 $minihelix^{Tyr}$, 0.22–25 μM; and $microhelix^{Ala}$, 0.5–25 μM. Purified alanine tRNA synthetase was used at a concentration of 15 nM (as determined by active site titration[19,20]) for all kinetic assays. The parameters for all of the RNA substrates were determined at a saturating ATP concentration (4 mM) but at a subsaturating concentration (20 μM) of alanine. The high K_m of alanine tRNA synthetase for alanine (0.25 μM[20]) required prohibitively high radioactive alanine concentrations to achieve saturation. In earlier work, it has been shown that the K_m for $tRNA^{Ala}$ shows little sensitivity to the concentration of alanine[21].

The G3·C70 variant of $minihelix^{Ala}$ was synthesized and found to be completely inactive for aminoacylation with alanine, even under conditions where a relatively high (20-fold higher than that used for the kinetic parameter determination) enzyme to substrate ratio was used (Fig. 3*a*). This suggests that the G3·U70 base pair is also important in determining the amino-acid identity of the minihelix, as it does in the intact $tRNA^{Ala}$ (ref. 1).

A 'tyrosine' minihelix was also synthesized (Fig. 1*d*) and tested for aminoacylation with alanine. As in the case of $minihelix^{Ala}$, the presence of G3·U70 is required for efficient aminoacylation. The rate of aminoacylation of the G3·U70 variant of $minihelix^{Tyr}$ is only 2.5-fold slower than that of the $minihelix^{Ala}$. This result indicates that alanine tRNA synthetase does not exert significant catalytic discrimination against the six base pairs that are not common to $minihelix^{Ala}$ and G3·U70 $minihelix^{Tyr}$. On the basis of a determination of the kinetic parameters for G3·U70 $minihelix^{Tyr}$, the rate reduction can be largely attributed to the k_{cat} parameter (Table 1).

The amino-acid acceptor portion of $tRNA^{Ala}$ comprises only seven base pairs. We observed that a 'microhelix' based on just the sequence of the $tRNA^{Ala}$ acceptor stem can be completely aminoacylated by the enzyme, at a reduced rate relative to that of $minihelix^{Ala}$ (Fig. 3*b*). The kinetic parameters for $microhelix^{Ala}$ were determined under the same conditions as for the minihelices (Table 1). The K_m for $microhelix^{Ala}$ is 18-fold higher and the k_{cat} is threefold lower than the respective parameters for $tRNA^{Ala}$. The differences between the values for $microhelix^{Ala}$ and $minihelix^{Ala}$ demonstrate the effect of the removal of sequences corresponding to the TΨC stem and loop. The greater effect on K_m suggests that, in the progressive deletion of sequences outside the acceptor stem, some contacts with the enzyme have been lost. On the basis of the relative Michaelis constants (K_m) for $tRNA^{Ala}$ and $microhelix^{Ala}$, the decrease in binding energy is about 1.7 kcal mol^{-1}. The lost contacts do not seem to be crucial to catalysis however, because the effect on k_{cat} is relatively small. Other experiments showed that efficient aminoacylation of the microhelix requires the G3·U70 base pair (data not shown).

Although the influence of the G3·U70 base pair on the K_m parameter is important in discriminating $tRNA^{Ala}$ from other tRNAs, there is evidence that the k_{cat} parameter is more important[5]. For certain tRNAs, some or all of the sequences which determine identity are located in the anticodon[6–10]. The data in Table 1 show that for $microhelix^{Ala}$, the k_{cat} parameter is within a factor of three of that for wild-type $tRNA^{Ala}$. Thus, once bound

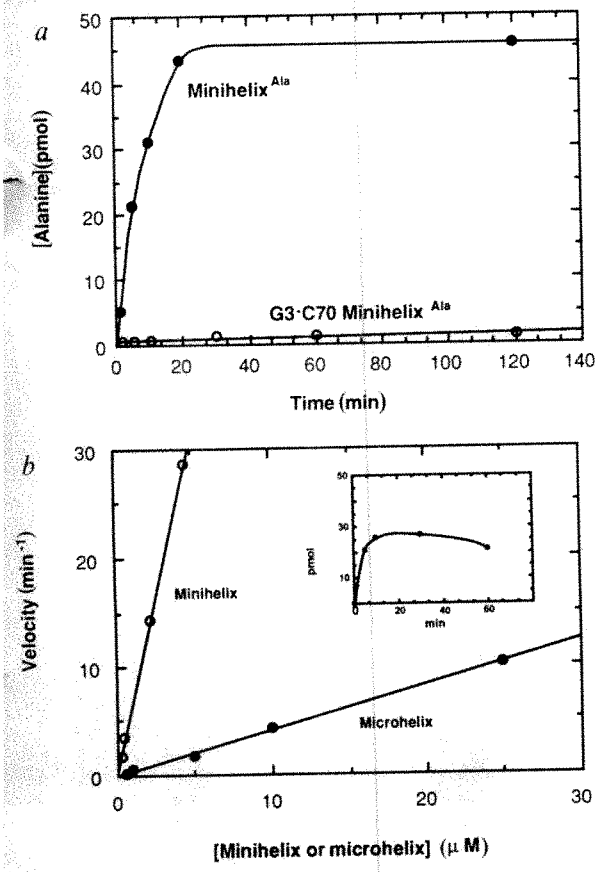

Fig. 3 *a*, Initial rate of aminoacylation with alanine of the 'wild-type' and G3·C70 variant of minihelix^{Ala}. The RNA substrates were present at a concentration of 5 μM, and alanine tRNA synthetase was added to a final concentration of 300 nM, which is a twentyfold increase over the concentrations used in the determination of kinetic parameters. *b*, Initial velocity of aminoacylation with alanine against the concentration of mini- and microhelix^{Ala}. The concentrations of the RNA substrates were as follows: minihelix^{Ala}, 0.25–4.5 μM; microhelix^{Ala}, 0.5–25 μM. Alanine tRNA synthetase was added to a final concentration of 15 nM, and the reaction conditions were similar to those in Fig. 2. The inset shows an aminoacylation experiment where the concentration of microhelix^{Ala} was 3 μM and the concentration of alanine tRNA synthetase was 1 μM.

to the enzyme, the microhelix is aminoacylated at a comparable rate to that of intact, native tRNA^{Ala}.

Although we have confirmed that G3·U70 acts as a positive determinant for recognition by alanine tRNA synthetase, we cannot rule out the possibility that tRNA^{Ala} possesses negative determinants that reduce its interactions with non-cognate synthetases. These negative determinants may, in part, lie outside the acceptor-TΨC helix.

Earlier studies suggested that partial tRNA molecules or tRNA fragment combinations might be substrates for aminoacylation *in vitro*, although the overall yields of aminoacylation were 5% or less in some cases[11,12]. There are examples of naturally-occurring tRNAs that are truncated versions of the typical four-armed cloverleaf pattern, although they are not as reduced in size as the molecules studied here. In the sequence analyses of several mammalian mitochondrial genomes, a tRNA$^{Ser/AGY}$ has been identified that has an ordered structure in which the D-stem and loop are absent[13,14]. Also, at least one other enzyme involved in tRNA metabolism (RNase P) is able to use RNA substrates that are smaller than a complete tRNA[15].

It has been speculated that, during an early stage of evolution, small tRNA molecules were esterified with amino acids in a system that was a precursor to protein synthesis (see summary in ref. 16). These molecules could have had sequences that influenced the selection of the amino acid attached by the primordial synthetase[17]. The data presented here show that, for one amino acid at least, information sufficient for its specific attachment to an RNA molecule can be encoded by sequences proximal to the 3′-amino-acid attachment site.

It has been speculated that primitive RNA genome molecules were tagged by tRNA-like structures in early evolution[18]. These tags might have been used by a primordial enzyme as replication initiation points. In the light of these suggestions, our results invite speculation that these tags could have been short RNA minihelices, which after serving as primitive RNA telomeres, were released to become pre-tRNAs upon which the first peptides were synthesized.

We thank F. William Studier for the strain which overexpresses the T7 polymerase, Kelvin Hill for assistance in the kinetic determinations, and Helen Edwards for helpful comments on the manuscript. This work was supported by grants from the NIH.

Long-range structural changes in proteinase K triggered by calcium ion removal

Jürgen Bajorath, Srinivasan Raghunathan, Winfried Hinrichs & Wolfram Saenger

Institut für Kristallographie, Freie Universität Berlin, Takustrasse 6, D-1000 Berlin 33, FRG

The X-ray crystal structure of the subtilisin-type enzyme proteinase K at 1.5 Å resolution[1] shows that is has two binding sites for Ca^{2+}. Scatchard analysis[2] indicates that one Ca^{2+} binds tightly, with pK 7.6×10^{-8} M^{-1}, and the other only weakly. Although Ca^{2+} is not directly involved in the catalytic mechanism and is 16.6 Å away from the α-carbon atoms of the catalytic triad Asp 39–His 69–Ser 224, the activity of proteinase K towards the synthetic substrate succinyl-Ala-Ala-Ala-*p*-nitroanilide drops slowly to ~20% of its original value when it is depleted of Ca^{2+}. This is not due to autolysis of the enzyme[2]. The X-ray crystal structure of Ca^{2+}-free proteinase K shows that removal of Ca^{2+} from the tight binding site triggers a concerted domino-like movement of five peripheral loops and of two α-helices. At a distance of 25 Å from this

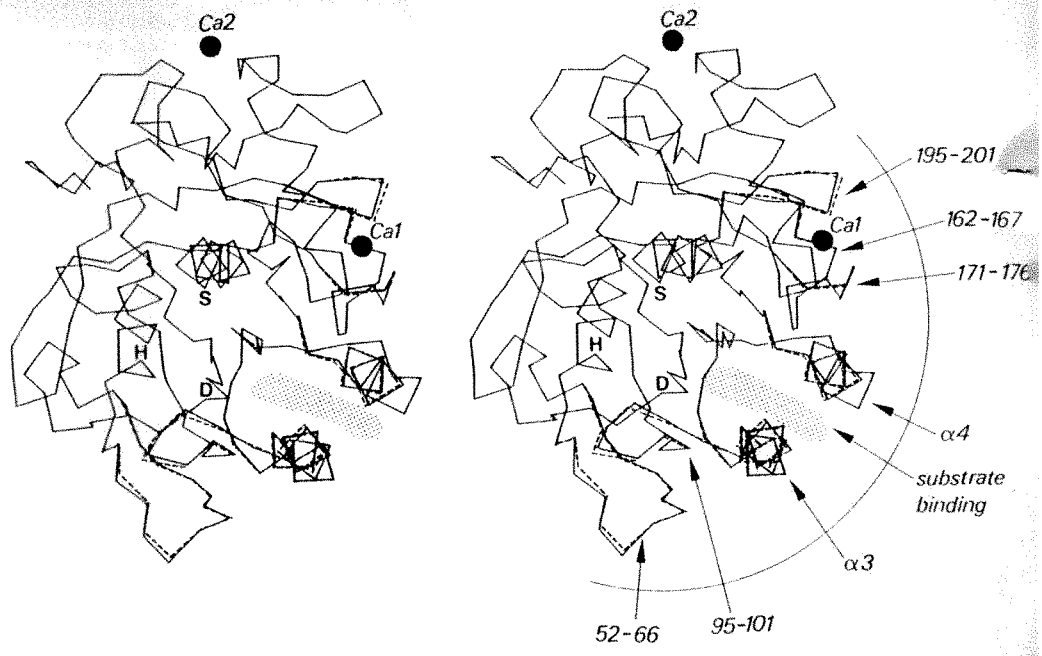

Fig. 1 Stereo view of C_α-superposition of Ca^{2+}-containing and Ca^{2+}-free proteinase K molecules. The least-squares fit procedure for the whole molecule gives an r.m.s. deviation of 0.22 Å. If only the 'isomorphous' atoms that are in identical positions within ~0.1 Å are included, the r.m.s. deviation is 0.04 Å. Sections where differences in atomic coordinates exceed 0.2 Å have an r.m.s. deviation of 0.74 Å and are shown in broken lines for Ca^{2+}-free proteinase K. The Ca^{2+}-binding sites Ca1 and Ca2, the substrate-binding site and the segments that move after removal of Ca^{2+} are indicated. Significant autolysis of Ca^{2+}-free proteinase K occurs only 48 h after incubation[1]; crystals were obtained after 12 to 24 h.

Methods. Proteinase K (Merck, Darmstadt) was dissolved to 10% concentration in 50 mM Tris-HCl, *p*H 7.8, 280 mM Na-EDTA. Vapour diffusion against 0.8 M $NaNO_3$ yielded crystals isomorphous with the native Ca^{2+}-containing enzyme, of space group $P4_32_12$, $a = b = 68.3$ Å, $c = 108.4$ Å. Film data to 2.18 Å resolution were collected on an Arndt-Wonacott camera (Elliott GX20 generator, CuK_α graphite monochromator); there were 11,634 independent reflections ($R_{merge,sym,I} = 5.2\%$) with 85% $>1\sigma_F$. Phasing was with a 1.5 Å 'native' model[1]; manual model building was based on $2F_o - F_c$ and 'omit' maps (FRODO[12]; Evans and Sutherland, PS 300), followed by restrained least squares refinement cycles[13]. *R*-factor is 18.1% for all data $>3\sigma_F$; model consists of C, N, O and S atoms and 94 water oxygens with $B < 30$ Å. Drawn with the program in ref. 14.

calcium-binding site, the geometry of both the secondary substrate binding site and of the catalytic triad is affected by this movement thereby reducing the activity of the enzyme.

The enzyme activity of proteinase K from the mould *Tritirachium album* Limber is so high that it will even digest keratin[3,4]; it is a calcium-dependent enzyme. The catalytic triad Asp 39-His 69-Ser 224 and the two strands of the substrate-binding region corresponding to residues 100–102 and 132–135, form an antiparallel triple β-sheet structure with the substrate, and have been characterized by crystal structure analysis of proteinase K bound to two different peptide chloromethane inhibitors[5,6]. The more strongly binding of the two Ca^{2+}-binding sites (Ca1) is well defined and coordinates in the form of a pentagonal bipyramid: if the two side-chain carboxyl oxygen atoms of Asp 200 are taken as one ligand, then the Pro 175 C=O and Asp 200 $O_{\delta1}O_{\delta2}$ are in apical positions, with Val 177 C=O and four water molecules occupying the equator. In contrast, the coordination sphere of the weaker binding site (Ca2) is incompletely defined in the X-ray structure, by Thr 16 C=O, Asp 260 $O_{\delta1}O_{\delta2}$ and two water molecules[1].

If these Ca^{2+} ions are removed using EDTA and subsequent gel filtration, the enzyme activity of proteinase K decreases by ~80%, falling with $t_{\frac{1}{2}} \sim 3$ h. Activity can be restored to only 28% by excess Ca^{2+} (ref. 2). This behaviour is not associated with autolysis of the enzyme, which becomes significant only after 48 h incubation[2], so we interpret it as resulting from structural changes induced when proteinase K is depleted of Ca^{2+}. We therefore undertook an X-ray crystallographic study of the Ca^{2+}-free enzyme; methods are given in the legend to Fig. 1.

Figure 1 shows that there are no cuts in the polypeptide chain and that the main portion of the molecular structure of proteinase K, including the weaker binding site Ca2, is only marginally affected by removal of Ca^{2+} if at all. Significant structural changes giving shifts greater than 0.2 Å in atomic coordinates occur in a coherent peripheral section. These are indicative of a concerted motion triggered by the substitution of $Ca^{2+} \cdot 4H_2O$ by two water molecules at the Ca1 binding site (Fig. 2); this motion propagates in a domino-like way through adjacent segments of the molecule. These segments involve the two peripheral α-helices, α3 and α4, and the five loops comprising residues 195–201, 162–167, 171–176, 95–101 and 52–66, which make contact through van der Waals interactions, hydrogen bonds and a salt bridge (Table 1). These subtle local changes in molecular structure are associated with more severe positional shifts, deletions and additions of water molecules in the first hydration sphere, suggesting that alterations in the peripheral tertiary hydrogen bonding are substantial. The motion is bounded in an anticlockwise sense (Fig. 1) by a loose connection between loop 195–201 and the protein carboxyl terminus, which acts as buffer, and in 'clockwise sense' by loop 52–66 which is 30 Å away from Ca1 and is exposed to solvent. The movement of the tyrosine residues in loop 52–66 was also detected by circular dichroism[2], suggesting that these structural changes that occur on removal of Ca^{2+} are an intrinsic property of the molecule, and not a result of crystal lattice effects.

The secondary substrate binding site is formed by two strands, from residues 100–102 and 132–135. The latter is linked with site Ca1 through the loop of amino acids 171–176. The shift expected after Ca^{2+} removal (accompanied by isomerization of *cis* Pro 171 to the *trans* form) with concomitant reduction in enzymatic activity[2], does not occur; probably because loop 171–176 is tightly anchored on to helix α6 by a disulphide bond from Cys 178–Cys 249 (Fig. 2a and b). Instead, the peptide carbonyl group of Gly 100, which is part of loop 95–101 and 25 Å away from Ca1, is shifted by ~0.8 Å, so that hydrogen bonding to the substrate is diminished or even impeded (Fig. 2*c*). Side chains of catalytic triad sequence Asp 39–His 69–Ser 224 are rotated somewhat. Consequently, the hydrogen bond between Ser 224 O_γ and $N_{\varepsilon2}$ His 69, which is necessary for the catalytic proton transfer, is lengthened from 3.01 Å in the 'native' Ca^{2+}-bound enzyme to 3.54 Å in the Ca^{2+}-free state (Fig. 2*d*).

The shifts in atomic positions at the catalytic centre can explain the reduction in enzymatic activity of proteinase K on removal of Ca^{2+}. That the activity is not lost completely is

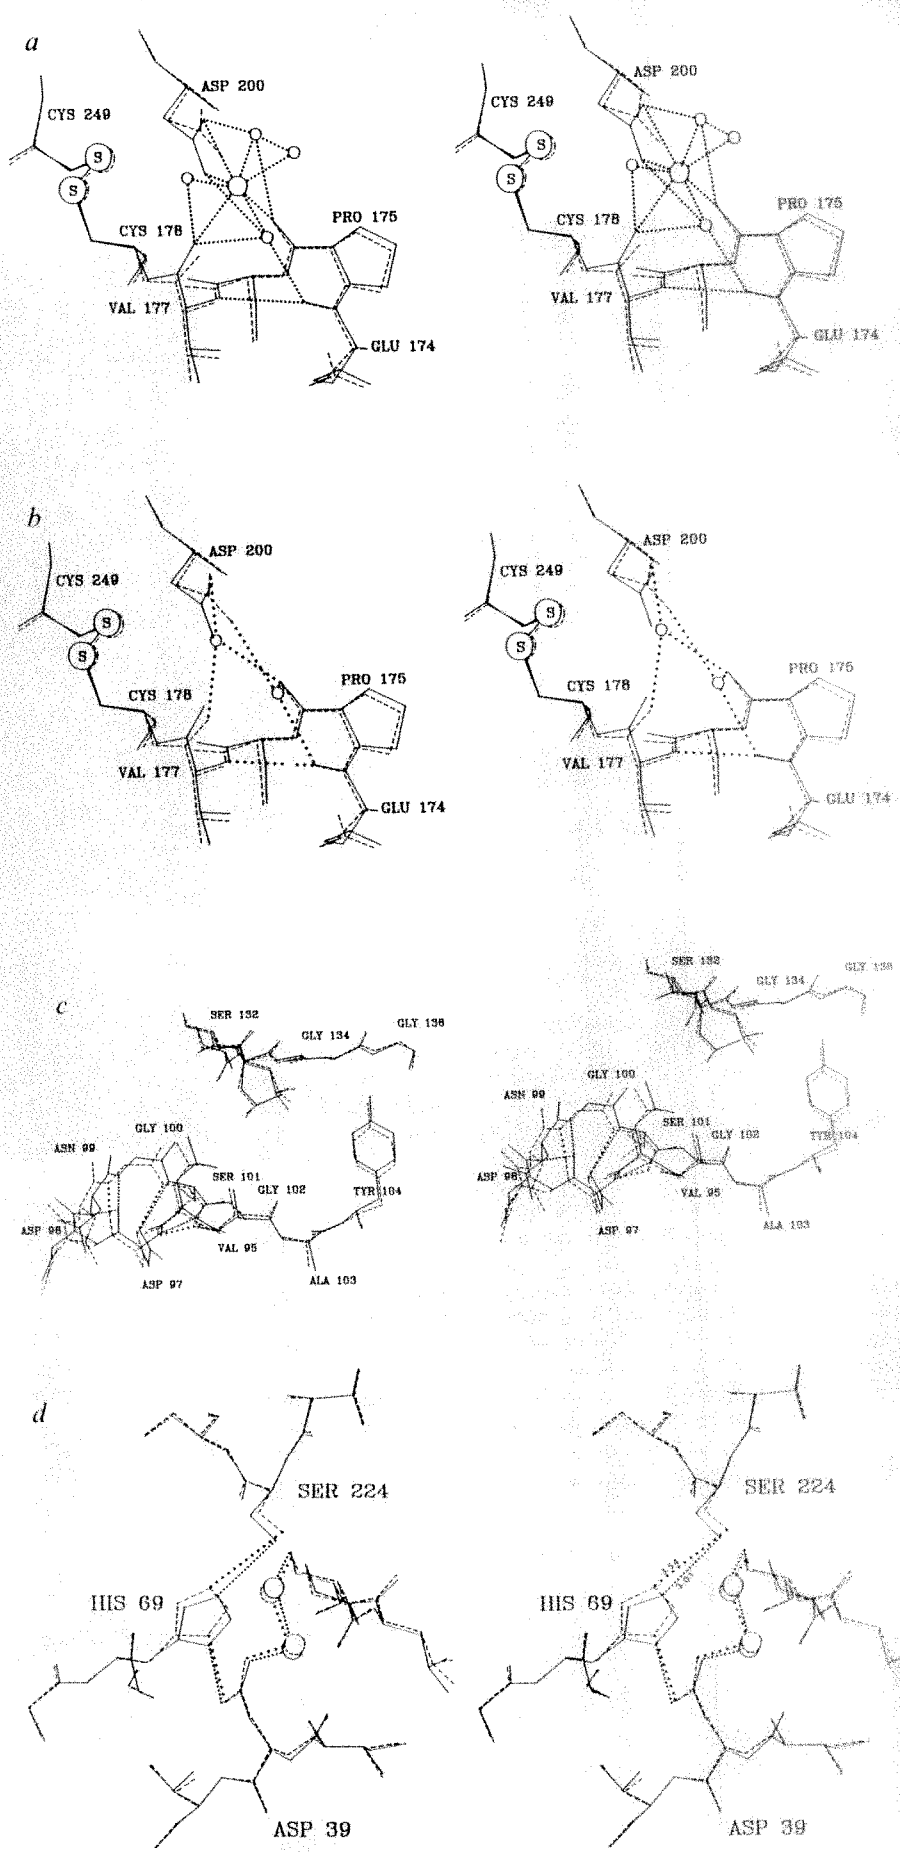

Fig. 2 *a–d*, Stereo views of different sections of the molecular structure of 'native' proteinase K containing Ca^{2+} (solid lines) and of Ca^{2+}-free proteinase K (broken lines). Hydrogen bonds and Ca^{2+} coordination bonds are indicated by dotted lines, the smaller dots referring to Ca^{2+}-containing proteinase K and larger dots to Ca^{2+}-free proteinase K. Drawn with the program from ref. 14. *a*, *b*, The Ca^{2+}-binding site Ca1 drawn with (*a*) and without (*b*) Ca^{2+}. Coordination and hydrogen bonds indicated by dotted lines, small spheres are water molecules, the larger sphere is Ca^{2+}. The disulphide bond is marked S; Cys 249 is attached to helix α6. The secondary substrate-binding site (segment 130–134) that does not shift significantly when Ca^{2+} is removed is at the lower left (not shown). *c*, The secondary substrate-binding site. The structure of segment 132–135 is almost unaffected by removal of Ca^{2+}, whereas the segment 100–102 changes position and conformation. The hydrogen bonds with Asp 97 (dotted lines) are all lengthened in the Ca^{2+}-free enzyme by 0.3–0.5 Å. *d*, View of the catalytic site. Main-chain atoms are almost unaffected, but side chains shift so that the length of the critical hydrogen bond between Ser 224 O_γ and $N_{\varepsilon 2}$ His 69 increases by 0.53 Å when Ca^{2+} is removed. Water molecules are drawn as spheres.

Table 1 Intramolecular interactions between segments which move domino-like when Ca^{2+} is removed from proteinase K

Segment*	Interactions
195–201	Ala 164 C=O···Tyr 195 N
	Ala 166 N···Tyr 196 C=O
162–167	Asp 165 O_δ···W326···Ser 197 O_γ
	Asp 200 C ($O_{\delta1}$···W283; $O_{\delta2}$···W282) ⊖ — Val 177 C=O; Glu 174 C=O; Pro 175 C=O
171–176	
	Asn 142 $N_{\delta1}$···Ser 173 C=O
	Ala 146 C=O···W317···Ser 176 C=O
142–154 (α4)	Asp 112 C ($O_{\delta1}$···$N_{\eta1}$; $O_{\delta2}$···$N_{\eta2}$) ⊖ ⊕ C Arg 147
95–101	Met 111≡(Ala 144, Leu 148)
and α3	(Trp 91, Val 95, Leu 96)≡(Tyr 59, Tyr 60, Tyr 61)
	Asp 98 C=O···$N_{\delta2}$; $O_{\delta1}$···His 69 N; C
52–66	(active site)
	Asn 67

Dashed lines represent hydrogen bonds X—H···A, with 2.68 Å ≤ X···A ≤ 3.20 Å; triple lines represent hydrophobic interactions. The two peripheral α-helices involved in the movement are α3 (residues 103 to 121) and α4 (residues 142 to 154).

*See Fig. 1.

probably due to the relatively subtle nature of the structural changes. The slow rate of this reduction in activity can be explained by the tightly bound Ca^{2+} at site Ca1 resisting chelation by EDTA, together with the associated movements in the hydration sphere which probably dampen this process even further. The altered hydration of Ca^{2+}-free proteinase K could trap the enzyme in a new energy minimum (calculations to be published). This would explain why the activity of proteinase K is not fully recovered after addition of excess Ca^{2+} (ref. 2).

Proteinase K does not autolyse after removal of Ca^{2+} for 48 hours (ref. 2), probably because the disulphide bridge Cys 178–Cys 249 stabilizes the geometry of the 'empty' Ca1 binding site, thereby preventing even partial unfolding. Two related subtilisins, BPN and Novo, also have two Ca^{2+} binding sites, but in different positions[7–11], and they do not contain disulphide bridges. This could explain why they unfold after depletion of Ca^{2+} and become sensitive to enzyme attack to autolyse readily.

The authors thank the Deutsche Forschungsgemeinschaft and the Fonds der Chemischen Industrie for support. S.R. acknowledges the Alexander von Humboldt Foundation for a fellowship.

Advances in two-dimensional electrophoresis

S.M. Hanash and J.R. Strahler

New developments in the first dimension step of two-dimensional electrophoresis have expanded the utility of the technique in cell and molecular biology.

WHILE two-dimensional electrophoresis is unsurpassed by any other technique for simultaneously resolving hundreds of polypeptides, its potential to contribute to our understanding of molecular processes remains largely untapped. Because of the difficulty in achieving adequate reproducibility and truly high resolution, the technique has successfully been practised in a relatively small number of laboratories. Those difficulties notwithstanding, it was evident at a two-dimensional electrophoresis meeting held in Vienna last November* that the technique has been used to identify a good number of novel proteins that play a role in cell activation, proliferation, differentiation and other functions[1]. Genes corresponding to proteins detected on two-dimensional gels have been cloned by several groups, including our own.

Immobilized pH gradients

A major contributor to the variability seen in two-dimensional gel patterns within and between laboratories is the carrier ampholyte (CA) which is the determinant of the first dimension separation, based on charge. Detailed comparisons of patterns generated for the same cell material in separate laboratories have been difficult, hampering efforts to establish collective protein databases of two-dimensional gel information. Problems with CA-based separations include: gaps in the gel patterns, resulting from discontinuities in the pH gradient, which varies between sources of CA; drift in the focusing pattern during electrophoresis (particularly severe for basic polypeptides); and difficulty in producing pre-cast gels suitable for two-dimensional electrophoresis.

These difficulties prompted us to develop a two-dimensional approach that utilizes immobilized pH gradients (IPG) for the first dimension separation[2,3]. With IPG, the pH gradient is an integral part of the polyacrylamide gel matrix[4]. The technique overcomes many of the problems encountered when using carrier ampholytes. The pH separation range can be defined from broad to extremely narrow, basic polypeptides can be resolved well, and precast gels can be used. IPG gels can also be loaded with preparative amounts of protein suitable for polypeptide sequencing, because they have higher loading capacities than CA gels.

In the IPG method, gradient slab gels of 0.5 mm in thickness are first cast on a GelBond PAG film in a large format (24 cm wide with a 17-cm pH gradient separation distance). For most applications, the gradient spans three pH units: 4–7 for acidic and neutral polypeptides, and 6.5–9.5 for neutral and basic molecules. Each slab gel yields roughly seventy 3.5-mm-wide first dimension strips. Following extensive washing with deionized water, the gels are dried and wrapped in thin plastic film, and can be stored at −20 °C for several months.

Prior to the second dimension electrophoresis step, the desired number of strips are cut and rehydrated, as a group, with a solution of urea, non-ionic detergent, dithioerythritol and dilute acetic acid. The strips are then placed on the cooling plate of a humidified, sealed electrofocusing apparatus, and sample applicators of between 40 and 80 µl in capacity are placed directly onto the surface of the gel.

The degree of sample entry into the gel is critical. We have found that the best results are obtained using dilute samples with a low salt concentration to which carrier ampholytes have been added, with

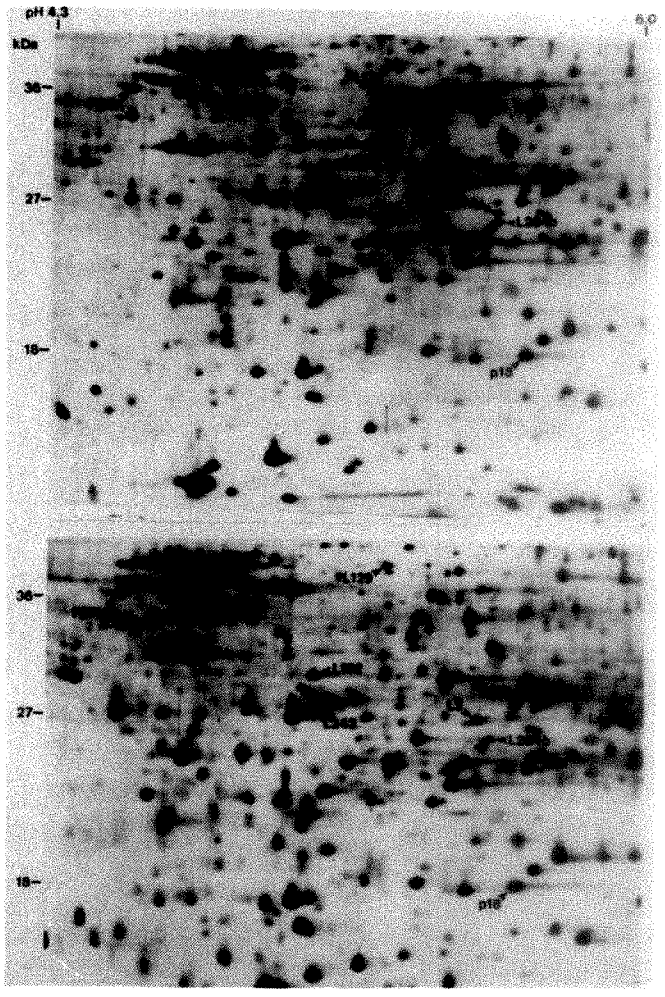

Fig. 1 Comparison of the polypeptide patterns of two separate Epstein–Barr virus-transformed lymphoblastoid cell lines, generated with two-dimensional gel electrophoresis using immobilized pH gradient gels prepared from separate castings. Arrows point to polypeptides of interest to the study of acute leukaemia, some of which have been sequenced and their corresponding genes cloned[6,7]. Some of the differences between the protein patterns are due to genetic polymorphisms, and others to stage of differentiation[7,8].

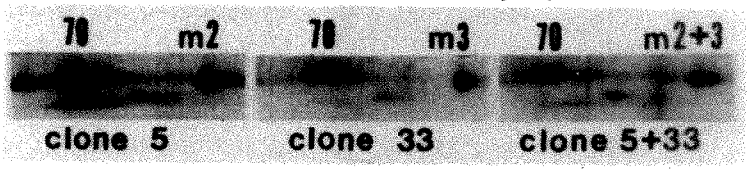

Fig. 2 Close-up sections of two-dimensional gels prepared with narrow immobilized pH gradients (pH 6.3–6.8) in the first dimension. Two mutants of polypeptide 70 prepared from separate mutagenized lymphoblastoid cell lines phenotypically identical in broad-range CA-based gels are clearly resolved by immobilized pH gradients. The mutants differ in charge by <0.003 pH units.

* The International 2-Dimensional Electrophoresis Meeting, Vienna, Austria, 8–11 November 1988.

a low voltage gradient across the gel (30 V cm^{-1}) for the first hour. The voltage can then be increased to 5,000 V (0.1 mA per strip, maximum) for 22–24 hours.

The second dimension electrophoresis step can be performed using vertical or horizontal slab gels. Figure 1 illustrates the reproducibility and resolution which can be achieved using relatively broad pH gradients. An example of the resolution which can be achieved using narrow gradients is shown in Fig. 2.

Other developments

It should be emphasized that in practice, no one technique can lead to the simultaneous visualization of all cellular polypeptides. Thus, for some applications, the selective analysis of protein subsets of interest (such as the low-abundance soluble nuclear proteins) by prior cell fractionation is advantageous.

Additional approaches include the use of separation modes other than isoelectric focusing for the first dimension separation. The direct coupling of microbore HPLC to SDS electrophoresis is particularly promising. In such a system, various HPLC separation modes, from reversed phase to ion exchange, could be used to perform the first dimension separation. In a previous study of plasma proteins, we observed that the resolving power of ion exchange HPLC is equivalent to isoelectric focusing with CA, based on the separation of transferrin variants[5].

Another promising development is the use of capillary electrophoresis as the first dimension separation mode. An effort is also being made to overcome some of the problems experienced with CA-based separations to eliminate gaps in the gels and to allow the production of precast focusing gels containing urea which can be stored for lengths of time.

It is becoming clear that, after an initial lag behind DNA technology, most of the practical knowledge is now in place to allow a major leap forward in our understanding of the organization, structure and function of the principal cellular components which mediate cell function, namely, the proteins. □

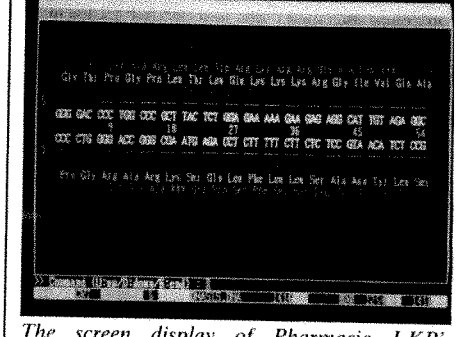
Of peptides and DNA

Neurobiology and neurochemistry will be the talk of the town in Miami ne week during the Miami Bio/Technology *Winter Symposium. Besides an arr of patch-clamps and recorders, the exhibits will feature products for studyir peptides, and the nucleotides which code for them.*

MEDICAL Systems Corporation has a new **micropump system** for controlling the ejection of fluids from micropipettes in neurobiotechnological studies *(Reader Service No. 101)*. The company's Neuro-

Medical Systems' micropump for neurobiology.



Phore BH-2 has both a pneumatic and an ionophoretic pump module, and can deliver intracellular or extracellular ejections of minute volumes using up to five pumps in parallel. The ejection schedule for each pump can be programmed independently. Medical Systems Corporation also offers multibarrel micropipettes for use with the NeuroPhore BH-2 system to enable researchers to eject several different fluid combinations for investigating cell responses. The company is exhibiting in booth 78.

United States Biochemical, exhibiting in booths 62 and 63, offers a range of **neuropeptides** which affect the central nervous system *(Reader Service No. 102)*. The company is noteworthy for producing Bombesin and MBHA-peptide resin, the preferred resin for producing alpha-carboxamide peptides, but they also sell endorphins, delta sleep-inducing peptide, alpha- melanocyte stimulating hormone, and enkephalins. Purified amino acids and derivatives for peptide synthesis can also be chosen from USB's product listing, which contains over 6,000 products. The company has recently been appointed by Perkin- Elmer Cetus as a co-distributor of Perkin-Elmer Cetus's GeneAmp reagents for performing the polymerase chain reaction.

Software smarts

Beckman has updated its popular MicroGenie **sequence analysis software** to include the capability to calculate circular restriction maps, including double and multiple digests *(Reader Service No. 103)*. The new feature allows the user to enter and store lists of restriction enzymes and their recognition sites, even before analysis, and to calculate restriction fragment sizes based on gel mobilities. The new version retains the old MicroGenie's shotgun DNA sequencing function, whe sequences can be merged and scanned f overlaps, insertions, deletions and mi matches, and the homology search ar alignment function, which draws upon th GenBank nucleic acid database and th National Biomedical Research Found tion protein sequence database. Wit MicroGenie, it is also possible to predi protein secondary structures and prob bilities, determine residue and codo frequency, predict and plot protein hydr phobicity, and find inverted repe regions and calculate the free energ Beckman offers a free demonstration dis for MicroGenie, which runs on IBM compatible computers. The company i exhibiting in booths 29 and 30.

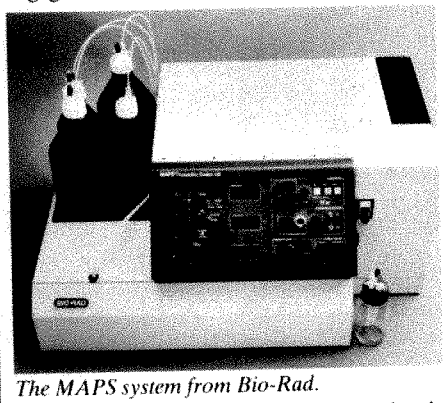
Pharmacia LKB, exhibiting in booth 88 and 89, has just launched its PROSI **protein analysis software** package fo personal computers *(Reader Service No 104)*. The software can perform secondar structure predictions, based upon th Chou-Fasman and Robson theories; cal culate the maximum amino acid homolog

The screen display of Pharmacia LKB's DNASIS.

between two sequences; perform molecular weight and homology searches; plot homologies; and perform hydrophobicity analyses. PROSIS has keyword search and database access functions, and can be used with an optional CD-ROM disk that contains both the GenBank and National Biomedical Research Foundation databases. Version 3.0 of Pharmacia-LKB's DNASIS DNA analysis software has also recently been released. DNASIS has been updated to perform homology searches in one-third of the time required by previous versions, and to incorporate improved colour graphics. The new version also allows the automatic entry of fragment migration distances from an optional sonic digitizer for the creation of restriction

maps in either circular or linear formats.

IntelliGenetics last year released version 3.0 of its KeyBank data bank of **protein and nucleic acid sequence patterns** for use with the company's suite of software for mainframe computers *(Reader Service No. 105)*. KeyBank consists of over 1,200 functional and structural sequence patterns — referred to as "keys" — derived from protein and nucleic acid sequences published in the scientific literature. IntelliGenetics says KeyBank gives researchers a more efficient way to examine the burgeoning nucleic acid and protein sequence databases. KeyBank contains 16 categories of protein keys, including amino acid modifications, signal sites, binding sites, and enzyme and allosteric sites, and 112 categories of nucleic acid keys, including DNA structure, regulatory regions, binding sites, repeats and ends. IntelliGenetics will have information on KeyBank in booth 27.



DelPhi is the name of a soon-to-be-released software package from Biosym for calculating the **electrostatic potential** of macromolecules *(Reader Service No. 106)*. *DelPhi* enables users to examine the effects of charge distribution, ionic strength, and dielectric constant on the electrostatic potential of a macromolecule without resorting to dielectric models or including explicit solvent. There is no limit on the number of atoms, residues or molecules that can be treated. Biosym says the software yields results that agree within five per cent with analytic solutions for simple spherical models. The output electrostatic potential grids may be viewed as 3-dimensional contour maps using Biosym's *Insight* modelling software. *DelPhi* also generates a dielectric map identifying points inside and outside a molecule's solvent- accessible surface, and a list of potentials at selected coordinates and total electrostatic energy. Biosym is in booth 87.

Pure protein (and DNA)

J.T. Baker, in booth 69, has a new **non-porous polymeric matrix** named Natrix for the purification and concentration of DNA and RNA *(Reader Service No. 107)*. Separation with Natrix is achieved by the selective binding of the nucleic acid to the phase in an ion-pairing buffer. The minimum capacity of the matrix is 50 μg of nucleic acid for 200 mg of Natrix. The nucleic acids are eluted using 60 per cent acetonitrile. Baker says Natrix allows the recovery of normal nucleic acids in quantitative amounts, without impairing their capacity for ligation. According to the company, Natrix can be used to purify ten samples of DNA from a caesium chloride gradient in less than 30 minutes. Natrix is available in prepacked Bakerbond columns or as a bulk sorbent.

Boehringer Mannheim Biochemicals, in booths 81-83, has introduced Resorufin-labelled casein, a non-specific substrate for detecting a wide variety of **proteases** that contaminate various protein preparations *(Reader Service No. 108)*. The company says the new substrate is both reliable and sensitive in the determination of protease activity: each lot is tested with sequencing-grade trypsin, and as little as 0.1 μg trypsin can produce an absorbance difference of 0.07 at 574 nm in 15 minutes at 37 °C.

Bio-Rad recommends its MAPS preparative system for the **process-scale purification of protein** *(Reader Service No. 109)*. Bio-Rad says the MAPS can be used in its integral sanitation method for purifying grams of monoclonal antibodies and

The MAPS system from Bio-Rad.

other proteins per day in a completely sanitized environment. The MAPS system can be treated with 1 M sodium hydroxide, and has an IBM-compatible computer for system control, data collection and manipulation, methods development, and automated sample injection. Compatible column chemistries include Bio-Rad's Affi-Prep protein A columns for MAb's, HRLC MA7 ion-exchange columns for high-molecular weight proteins, macroporous ABCM cation exchange columns for concentration from tissue culture media, and Affi-Prep polymyxin supports for removal of endotoxins. Bio-Rad is exhibiting in booth 3.

Cloning and sequencing

Promega, in booth 54, offers its TaqTrack sequencing system — based on the thermostable DNA polymerase from *Thermus aquaticus* — for sequencing applications *(Reader Service No. 110)*. Promega says as a sequencing enzyme, *Taq* exhibits consistent band intensity, low background, and a high degree of accuracy. Because *Taq* works at 70-95 °C, the TaqTrack system decreases the secondary structure of DNA templates, permitting polymerization through highly structured regions. The system is optimized to produce readable sequence data from 1 to 500 bases with a single-stranded DNA template. A deaza nucleotide mix which substitutes 7-deaza dGTP for GTP is available for resolving band compressions associated with GC-rich templates.

BRL has two **cDNA cloning systems** for cloning double- stranded cDNA into the bacteriophage vectors λgt10 and λgt11 in as little as three days *(Reader Service No. 111)*. Based on *Eco*R1 linker addition, both cloning systems guide the researcher through all of the cDNA cloning steps: methylating internal *Eco*R1 sites, repairing DNA termini, phosphorylating linkers, ligating linkers to DNA, digesting linkers, removing linkers by chromatography, and ligating DNA to the vector. Each step is outlined in the manual, which also includes troubleshooting instructions. The systems include positive control DNA to monitor the success of each step which makes phage with insert DNA form blue plaques and phage containing linkers remain colourless. Each system contains reagents for performing five reactions, with 0.5–2.5 μg cDNA per reaction. BRL is in booths 76 and 77.

The Base Runner **multi-gel electrophoresis sequencer** from International Biotechnologies, Inc. accommodates the independent running of two 32-lane gels simultaneously *(Reader Service No. 112)*. The Base Runner holds two 20.3 cm-wide gels of either 30, 45 or 60 cm in length. It has a lockable base which can be rotated 360°, and a buffer tank clamping system that IBI says eliminates user error and plate breakage while reducing setup time. The spring-loaded clamp allows users to slide tanks into place: releasing the clamp causes the tank's silicon gasket to compress against the glass plate, forming a leakproof seal. The Base Runner's gel sandwich is composed of a specially treated notched glass plate and a glass plate coated with a thermoconductive material that IBI says prevents "smiling". IBI is exhibiting in booth 43. □

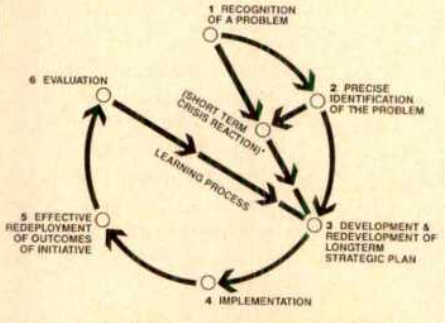
Turning the switch on skills

Richard Pearson

Industrial concerns may have to rethink their in-house training programmes — or pay dearly for the skilled workers they need.

WITH the dramatic downturn in the numbers of school-leavers available to enter the labour market and higher education systems of most Western countries, (*Nature* **355**, 100; 1988), attention is turning to the existing workforce: after all, 70 per cent of those who will be in employment at the end of the century are already in the workforce.

In response to the growing shortage of technical staff, a number of companies are now embarking on special initiatives to retrain non-technical staff and are widening their recruitment net to embrace new types of trainees by setting up conversion courses. Others are introducing special career streams for technical staff to improve their long-term career prospects, and hence retention rates (*Switching on Skills*, NEDD, 1989).



An example of one of these initiatives can be found at the BBC (British Broadcasting Corporation) which has a continuing need to recruit engineering staff to maintain its broadcasting and transmission activities. In the early 1980s the corporation started experiencing increasing difficulty, along with most other employers, in attracting sufficient engineering graduates and school-leavers qualified in mathematics and physics to enter its training schemes. It foresaw these difficulties worsening, and so decided to widen and adapt its graduate training scheme to include arts graduates. When the places were advertised there was a massive response with 8,000 enquiries, and 3,000 applications for the 24 places. An 'O'-level in maths at grade B, or better, was deemed to be the minimum technical knowledge needed and special training tests were used to aid the selection process.

In this way candidates were assessed in near normal training conditions to evaluate their suitability and probable success in the longer term. A special programme was developed to give the trainees the basics of physics in a three-week module. They then followed the 'A'-level trainee programme, both streams eventually merging with the engineering graduate group. The initial off-the-job part of the programme lasts about 13 weeks, and is followed by an 18-month period embracing both off- and on-the-job training.

Although still in its early stages, the programme has been deemed a success, with none of the trainees failing. The BBC has found a completely new source of recruits, reducing their need to compete in the market for experienced engineers. It is argued that as overall salary levels do not have to match the top of the market, the training costs involved, which exceed £10,000 per trainee for the initial 13 weeks alone, are justified.

Another approach to widening the recruitment net and using non-technical recruits has been undertaken by part of the electronics group Plessey. A shortage of real-time programmers was the spur here, and the company looked to retain internal staff. An in-house 26-week course was designed which could not only take students from a wider range of backgrounds than the external equivalent but was also 60 per cent cheaper. It includes foundation elements of maths and electronics as well as the basics of software. This is followed by short modules on specialist high-level languages and project work. Staff and ex-students have described it as compressing two years of university study into six months.

Initially the course was aimed at graduates but more recently a base entry standard of good 'O'-levels was accepted

The best of training programmes could fail if it is not adapted in the light of experience.

for staff who might otherwise have been in danger of redundancy elsewhere in the company. The course was externally validated and in the second year the Manpower Services Commission, a government agency, arranged to buy places to retain graduates and to help ease the more general skill shortages. Selection was by aptitude test and interview with a notional target age range of 20–30 years, reflecting the perceived market prejudice against older workers. All 90 of the students taking part so far have successfully completed the course; the benefits of 'growing your own' having been emphasized by high retention rates. For the externally sponsored students, normally graduates with no information technology experience and from backgrounds ranging from civil engineering to the arts having been in employment for up to 5 years, the course were seen to be highly practical. Their relatively short duration, when compared with a 12-month MSc, means that students can find financial support more easily. By allowing externally sponsored students to participate, the company has been able to continue with the course even in times of slack internal demand.

At Barr and Stroud, manufacturers of electro-optical systems, the concern was to provide career routes for specialist staff and improve retention by allowing career progression outside the traditional management hierarchy. The company has introduced a number of new programmes including a career structure with three streams for professional, specialist and managerial staff, explicit grade and progression criteria, an integrated and visible salary structure, and an appraisal system. The latter is a critical means of identifying training needs and succession planning. The programme, which is currently being implemented, will, it is hoped, result in clearer and better career prospects for staff, leading to lower staff turnover.

For other companies interested in developing such initiatives there are a number of lessons of value from these and the complementary case studies (presented in *Switching on Skills*). The first is the need is to recognize the nature and durability of the problem, such as recruitment difficulties, high wastage or poor utilization. Often this is done but only leads to short term, or crisis reactions. The real need is to identify the precise problem and develop a strategic response. Implementation of the plan then follows; it is at this stage that many initiatives stop. In many cases, however, staff are retrained and then their new skills are not exploited. The programme needs to be evaluated and the lessons fed back into the design and implementation strategies (see figure). Few programmes are 100 per cent successful the first time, and even where they are the problem or the environment will continue to change. The challenge now is to increase the skills of the existing workforce to complement the new skills provided by the young. □

植物工学・医薬開発分野の経験ある研究者

サッポロビール㈱は「ビールを基軸とした複合経営」を目指し、都市再開発から医薬および農業関係に至る広い分野でR&Dに取り組んでいます。このたび、展開を加速するために全社的な組織改革を行いました。これにともない右記の研究所では戦力増強を計画しています。

募集要項

■植物工学研究所(群馬県新田郡)
●植物の遺伝子工学研究者(チーム・リーダー)……1名
上記分野の研究歴5年以上。年齢40歳位。博士号必要。
微生物遺伝子工学経験者で植物に関心のある方も可。

■医薬開発研究所(静岡県焼津市)
●医薬品合成、薬理、微生物スクリーニングの各主任研究員クラス……各若干名
経験3年以上。年齢30歳前後。

《応募方法》
履歴書(写真貼付)、研究歴要旨および論文別刷を下記にご送付ください。

☞郵送・問合先:〒104 東京都中央区銀座7-10-1 サッポロビール株式会社
研究開発本部(近野/高塩)☎(03)572-6111 Fax(03)572-0221

JAPAN'S OLDEST BRAND SINCE 1876
SAPPORO BEER

(W5807)A

HIGHER SCIENTIFIC OFFICER (BAND I)
(21-month appointment)
TISSUE CULTURE AND CYTOLOGY DEPARTMENT

A plant scientist is required to explore the potential of asymmetric cell fusion in potato improvement. Knowledge of plant tissue culture techniques is required and experience of protoplast manipulation would be an advantage. A technical support worker is also available for this position.

Salary: £10,026–£13,460

Non-contributory superannuation.

Qualifications: First or upper second class honours degree in a related discipline with at least two years' relevant post-graduate research experience which may be a course of research and study leading to a Ph.D. degree.

The Institute is an equal opportunities employer.

Curriculum vitae complete with the names and addresses of three refereees should be sent to **Mr I Paxton, Personnel Officer, by 24 February 1989** quoting the appropriate reference (**Ref. TCC/1/89**).

(8279)A

Universität zu Köln

An der Mathematisch-Naturwissenschaftlichen Fakultät der Universität zu Köln ist zum Sommersemester 1990 am Institut für Entwicklungsphysiologie eine

Professur C3
fur Entwicklungsbiologie

wieder zu besetzen.

Bewerber (innen) sollen sich durch ein aktives Forschungsprogramm auf dem Gebiet der molekularen Grundlagen der Entwicklung des Nervensystems (vorzugsweise von Insekten) qualifiziert haben. Eine Mitarbeit im Sonderforschungsbereich 243 "Molekulare Analyse der Entwicklung zellulärer Systeme" ist möglich. Eine Beteiligung an den Lehrverpflichtungen des Instituts wird erwartet.

Bewerbungen mit Lebenslauf, Schriftenverzeichnis, einschließlich Sonderdrucken der wichtigsten Publikationen und kurzem Forschungsplan werden bis zum 15. April 1989 erbeten an den **Dekan der Mathematisch-Naturwissenschaftlichen Fakultät der Universität zu Köln, Albertus-Magnus-Platz, 5000 Köln 41.**

(W5812)A

BROWN UNIVERSITY

Providence, Rhode Island ● 02912

Division of Biology and Medicine

BROWN UNIVERSITY

PROFESSOR AND CHAIRPERSON, SECTION OF PHARMACOLOGY

The Division of Biology and Medicine plans to appoint a Professor and Chairperson of Pharmacology during the academic year 1989-90. With the construction of a new wing to the Biomedical Center, opportunities exist to develop the current program in biochemical pharmacology into a broadly-based, unit in pharmacological sciences, which interacts with programs in biochemistry, molecular biology, neurobiology, pathology, and clinical pharmacology. The successful applicant is expected to lead this development, to establish a vigorous research program of national distinction, and to take administrative responsibility for pharmacology teaching at Brown. Pharmacology faculty participate in medical, graduate, and undergraduate teaching. The integrated structure of the Division of Biology and Medicine maximizes opportunities for research and teaching interaction among all of the biological and medical sciences, as well as with other disciplines at Brown University. Applicants should submit a curriculum vitae, representative reprints, and the names of three references to **Dean Frank G. Rothman, Division of Biology and Medicine, Brown University, Providence, RI 02912**. The deadline for receipt of these application materials is March 31, 1989. *An Equal Opportunity/Affirmative Action Employer.* (NW3263)A

GRIFFITH UNIVERSITY

Division of Science and Technology

LECTURER

Pharmacology/Physiology
(Continuing Appointment)
Ref. No. F14-88

Applications are invited for a lectureship in the areas of Pharmacology/Physiology in the Division of Science and Technology. The successful applicant will be expected to teach pharmacology at the undergraduate and postgraduate levels and to contribute to physiology teaching at undergraduate levels.

Applicants should possess a suitable higher degree and a record of research in an appropriate area. Some teaching experience would be an advantage.

The appointee will be expected to commence duties from 1 November 1989. It is anticipated that the appointment will be made in the lower half of the lecturer's salary range, i.e. A$30,737-$34,750.

Applications from women and men are encouraged. Employment benefits include parental leave and the possibility of access to full-time child care and after-school care.

Further details may be obtained from the Divisional Administrator, Division of Science and Technology, to whom applications (including curriculum vitae and names and addresses of two referees) should be sent by 31 March 1989.

Griffith University Nathan Qld 4111 AUSTRALIA

AN EQUAL OPPORTUNITY EMPLOYER (W5825)A

THE UNIVERSITY OF CALIFORNIA IRVINE CANCER CENTER

is seeking an assistant adjunct professor of medicine. Cancer research with expertise in molecular and cell biology. Study of transformation of human melanocytes and chemoprevention. Funding for at least 2 years available. Opportunity to develop independent career. Postion available July 1, 1989.

Send letter, list of at least 3 references and curriculum vitae to: **Faculty Recruitment (Laboratory) Frank L. Meyskens, Jr., M.D., Director, UCI Cancer Center, 101 The City Drive, Building 44, Route 81, Orange, CA 92668.** Applications accepted until April 1, 1989 or until position is filled.

UCI is an EOP/AA employer. (NW3190)A

UNIVERSITY OF OXFORD

GLYCOBIOLOGY UNIT

POSTGRADUATE RESEARCH ASSISTANT 1B

BR/283

Applications are invited from suitably qualified graduates for the post of Research Assistant 1B to join an active group studying the structure and function of glycoproteins. The successful candidate will be involved in the characterization of oligosaccharides from diverse sources and in associated support duties. Previous experience is not essential, but an understanding of various chromatographic, radiolabelling and computing techniques would be an advantage.

The appointment offers promising career opportunities in this exciting field, and is available for 3 years in the first instance.

Salary on the scale £8,675-£13,365 p.a.

Applications, including a curriculum vitae and the names and addresses of 2 referees, should be sent to: The Administrator

An Equal Opportunity Employer. (8286)A

The University is an Equal Opportunity Employer

UNIVERSITY OF DURHAM

DEPARTMENT OF CHEMISTRY

LECTURER IN PHYSICAL CHEMISTRY
LECTURER/SENIOR LECTURER/ READER IN POLYMER CHEMISTRY

Applications are invited for two permanent posts from October 1989.

(a) Lecturer in physical chemistry. The successful candidate should have research interests which suitably complement or supplement the strengths of the Department, some of which are (i) solid-state and surface chemistry, (ii) spectroscopy, (iii) molecular interactions, (iv) kinetics and mechanism. Preference may be given to applicants with research interests in polymer materials.

(b) Lecturer/Senior Lecturer/Reader in polymer chemistry. The post is open to candidates with organic, inorganic or physical chemistry backgrounds, but an established research reputation in polymer chemistry is essential.

The initial salaries will be on the appropriate scales according to qualifications and experience, Lecturer A (£9,260–£14,500) or Lecturer B (£15,105–£19,310), Senior Lecturer/Reader (£20,270–£22,910).

Further particulars may be obtained from the **Registrar, Science Laboratories, South Road, Durham, DH1 3LE (Telephone (091) 374 2263)** to whom applications (three copies), including the names of three referees, should be sent not later than *Friday, 17th March, 1989* (quoting ref. C1). (8294)A

POSTDOCTORAL FELLOW

Postdoctoral positions are available in a molecular biology-electrophysiology laboratory for research on the structure-function relationship of brain and cardiac sodium, potassium and calcium channels. Site-directed mutagenesis and hybrid chimeras are used to construct channel mutants for expression in Xenopus oocytes and stably transfected cell lines are being established. Channel technology would be helpful. Interested applicants should send resume and addresses for three letters of reference to:

Rolf H. Joho, Ph.D., Assistant Professor or Arthur M. Brown, M.D., Ph.D., Professor and Chairman, Department of physiology and Molecular Biophysics, Baylor College of Medicine, One Baylor Plaza, Texas Medical Center, Houston, Texas 77030.

We are an equal opportunity employer. (NW3213)A

PUBLIC HEALTH SERVICE
ALCOHOL, DRUG ABUSE AND MENTAL HEALTH ADMINISTRATION
NATIONAL INSTITUTE OF MENTAL HEALTH
NEUROPSYCHOPHARMACOLOGIST

The Neuropsychiatry Branch of the NIMH, under the leadership of Dr. Richard Wyatt, is recruiting for a neuropsychopharmacologist. The individual selected will participate in ongoing basic science studies regarding the CNS effects of a variety of psychoactive drugs, with an initial focus on cocaine, caffeine, and nicotine. These studies will include examinations of the impact of these drugs on neurotransmitter-receptor systems and the design of animal models to assess behavioral effects. Applicants must have a doctoral degree in pharmacology or a related area, and preferably have specific experience in behavioral pharmacology.

Applicants may be accepted as Staff Fellows ($20,000 - 38,000) or Visiting Fellows ($20,000 - $23,000). Staff Fellows must be U.S. citizens with a doctoral degree. Initial appointments are for two years, with further renewals possible. Visiting Fellows may be resident or non-resident aliens with a doctoral degree and no more than three years of relevant postgraduate experience. Visiting Fellows are appointed for one year with possible renewals for two additional years. Interested candidates should send a curriculum vitae, a brief statement regarding experience and research interests, and the names of 3 references to:

(NW3249)

NATIONAL JEWISH CENTER FOR IMMUNOLOGY AND RESPIRATORY MEDICINE

EICOSANOIDS AND PAF RESEARCH

University of Colorado Health Sciences Center

Postcoctoral positions in eicosanoids and platelet activating factor research are currently open in a joint program in the laboratories of the National Jewish Center for Immunology and Respiratory Medicine and University of Colorado Health Science Center in Denver, Colorado. Individuals interested in any of the following projects are encouraged to apply.

'Suicide' Inactivation of Leukotriene A Hydrolase: The objective is to characterize the autoinactivation process that limits formation of the chemotactic agent leukotrianes B_4. The results will facilitate efforts to monitor leukotriene biosynthesis *in vivo* and to comprehend transcellular metabolism of leukotrienes. [See Proc. Natl. Acad. Sci. USA *83*;1349 (1986)]. Contact F.A. Fitzpatrick, 303-270-7494, UCHSC.

Leukotrianes and Platelet Activating Factor: An individual interested in learning and then applying sophisticated techniques of lipid biochemistry, including mass spectrometry, will study the source of arachidonate and involvement of ether phospholipids in eicosanoid and PAF biosynthesis. Experiments will be carried out with inflammatory cells such as mast cells and neutrophils using physiologically relevant stimuli to trigger lipid mediator biosynthesis. [See J. Biol. Chem. *261*;7771 (1986)]. Contact Robert C. Murphy, 303-270-8962, UCHSC.

Platelet Activating Factor in Acute Lung Injury: An individual interested in the mechanisms of lung vascular injury will study hemodynamic effects of PAF and its synergistic interactions with proteases and oxidants and injurious effects of PAF on cultured vascular cells. [See J. Clin. Invest. *79*:1498 (1987)]. Contact N. F. Voelkel, 303-270-8103, UCHSC.

Phospholinase A_2 Involved in Eicosanoid and Platelet Activating Factor Production: The project involves studying the biochemical properties and mechanisms of activation of an arachidonoyl-hydrolyzing phosphalipase A_2 from macrophages. [See Biochem. Biophys. Acts *963*;476 (1988)]. Contact Christina C. Leslie, 303-398-1214, NJCIRM.

Secretion of Lipid Mediators From Cells: The mechanism by which newly synthesized eicosanoids, precursors and PAF are liberated from cells is the objective of these studies. Techniques of cell biology, biochemistry, mass spectrometry, and membrane biophysics will be employed to answer these questions. Contact Peter Henson, 303-398-1380, NJCIRM.

Send or FAX (303-270-7097) letter of interest to the above Professors (UCHSC) or to Prof. P. M. Henson (NJCIRM).

SCRIPPS CLINIC
AND RESEARCH FOUNDATION

RESEARCH INSTITUTE OF SCRIPPS CLINIC
LA JOLLA, CALIFORNIA, U.S.A.

MOLECULAR BIOLOGIST
MEMBRANE BIOCHEMISTRY

A staff position is immediately available for an individual trained in the field of molecular biology with experience in protein chemistry. Studies are already in progress on the molecular mechanisms in leukocyte membranes responsible for transduction of signals initiated by ligand-receptor-G protein interactions. Precise understanding of these events, and experimental manipulation of the system requires the participation of molecular biologists. Considerable scholarly and educational resources are associated with the position. Excellent salary, fringe benefits, grant and technical support are available. Send curriculum vitae, description of research background and research interests, education and training to:

Charles G. Cochrane, M.D.
Department of Immunology, IMM12
Research Institute of Scripps Clinic
10666 North Torrey Pines Road
La Jolla, CA 92037 U.S.A.

Equal Opportunity Employer.

FACULTY POSITIONS
SLOAN-KETTERING INSTITUTE
CELL BIOLOGY AND GENETICS PROGRAM

The Sloan-Kettering Institute invites applications for several tenure-track junior and senior faculty positions in the Cell Biology and Genetics Program. This research program is one of four in the Institute, and is undergoing a major expansion in research at the molecular level on the areas of positive and negative growth control, differentiation, cell structure, intercellular recognition, and morphogenic pattern formation. The Cell Biology Program and the Molecular Biology Program at the Sloan-Kettering Institute are jointly relocating to a new research building which also houses advanced facilities for protein and nucleic acid microchemistry, transgenic mice, and automated mammalian cell micromanipulation. The faculty members of the Cell Biology and Genetics Program are also affiliated as faculty with the Cell Biology Graduate Program at Cornell University Medical School. The positions offered are highly competitive with regard to start-up funds, laboratory space, salary and housing.

Eligible candidates should have a doctoral degree, post-doctoral experience and demonstrate potential and ability to develop an independent, imaginative research program. Formal applications are invited from junior as well as established investigators. Applications should include a curriculum vitae, a list of publications, a summary of research activities and research plan, and the names of three or more references. Applications should be addressed to: **Dr. Joan Massague, Cell Biology and Genetics Program, Sloan-Kettering Institute, 1275 York Avenue, New York, NY 10021.**

(NW3199)A

KING'S COLLEGE LONDON

Biomolecular Sciences Division

POST DOCTORAL POSITION IN PROTEIN CRYSTALLOGRAPHY

Applications are invited for a three year post-doctoral position funded by the MRC, for work on the three dimensional structure of a metallo-β-lactamase enzyme, and its interaction with penicillin and cephalosporin substrates at low temperature. The applicant will also be involved in the structure determination of a penicillin target protein, and its complexes with β-lactam antibiotics.

Salary £11,515-£12,720 including London allowance, according to age and experience. Applications, together with a c.v. and the names of two referees should be sent to **Mr D.M. Drummie, 26-29 Drury Lane, London WC2B 5RL**. Informal inquiries may be directed to Dr B.J. Sutton (01-836 8851), from whom further details may be obtained.

(8284)A

SCOTTISH CROP RESEARCH INSTITUTE
Invergowrie, Dundee DD2 5DA

U.G. 7

HEAD OF CEREAL AND LEGUME GENETICS DEPARTMENT

Applications are invited for the post of Head of the Cereal and Legume Genetics Department of SCRI. The postholder will manage a programme aimed at elucidating the genetic architecture of characters of economic and biological importance in barley and Vicia beans, and at developing genetic improvement strategies. Particular attention is given to the components of yield, disease resistance and malting quality (in barley) and anti-metabolites (in beans). Research includes the use of molecular and biometrical genetics, tissue culture and modelling of physiological and morphological development.

The Department consists of seventeen staff (1 UG7, SSO, 2 HSO, 2 SO, 5 ASO, 5 EW) and is located at Mylnefield, Dundee where excellent laboratory, glasshouse and field facilities are available.

Salary: £16,692–£21,737

Non-contributory superannuation.

Qualifications: Preference will be given to candidates with post-graduate qualifications in genetics and an interest in utilising the most recent technologies of gene manipulation.

The Institute is an equal opportunities employer.

Curriculum vitaes complete with the names and addresses of three referees should be sent to Mr I Paxton, Personnel Officer, by 17 February 1989 quoting the appropriate reference. (Ref. C&LG/1/89) (8281)A

University of Birmingham
School of Basic Medical Sciences

Lecturer in Anatomy

Applications are invited for the above post in the Department of Anatomy which provides the teaching in topographical anatomy, neuroanatomy, histology and cell biology to medical, dental and science students. The successful candidate would be expected to contribute to teaching in one of these areas although particular skills in neurosciences will be welcome.

We are seeking a candidate who can offer evidence of a high level of research achievement and potential probably in cell biology or neuroscience, although candidates with expertise in other areas of interest within the School are encouraged to apply. Expertise in molecular biology, tissue culture, neurochemistry and electrophysiology is available in the School and ample opportunity exists for collaboration.

Salary in the range: £9,260–£19,310 p.a. plus superannuation.

Informal enquiries can be made to **Professor J.J.T. Owen, Department of Anatomy, The Medical School, University of Birmingham, Birmingham B15 2TJ (Phone: 021-414-6812) or to the Head of the School of Basic Medical Sciences, Professor J.H. Coote (Phone: 021-414-6915/6).**

Further particulars and application forms are available from: **The Senior Assistant Registrar, The Medical School, University of Birmingham, Birmingham B15 2TJ (Phone: 021-414-4049)** to whom applications, including c.v. and the names of three referees, should be sent by not later than 24th February 1989.

AN EQUAL OPPORTUNITIES EMPLOYER (8272)A

Position announcement

International distribution

GEOMAR, Research Center for Marine Geosciences which was established in 1987 at the **Christian-Albrechts-Universität in Kiel/ Germany**, invites applications for a BAT/IIa-appointment in

Marine Environmental Geology

BAT/IIa is the classification in the German civil service system equivalent to Research Associate, Senior Researcher or Research Specialist.

The successful candidate will be expected to develop aspects of a research program on the role of fluids in global tectonic and environmental settings as well as participate in the build-up of the Research Center. Desired expertise in one or more of the specialities; chemistry/hydrology of marine pore fluids, trace gases, light isotopes, sensors for dissolved tracers. Applications should be accompanied by an outline of own research interests.

Ph.D. or equivalent degree is required. Women are encouraged to apply.

Please send application, including resumé and addresses of three references, before 1 April 1989 to:

GEOMAR Research Center for Marine Geosciences
Personnel Department
Wischhofstrasse 1-3
D-2300 Kiel 14
Fed. Rep. Germany (W5811)A

POSTDOCTORAL POSITION

A postdoctoral position is available for hormonal and biochemical investigations on male sterility in plants. Candidates should have a Ph.D. in Botany/Plant Sciences with a strong background in plant development and biochemistry. Experience in plant tissue culture, protein and/or hormonal analysis would be desirable. The position is initially for one year with a possibility of renewal for the second year.

Interested candidates should send a CV, reprints/ preprints of papers and at least two letters of recommendation to: **Dr. V. K. Sawhney, Department of Biology, University of Saskatchewan, Saskatoon, SK S7N OWO, Canada.** (NW3261)A

PLANT BREEDING INTERNATIONAL

NEW OPPORTUNITIES WITHIN OUR EXPANDING SCIENCE GROUP

ASSISTANT MANAGERS/RESEARCH ASSISTANT

Two assistant managers and one research assistant are required for two different teams, one working on the molecular biology of plant viruses, and the other on the molecular biology of potato nematode disease resistance. The assistant managers will have line management responsibilities.

Qualifications: Either a HND, BSc or equivalent, and laboratory experience in molecular biology and/or biochemistry, extensive in the case of assistant managers, together with a high degree of care and reliability in experimental work.

For further particulars telephone Cambridge 840411 ext 307, or write to the **Personnel Officer, PBI Cambridge Ltd, Maris Lane, Trumpington, Cambridge CB2 2LQ quoting Ref: SCI/42/43.**

Pharmacia

Pharmacia Genetic Engineering Inc.— Phage —

GENE EXPRESSION — MOLECULAR BIOLOGY

Inflammation/Virology/Autoimmunity

Pharmacia Genetic Engineering Inc. — Phage — went into operation less than 2 years ago and is already poised to play a key role in Pharmacia's quest to offer to its customers, a new generation of tomorrow's health care products. The company comprises a fine team of highly qualified staff (current total, 26 individuals). Phage maintains laboratories at the Torrey Pines Center — in the midst of an environment which exhibits one of the strongest life science growth areas in the United States. We are now expanding our laboratories and are looking for

RESEARCH SCIENTISTS: PHD LEVEL

The qualified applicant must have

- Documented skills in applied molecualr biology (gene cloning, analysis, expression — yeast expression of particular interest), preferably through industrial experience
- Specific expertise in one or several fields, including autoimmunity/cancer/inflammation/virology
- The spirit of a team player
- The desire to become part of a group of achievers

Phage combines the excitement of a start up with the necessary back up by Pharmacia, with its full-fledged R&D, production and marketing organization.

If your interests and expertise meets with our needs, we should get together and tell you more. . . . Please send your CV, including three references for us to contact, to **Pharmacia Genetic Engineering Inc., Attn. Torsten B. Helting, P.O. Box 8827, La Jolla, CA, 92038.** *Confidentiality is guaranteed.*

THE UNIVERSITY OF SHEFFIELD
Department of Human Metabolism and Clinical Biochemistry

POSTDOCTORAL/POSTGRADUATE RESEARCH ASSISTANT

Applicants are invited to apply for this post to join a group studying the behaviour of human bone cells. The position is for one year in the first instance, and the starting salary will be within the IA Range for Research & Analogous Staff £9,865–£15,720 per annum according to age, qualifications and experience.

Applicants should send a full curriculum vitae and the names/addresses of two academic referees to **Dr J A Kanis, Department of Human Metabolism and Clinical Biochemistry, University of Sheffield Medical School, Beech Hill Road, Sheffield S10 2RX** by 20 February 1989. Ref: R862/N.

Informal enquiries may be made to Dr J A Kanis (0742-739176)

An Equal Opportunity Employer (8297)A

UNIVERSITY COLLEGE & MIDDLESEX SCHOOL OF MEDICINE
Department of Pharmacology

RESEARCH TECHNICIAN

Applications are invited for a new three year appointment as a Research Technician (Grade 3: minimum salary £8386 p.a. including London Allowance) to study the receptor-effector mechanisms for substance P and the neurokinins in bladder muscle. The post is supported by Pfizer Central Research and will be under the supervision of Dr. I. Marshall with the collaboration of Mr. E.J.C. Milroy and Mr. C.R. Chapple (Department of Urology, The Middlesex Hospital). Experience or a qualification in Pharmacology or a related discipline would be an advantage. Although based in the Pharmacology Department at UCL, a component of the research could be undertaken at the Pfizer research facilities, Sandwich, Kent.

Applicants should send a curriculum vitae including the names and addresses of two referees as soon as possible to **Dr. I. Marshall, Department of Pharmacology, University College London, Gower Street, London WC1E 6BT.** Equal Opportunities Employer. For further enquiries please telephone: 01-387 7050 ext. 3693. (8301)A

GROUP LEADER POSITION IN MOLECULAR NEUROBIOLOGY

Friedrich Miescher-Institut Basel, Switzerland

The Friedrich Miescher-Institut, a foundation devoted to basic research in cell biology, invites applications for an independent group leader position in neurobiology. Candidates are sought who have an interest in using molecular biology techniques to study the differentiation and the regeneration of the neuronal cell in vitro and in vivo. The candidate should have at least three years postdoctoral experience in molecular aspects of cellular neurobiology. The appointee's group will join two other groups working in the field of neuronal development, led by Dr. Andrew Matus (cytoskeleton) and Dr. Denis Monard (growth factors).

The Institute has strong research programs in cellular and molecular biology and offers an outstanding scientific environment with excellent research facilities. Employment conditions for the offered position are highly competitive. The envisaged starting date is mid-1989 or later. Applications, including an outline of the candidate's proposed research project, should be submitted by February 28, 1989 to **Dr. Denis Monard, Friedrich Miescher-Institut, P.O. Box 2543, CH-4002 BASEL, Switzerland.**

(W5748)A

INSTITUTE OF PLANT SCIENCE RESEARCH
Cambridge Laboratory
Cereal RFLP Mapping Group

The Laboratory is seeking to fill three positions to expand an established and well funded team in the Cereals Research Department, which is constructing detailed genetic maps of the chromosomes of bread wheat and barley using DNA probes to identify RFLP markers. As the maps emerge, genes controlling characters of agronomic significance will be included and thus become 'tagged' for selection by breeders. The three posts will be serviced by two technicians.

The positions are funded for three years by the Agricultural Genetics Company. The technology developed will be licenced to a number of international breeding companies.

Initially the work will be conducted at Trumpington in the Cambridge Laboratory but in early 1990 the group will be relocated together with other staff, to new, purpose built laboratories on the John Innes site at Norwich.

A. Job Ref CR/348
A Higher Scientific Officer with experience in molecular biology and a knowledge of plant genetics is required to undertake a research role in the development of new probes and technology for RFLP analysis and associated techniques as applied to cereal genomes.

B. Job Ref CR/349
Two Scientific Officers are required, to organise and carry out large scale RFLP screening. Some molecular biology training is desirable for both positions. One of the posts will be suitable for a graduate with an interest in the use of computers for data base development.

Salary
Scientific Officer £8,574 pa to £10,994 (£11,477 from 1.8.89)
Higher Scientific Officer £10,026 pa to £13,460 (£13,999 from 1.8.89)
Starting point depending on qualifications and experience.

Qualifications
Higher Scientific Officer. A first or Upper Second class honours degree in a relevant plant science with at least two years post qualifying experience.

Scientific Officer. An honours degree, or equivalent, in a relevant plant science.

Three referees are required for the post of Higher Scientific Officer and two for Scientific Officer.

Applications, quoting the job reference, to the **Secretary, IPSR (Cambridge Laboratory), Maris Lane, Trumpington, Cambridge CB2 2JB, England,** by 27 February 1989.

Further particulars available on request.

The Institute is an Equal Opportunities Employer. (8305)A

SCOTTISH CROP RESEARCH INSTITUTE
Invergowrie, Dundee DD2 5DA

U.G. 7
POTATO BREEDING DEPARTMENT

The Department breeds potato cultivars for the UK ware market and for Mediterranean regions, where it is hoped that new cultivars could create markets for Scottish seed producers, and conducts research into breeding technologies. The breeding of new cultivars may in future become less important than the development of intermediate enhanced germplasm for distribution to commercial breeders.

The appointee will lead a team of 12 and plan and direct the germplasm enhancement work from the choice of parents to the final stages of selection and in addition will design a research programme to complement the breeding work. Integration of research findings, new technologies and refined objectives into the programme will ensure it becoming the fore-runner for breeding in the UK.

Salary: £16,692–£21,737

Non-contributory superannuation.

Qualifications: First or second class Honours degree in plant science, including genetics, and several years' post-graduate experience including a Ph.D. A keen appreciation of recent developments in genetic manipulation and the ability to adapt these to practical applications is essential as are well developed scientific leadership and management qualities.

The Institute is an equal opportunities employer.

Curriculum vitae complete with the names and addresses of three referees should be sent to Mr I Paxton, Personnel Officer, by 17 February 1989, quoting the appropriate reference. (Ref.PBG/1/89) (8278)A

La Trobe University
School of Physical Sciences
RESEARCH ASSOCIATE IN PHYSICS
(Fixed Term three years)

The appointee will work in collaboration with Professor K.D. Cole on theoretical problems in solar-terrestrial physics. The person should have expertise in relevant areas of theoretical physics and be proficient in numerical computing and simulation, have a PhD and evidence of achievement by publication in refereed journals. The appointment is for three years and the person should commence duty on 1 March 1989 or as soon as possible thereafter.

Closing Date: 17 February, 1989. Ref. No: ACA0/627

Salary: $26,617-$30,360

Applications (marked confidential) including reference number, names and addresses of three referees and curriculum vitae should be forwarded to the Staff Officer, La Trobe University, Bundoora, Victoria, Australia, 3083.

Equal Opportunity is University Policy. (W5823)A

UNIVERSITY OF LEICESTER
MOLECULAR RECOGNITION OF INOSITOL PHOSPHATE SECOND MESSENGERS BY INTRACELLULAR RECEPTORS & ENZYMES
TWO POSTDOCTORAL RESEARCH ASSOCIATESHIPS

Applications are invited for two postdoctoral research associateships supported by the SERC Molecular Recognition Initiative to work in collaboration with Dr. B.V.L. Potter (Chemistry) and Professor S.R. Nahorski (Pharmacology) on aspects of the above topic. Leicester University has been recently designated a Centre for Molecular Recognition by SERC and substantial interactive biological and chemical research is already in progress on structure–activity relationships and mechanisms of action of inositol polyphosphate second messengers at receptors regulating intracellular calcium.

One position is for three years and would be suitable for a biochemist/pharmacologist who has an interest and/or record of achievement in receptor mechanisms, the actions of second messengers and enzymology. The other position is for two years and would be suitable for candidates with expertise in organic synthesis and with a significant interest in biological mechanisms. Some of the work will be carried out within the environment of a new joint Chemistry/Pharmacology laboratory at Leicester.

Salary according to age and experience on Scale IA: £9,865 to £15,720 per annum.

Applications with Curriculum Vitae and the names and addresses of two referees should be sent before the end of February to **Dr. B.V.L. Potter (Chemistry, tel: 0533 522129) or Professor S.R. Nahorski (Pharmacology, tel: 0533 522923), University of Leicester, Leicester, LE1 7RH.** (8290)A

THE UNIVERSITY OF TEXAS Southwestern Medical Center AT DALLAS
Department of Biochemistry
POSTDOCTORAL FELLOW POSITIONS BIOCHEMISTRY AND GENETICS OF PROTEIN TRANSPORT

Positions are available to examine the molecular genetics of protein and ribonuclear protein transport across organelle membranes in yeast. Studies will focus on *in vitro* transport methods in conjunction with available genetic and immunological probes to define structure function relationships of the transport apparatus within the nuclear envelope and mitochondrial membranes. Send curriculum vitae or call 214-688-2120, **Dr. Michael G. Douglas, Department of Biochemistry, UT Southwestern Medical Center, 5323 Harry Hines Blvd., Dallas, Texas 75235-9038.** An equal opportunity employer. (NW3221)A

UNIVERSITY OF CAPE TOWN

Dept. of Microbiology:

Lecturer/Senior Lecturer

Applications are invited from Bacteriologists for the above post, with effect from 1 July 1989 or as soon as possible thereafter.

An interest and experience in bacterial physiology and biochemistry, anaerobic bacteriology, microbial genetics and recombinant DNA technology will be a strong recommendation.

The post may be filled on a permanent basis or on a three year fixed-period basis, whereafter it may be renewed or converted to a permanent post.

Applicants should state the level of post for which they are applying and if they wish to be considered for a temporary or permanent appointment. Applicants for the Senior Lectureship should also indicate whether they would be prepared to be considered for a Lectureship.

The salary package includes medical aid, pension and housing subsidy schemes. Details concerning remuneration will be supplied to applicants.

Applications, including a full curriculum vitae, research interests and publications, present salary, and the names and addresses of three referees, should be submitted not later than 24 March 1989 to the Registrar (Attention: Appointments Office Ref. DB), University of Cape Town, Rondebosch 7700, Republic of South Africa, (telex: 5-22208; telefax: 650-2138). Further information may be obtained from the above, or from the Secretary, SA Universities Office, Chichester House, 278 High Holborn, London WCIV 7HE.

The firm policy and practice of the University of Cape Town is to oppose discrimination in any sphere of university life on grounds of gender, race, or creed. UCT has consistently protested, and continues to protest, against apartheid laws and practices and is committed to working towards a just future for our country. Information on this is available on request.

(W5818)A Bates Wells Recruitment CT ● 737R-OS

UNIVERSITY OF DURHAM
PHYSICS DEPARTMENT
EXTRAGALACTIC ASTRONOMY

Applications are invited for a SERC funded Postdoctoral research position tenable for three years starting 1st October, 1989 (or earlier if convenient) to work with Professor R. S. Ellis and colleagues on observational programmes related to the origin and evolution of normal galaxies and the constraints these place in observational cosmology. The department regularly obtains allocations of observing time on SERC telescopes (4.2m WHT, 3.9m AAT and 3.8m UKIRT) and the successful applicant will exploit these facilities, often using instrumentation developed at Durham, in surveys of distant galaxies and quasars, and/or via detailed studies of galaxy populations in various environments at nearby and moderate distances. Salary is on the RA IA scale (£9,865-£15,720) according to qualifications and experience.

Informal enquiries may be made to Professor Ellis (Tel. No. (091) 374 2163).

Further Particulars may be obtained from the **Registrar, Science Laboratories, South Road, Durham, DH1 3LE** (Tel. No. (091) 374 2263) to whom applications (three copies), including the names of three referees, should be sent not later than 28th February, 1989 (quoting ref. P2). (8296)A

UNIVERSITY OF SOUTHAMPTON
DEPARTMENT OF BIOLOGY
LECTURESHIP IN PLANT PATHOLOGY

The University expects to be able to offer a permanent lectureship in plant pathology from October 1989, following the UGC initiative to create opportunities for young staff. Candidates with research experience in molecular/physiological aspects of plant pathology or in the epidemiology of plant diseases would complement the two major research divisions within the department, although other strong research interests will also be considered.

Salary will be assessed on Lecturer Grade A (£9,260-£14,500 p.a.) or B (£15,105-£19,310 p.a.).

Further particulars can be obtained from **Ms J A Doyle, Staffing Department, The University, Southampton, SO9 5NH** to whom applications (7 copies) should be returned by 28th February 1989. Please quote reference 212/JAD. (8292)A

SMITHSONIAN ASTROPHYSICAL OBSERVATORY
Submillimeter Wavelength Telescope Array Positions:
Project Director
Antenna Leader
Software and Imaging Leader
Receiver Scientist

The Smithsonian Astrophysical Observatory announces four positions associated with the design, construction, and operation of an interferometric array of submillimeter wavelength telescopes, currently in the initial stages of its design study.

The array will be a major astronomical instrument, unique in its combination of wavelength coverage (approximately 0.3-2 millimeters) and angular resolution (approximately 0.3-3 arc seconds). It will be mountain-based and is expected to take 2 years to design and 5 years to construct, at a total cost of $30 to $40 million. The Federal government has allocated support for a receiver development laboratory, starting in FY '88, and for a design study, starting in FY '89. Additional funding is being requested.

The **Project Director** will be responsible for the overall scientific technical, and administrative management of the program. The incumbent will coordinate the activities of a team of scientific and technical leaders and an administrative support staff. He/she will establish policy, prepare budget documents, and supervise hiring and other personnel matters. He/she will consult regularly with scientific, technical, and administrative advisors inside and outside the Observatory.

The Project Director must have a Ph.D. and extensive professional experience and knowledge in the techniques and practice of interferometry and/or in millimeter or submillimeter wavelength astronomy. Extensive experience in the management of significant scientific and technical enterprises, as well as excellent qualities of leadership, organization, and communication, are required.

This is a senior level position, with salary depending on qualifications and experience.

The **Antenna Leader** will report to the Project Director and will be responsible for large-scale aspects of the array, including site evaluation, selection, and development; the design, the construction, and performance of individual antennas; antenna configurations and operation as an interferometer. The incumbent will work closely with other project leaders in the scientific, technical, and receiver areas during the design and construction phases, and will have the administrative and technical support needed for this work.

The incumbent should have extensive experience in interferometry, millimeter wavelength astronomy, and/or submillimeter wavelength astronomy, as evidenced by a distinguished record of research publications, and should have a broad technical background in the construction of radiotelescopes and other instrumentation at millimeter and submillimeter wavelengths. The incumbent should have a Ph.D. in astronomy, physics, or astrophysics, as well as excellent skills in communication and organization, and the ability to work well with other scientists and with support staff in the context of a large technical project.

This is a senior level position, with salary depending upon qualifications and experience.

The **Software and Imaging Leader** will report to the Project Director and will lead the effort to define imaging requirements and develop software. Topics such as zero-spacing requirements, wide field tesselation techniques, calibration in the absence of strong continuum sources, and bandwidth synthesis will be considered in the context of designing the interferometer. In the construction phase, the incumbent will lead the software development effort, especially in the area of novel imaging algorithms, control architecture, data handling and data analysis. The incumbent will work closely with project leaders and staff in the scientific, technical, and receiver areas during the design and construction phases, and will have the needed administrative, technical, and computer support.

The incumbent should have a broad technical and scientific background in astronomical imaging problems and software development, and should have extensive experience in interferometry, millimeter wavelength astronomy, and/or submillimeter wavelength astronomy, as evidenced by a distinguished record of publications. The incumbent should have a Ph.D. in astronomy, physics, or astrophysics, as well as excellent skills in communication and organization, and should work well with other scientists and with support staff in the context of a large technical project.

This is a senior level position, with salary depending upon qualifications and experience.

The **Receiver Scientist** will report to the Receiver Leader and will work in one or several of the following areas: beam optics, SIS junction fabrication, mixer block design and matching, local oscillator generation and injection, intermediate frequency amplifiers and electronics, vacuum and refrigeration systems, analog and digital spectrometers, computer control, and software. The incumbent should have extensive experience in one or more of these areas, and should have an extensive record of both technical and astronomical publications. A Ph.D. in astronomy, physics, electrical engineering, or astrophysics is required.

The position is a 4-year term position, with salary depending upon qualifications and experience. A permanent position in this area is expected to become available at the end of the four-year term, and the incumbent would be encouraged to apply.

Each candidate should send a curriculum vitae, bibliography, statement of research interests and career goals, and the names of three professional references to: **Dr. James M. Moran, Associate Director, Smithsonian Astrophysical Observatory, 60 Garden Street, Cambridge, MA 02138, USA**, by February 28, 1989. Candidates should have each reference send a letter of recommendation to Dr. Moran by the same date. (NW3099)A

UNIVERSITY OF UMEÅ, SWEDEN

invites applications for a position as

PROFESSOR IN PLANT MOLECULAR BIOLOGY

Ref no 91

Applications are invited for a position as full professor in Plant Molecular Biology at the Department of Plant Physiology, available July 1, 1989.

Candidates should have a distinguished record of research in the area of plant molecular biology as well as proven qualities in teaching and leadership. The appointee is expected to conduct and supervise independent research and to participate in graduate teaching at the department.

Applications with curriculum vitae, copies of reprints and preprints and a statement of previous research achievements and teaching skills, all in four copies, should be sent to: University of Umeå, S-901 87 Umeå, Sweden.

For further information, write or call; Professor Gunnar Öquist, Department of Plant Physiology, University of Umeå, S-901 87 Umeå, Sweden. Phone 46-90-165716.

Expiring date for applications is February 24, 1989. (W5817)A

UNIVERSITY OF LIVERPOOL

LECTURESHIP IN IMMUNOLOGY

Applications are invited for the post of "New Blood" Lecturer in the Department of Immunology. The successful applicant will be expected to develop a research programme within the general area of molecular immunogenetics/immunobiology; appropriate experience would be desirable. The Department's major research interests focus on human reproductive, tumour and transplantation immunology. Informal enquiries may be made to Professor P. M. Johnson (051-709 0141, ext. 2749). Candidates will normally be 35 years or under.

Initial salary within the range £9,260–£16,345 per annum on the Lecturer A or B scales.

Applications, together with the names of three referees, should be received not later than 10th March by the **Director of Staffing Services (AS), The University, P.O. Box 147, Liverpool L69 3BX**, from whom further particulars can be obtained. Quote ref. RV/245/N.

An Equal Opportunity Employer. (8267)A

SCHOOL OF PHARMACY
UNIVERSITY OF LONDON

LECTURER IN PHARMACEUTICAL CHEMISTRY

Applications are invited from candidates with research interests in synthetic or other aspects of medicinal chemistry for a Lectureship in the Department of Pharmaceutical Chemistry. The post is tenable with immediate effect and the successful candidate will be expected to contribute to both teaching and research, for which the School has excellent facilities, with opportunities for multidisciplinary and inter-departmental research.

Salary according to the scale for University Lecturers (Lecturer A £9,260–£14,500 + £1,650 L.A.; Lecturer B £15,105–£19,310 + £1,650 L.A.)

Applications, in the form of a CV, and naming three referees, should be submitted to **Mr N J Rampley, Assistant Secretary, School of Pharmacy, 29–39 Brunswick Square, London WC1N 1AX** by end of February. Previous applicants need not apply. (8287)A

The University of Wyoming
RESEARCH ASSISTANT PROFESSOR

A Research Assistant Professor position is available in the Molecular Biology Department. The successful applicant will join a group who are cloning and expressing spider silk proteins. Experience in construction and screening of cDNA libraries, Southern and Northern Blotting and recombinant protein expression desirable. Salary will depend on qualifications and be in the range of $25-30,000.

Applications with a c.v. and three letters of reference should be sent to Dr. Randolph Lewis, Box 3944 Univ. Station, Laramie, WY 82071.

The University of Wyoming is an Affirmative Action/Equal Opportunity Employer. (NW3254)A

RESEARCH FELLOW
POSITION OF EXCELLENCE

DIVISION OF TROPICAL ANIMAL PRODUCTION

TROPICAL CATTLE RESEARCH CENTRE
ROCKHAMPTON, QUEENSLAND
AUSTRALIA

$31003 - $45177

THE PROGRAM: A substantial research group has been assembled at the Tropical Cattle Research Centre to carry out gene mapping studies in cattle and sheep. The National Gene Mapping Centre is also located in Rockhampton. Current projects include defining genetic markers for specific genes, DNA finger printing and the construction of a bovine genetic map.

THE PROJECT: Recent advances permit vectors known as yeast artificial chromosomes to stably incorporate megabase fragments of DNA. This development will greatly facilitate chromosome walking and genomic cloning. The project will research megabase cloning of bovine DNA in yeast with the aim of constructing representative libraries.

THE JOB: The appointee will initiate studies on yeast cloning of bovine DNA involving the isolation of high molecular weight DNA, electrophoretic separation and cloning into yeast vectors. Interaction with other ongoing gene mapping projects will be encouraged.

THE PERSON: Applicants should have a Ph.D or equivalent qualification in molecular biology. Experience in yeast culturing and pulsed field gel electrophoresis is desirable.

CONDITIONS: The initial appointment will be for a period of three years, with Australian Government Superannuation Benefits available. Assistance with relocation will be offered.

APPLICATIONS: Stating relevant personal particulars including details of qualifications and experience, the names of at least two professional referees and quoting reference number POE88 should be directed to:

The Chief,
CSIRO Division of Tropical Animal Production,
Box 5545,
Rockhampton Mail Centre,
Queensland 4702
AUSTRALIA
Fax (079) 36 1034

CSIRO AUSTRALIA

Within four weeks of the date of this publication.

OKLAHOMA MEDICAL RESEARCH FOUNDATION

PROTEIN CHEMISTS AND CELL BIOLOGISTS IN BLOOD RESEARCH

Research positions (postdoctoral fellow to senior research scientists) immediately available for qualified MD's/PhD's to participate in multiple NIH-funded research projects related to interaction of complement and coagulation systems in platelet activation and blood clotting. Prior training or expertise in physical biochemistry, protein chemistry and/or cell biology desired. Position for highly-motivated M.D. desiring basic or applied research training in Transfusion Medicine also available. Contact **Peter J. Sims, M.D., Ph.D., Oklahoma Medical Research Foundation, 825 N.E. 13th Street, Oklahoma City, OK 73104.** An equal opportunity, affirmative action employer. (NW3259)A

UNIVERSITY OF READING
Postgraduate Research Institute for Sedimentology
LECTURESHIP IN PALAEOBIOLOGY

Applications are invited for the post of Lecturer in Palaeobiology with reference to Sedimentology in the newly-created Postgraduate Institute for Sedimentology from 1 September 1989. The appointee will be expected to undertake research in a palaeobiology field directly related to Sedimentology, supervise postgraduate research students, develop appropriate industrial links, and contribute to taught postgraduate and undergraduate courses. The Institute has at this stage no preference regarding the research field, but examples of topics of interest are: micropalaeontology of modern environments, palaeoecology, molecular palaeoecology, taphonomy, environmental palaeobotany, and organism-climate relationships. Initial salary up to £12760 p.a. (Lecturer Grade A) plus USS benefits. Further particulars and application forms (2 copies) available from **Personnel Office, University of Reading, Whiteknights, PO Box 217, Reading, RG6 2AH, telephoine 0734-318751.** Please quote Ref. AC.8905. Closing date 31 March 1989. (8282)A

UNIVERSITY OF CAMBRIDGE
Companion Animal Research Group, Department of Clinical Veterinary Medicine
Effects of kennelling procedures on canine behaviour and welfare
UFAW POSTDOCTORAL RESEARCH ASSISTANT (3 YEARS)

Applications are invited for the above post from persons with appropriate research experience in animal behaviour. Applicants should be under 27, and should also have a valid driving licence. Salary around £10460 pa or at appropriate point on age-related scale.

Letters of application together with cv and the names/addresses of two referees should be sent to **Dr. James Serpell, Director, Companion Animal Research Group, Sub-dept of Animal Behaviour, Madingley, Cambridge CB3 8AA.**

Closing date for applications: 15 March 1989. (8277)A

UNIVERSITY OF LONDON
Department of Thoracic Medicine, King's College and Department of Phamacology, Hunterian Institute, Royal College of Surgeons

Postdoctoral scientist required to join a team of clinicians and basic scientists to study the role of phospholipid derived mediators in acute respiratory diseases in young children. The applicant should have a PhD in Pharmacology, Physiology or Biochemistry. The post is available immediately and the person appointed will work jointly with Dr John Price at King's College Hospital and Professor Priscilla Piper at the Royal College of Surgeons, to whom informal enquiries should be made. The minimum starting salary will be £12,150 and the post is funded intitially for 2 years.

Applicants should send a CV and the names and addresses of two refrees as soon as possible to:—

Personnel Officer, Royal College of Surgeons, 35-43 Lincoln's Inn Fields, London WC2 3PN. (8275)A

ansto

AUSTRALIAN NUCLEAR SCIENCE & TECHNOLOGY ORGANISATION

RESEARCH FELLOW
MATERIALS SCIENCE/ELECTRON MICROSCOPY

Position No. 762

Research Scientist
$A31,003-$A38,045 per annum

Senior Research Scientist
$A39,349-$A45,177 per annum

A vacancy currently exists within the Advanced Materials Program of the Australian Nuclear Science and Technology Organisation (ANSTO) for a research fellowship within the Electron Microscopy Group. The successful applicant will be expected to interact fully with other scientists in the program and will have opportunity to participate in collaborative programs with industry. Current projects include:

- Phase development and crystal chemistry of Synroc, a titanate ceramic for nuclear waste encapsulation.
- Studies of structural changes in minerals and synroc during weathering or hydrothermal dissolution.
- Radiation damage in metamict minerals and neutron irradiated ceramics.
- Advanced ceramics for biomedical and electrical applications e.g. high Tc superconductors, proton conductors etc.
- Remnant life studies of steels.

The fellow will also be encouraged to develop his/her own research projects and/or industrial collaboration, provided such interests fall within the Programs general aims.

The Advanced Materials Program has one JEM 2000 FX TEM fitted with a Gatan TV system and a conventional Si/Li ED spectrometer; and a second JEM 2000 FX fitted with a wide bore pole piece and a thin window detector. Other facilities include a JEOL JSM 6400 SEM, a JEOL JXA 840 analytical SEM, a computer controlled Phillips PW 1050 diffractometer, a Siemens D 500 automatic XRD unit, optical microscopes, a Zeiss quantitative image analysis system, mechanical testing equipment and an extensive ceramics processing laboratory.

The Organisation utilises a salary system based on personal merit for this category of staff. Progression to higher grades is possible as experience, skills, knowledge and personal contributions to the Organisation's programs increase.

Salary depending upon qualifications and experience will be within the above range.

Knowledge, qualifications and Skills
Applications are sought from electron microscopists **and** from materials scientists with experience in analytical TEM techniques. The skills sought include experience with HRTEM, ATEM, image processing, image simulation, materials fabrication, metallurgy, crystal chemistry, mineral dissolution/alteration, structure/property relationships, radiation damage, and electroceramics.

Applicants should have a PhD or equivalent in relevant physical sciences and extensive experience with transmission electron microscopy.

At least two Professional referees should be nominated. It is intended that the skills and experience of the successful applicant will complement those of existing staff.

Employment will be for a term of 3 years, with Australian Government superannuation benefits available.

Contact Officer for further information is Dr K Smith telephone (02) 543 3505 or Fax (02) 543 5097.

Closing date for applications is 17 February, 1989, although applications received after that date may be considered. It is hoped that the successful applicant would begin duties on or before 1/4/89.

Application forms and selection criteria may be obtained by telephoning (02) 543 3064 or writing to the Recruitment Officer, Australian Nuclear Science and Technology Organisation, Private Mail Bag 1, Menai, N.S.W. 2234, Australia, quoting the above position number.

ANSTO IS AN EQUAL OPPORTUNITY EMPLOYER.

BMFT – Förderprogramm Neurobiologie

Das Bundesministerium für Forschung und Technologie beabsichtigt eine Förderung besonders ausgesuchter Projekte der neurobiologischen Forschung (*Beginn: ca. 1. Sept. 1989, Laufzeit: 5 Jahre*). In Frage kommen Projekte aus den Bereichen der molekularen und zellulären Neurobiologie sowie der funktionellen Analyse des Gehirns. Der Leiter einer Projektgruppe kann seine eigene Stelle mitbeantragen. Um die Einrichtung einer Projektgruppe können sich Institutionen oder entsprechend qualifizierte Wissenschaftler in Verbindung mit Institutionen bewerben. Einzelheiten zum Förderprogramm und zur Abfassung von Projektskizzen können unter dem Stichwort "Projektgruppe Neurobiologie" über die Zuständige Stelle:

Naturwissenschaftliches und Medizinisches Institut
an der Universität Tübingen in Reutlingen (NMI)
Gustav-Werner-Str. 3, D–7410 Reutlingen 1, F.R.G.

in Erfahrung gebracht werden. Projektskizzen sind bis zum 15. April 1989 ebenfalls beim NMI einzureichen. (W5810)A

HUMAN GENETICIST

The Department of Molecular Genetics, Biochemistry and Microbiology is searching for a human geneticist particularly an individual who is interested in genetic diseases effecting the cardiovascular or pulmonary system. The appointment is in the tenure tract and can be at any level. Generous space and start up monies are available. In addition, the College has been awarded a Program of Excellence for the Heart, Blood, and Lung Institute. This grant provides supplies and postdoctoral fellow support for this position over the 7 years of the award. The current department has 26 faculty and 50 graduate students and maintains core facilities in tissue culture, DNA technology and transgenic mice.

Interested applicants should submit their curriculum vitae, a short write up of their anticipated research, and names of three individuals who are qualified to judge their abilities to: **Jerry B Lingrel, PhD., Professor and Chair, Molecular Genetics, Biochemistry and Microbiology, University of Cincinnati College of Medicine, 231 Bethesda Avenue, Cincinnati, Ohio 45267-0524.**

Conseil de recherches en sciences naturelles et en génie du Canada

REGISTER OF CANADIANS STUDYING ABROAD

The Natural Sciences and Engineering Research Council of Canada (NSERC) has recently initiated a Register of Canadian postgraduate students and postdoctoral fellows in the fields of natural science or engineering who are currently pursuing studies or research abroad. The object of the Register is to facilitate their return to Canada by providing a means of contact with potential Canadian employers.

Eligibiligy: Canadian citizens and permanent residents of Canada enrolled in a postgraduate degree program or holding a postdoctoral appointment at a non-Canadian university/institute, in the natural sciences or engineering, are eligible to register.

Operation: In conjunction with the Register of students and fellows, NSERC will maintain a list of interested Canadian employers in industries, universities, and government departments. Names and contact addresses of registrants meeting specified qualifications will be provided on request to these employers.

NSERC will provide initial contact between registrants and potential employers; further contact will be the responsibility of the employers. This service is offered free of charge to registrants and potential employers.

Registration: Canadian students and fellows interested in obtaining further information and/or registration forms should contact:

Administrator, Register of Canadians Studying Abroad
Natural Sciences and Engineering Research Council of Canada

ST GEORGE'S HOSPITAL MEDICAL SCHOOL
(University of London)
RESEARCH TECHNICIAN

required to join a team supported by the MRC/Government AIDS Directed Programme to develop laboratory tests for vaccine efficacy. Virological experience clearly an advantage, but work mostly cellular immunology for which training will be given.

Salary in the range £6,636 – £7,828 plus London Allowance per annum.

Further details and an application form from the **Personnel Officer, St George's Hospital Medical School, Cranmer Terrace, London SW17 0RE. Tel 01-672 9944 (ext 56020). Closing date Friday 17 February 1989. Please quote reference no. 15/89.** (8276)A

THE UNIVERSITY OF NEW ENGLAND

Equal Opportunity is University Policy

DEPARTMENT OF BIOCHEMISTRY, MICROBIOLOGY AND NUTRITION

RESEARCH FELLOW – ACIAR

(Re-advertisement)

The position of Research Fellow is funded by the Australian Centre of International Agricultural Research. The successful applicant will be expected to organise and collaborate in research into increasing livestock production from crop residues and to spend periods of each year in India at the Central Institute for Research in Buffaloes, Hisar, or at the National Dairy Development Board, Anand, collaborating with teams of animal scientists. Presently research is underway on improving the nutritional value of straw as a ruminant feed by ammoniation, supplementation and defaunation of the rumen of cattle of straw-based diets.

The applicant should have a background in agricultural science or veterinary science, a higher degree or equivalent qualification. Experience in developing countries would be an advantage but not essential. The appointment will be on an annual basis but funds are available for 3 years in the first instance.

Informal enquiries to Professor R.A. Leng, telephone 61 67 73 2707.

SALARY: $A30,737-$A40,100 per annum.

CLOSING DATE: 17th February, 1989.

POSITION No.: 419.

RESEARCH FELLOW

RESEARCH FELLOW
Enzymologist

(Re-advertisement)

The successful candidate will join a team of microbiologists, molecular biologists and animal nutritionists, investigating means of increasing fibre digestion in the rumen of sheep and cattle.

The enzymologist would be required to investigate the enzymes and rate-limiting steps involved in cellulose breakdown by rumen bacteria. Experience in anaerobic microbiology would be an advantage. The appointment would be for one year in the first instance. The project is funded by the Australian Meat and Livestock Research and Development Committee. The project will be reviewed in 1990.

ENQUIRIES: Dr K. Gregg 61 67 73 2748.

SALARY: $A30,737-$A40,100 per annum.

CLOSING DATE: 17th February, 1989.

POSITION No.: 420.

JUNIOR RESEARCH FELLOW

Microbiologist

(Re-advertisement)

Applications are invited for a grant-funded scientific post tenable in the Department of Biochemistry, Microbiology and Nutrition. The successful candidate will join a team of anaerobic microbiologists, molecular biologists and animal nutritionists, investigating means of increasing fibre digestion in the rumen of sheep and cattle.

The bacteriologist would be required to investigate and compare fibre-digesting bacteria present in the gut of herbivorous animals. Experience in anaerobic microbiology would be an advantage but training can be given. The appointment would be for one year in the first instance.

ENQUIRIES: Dr T. Bauchop 61 67 73 2606.

SALARY: $A22,109-$A25,867 per annum (Grade I).
$A26,617-$A30,360 per annum (Grade II).

CLOSING DATE: 17th February, 1989.

POSITION No.: 421.

JUNIOR RESEARCH FELLOW

Ruminant Nutritionist

(Re-advertisement)

A Junior Research Fellow is required to be part of a research team aiming to improve the efficiency of ruminant animal production through selection or genetic modification of rumen micro-organisms. The research is sponsored by the Australian Meat and Livestock Research and Development Corporation.

The successful applicant must have a PhD in the area of ruminant nutrition and metabolism, and expertise with isotope tracer methodology and kinetic modelling would be an advantage.

ENQUIRIES: Dr J.V. Nolan 61 67 73 2605.

SALARY: $A22,109-$A25,867 per annum (Grade I).
$A26,617-$A30,360 per annum (Grade II).

CLOSING DATE: 17th February, 1989.

POSITION No.: 422.

Applications for the above positions should be addressed to the Staff Officer and include names and addresses of three referees and state position number. Referees should be given a copy of this advertisement and asked to write direct to the Staff Officer by the closing dates and quote position number.

(W5824)A

UNIVERSITY OF OXFORD

In association with Magdalen College

UNIVERSITY LECTURERSHIP IN CHEMICAL PATHOLOGY

Applications are invited for the above post tenable from 1 October 1989. Candidates will have specialised in molecular biology with a strong interest in the application of recombinant DNA technology to medical problems.

The holder of this post will be expected to contribute to advanced teaching in Cell Biology.

The ability to make some contribution to introductory teaching in Pathology, Bacteriology or Virology would be an advantage. Stipend according to age on the scale £9,865 to £20,615.

The successful candidate may be offered a tutorial fellowship at Magdalen College.

Further details may be obtained from

Professor H. Harris, FRS,
Sir William Dunn School of Pathology,
South Parks Road,
Oxford, OX1 3RE,

to whom applications (nine typed copies or one from overseas applicants) with full curriculum vitae, summary of research interests and the names of three referees should be sent by 13 March 1989. (8293)A

The University is an Equal Opportunity Employer

SCOTTISH CROP RESEARCH INSTITUTE

Invergowrie, Dundee DD2 5DA

MOLECULAR BIOLOGIST

HIGHER SCIENTIFIC OFFICER (BAND I) (3-year Appointment) VIROLOGY DEPARTMENT

An HSO is required to study parsnip yellow fleck virus, a novel plai virus which resembles the picornairuses of animals. The objective to determine the nucleotide sequence and gene products of the viru its affinities with other viruses, and the expression of its RNA in plai protoplasts.

Salary scale: £10,026–£13,460 plus
Non-contributory superannuation scheme.

Qualifications: First or upper second class honours degree in a appropriate priate subject, with at least two years' relevant pos graduate research experience, which may be a course of research an study leading to a Ph.D. degree.

The Institute is an equal opportunities employer.

Further paricular may be obtained from Mr I. Paxton, Personn Officer (tel: 0382 562731), to whom a curriculum vitae with th names and addresses of three referees should be sent by Friday 1 February 1989. (8280)A

POSTDOCTORAL POSITION
Molecular Neurobiology

A postdoctoral position is available to analyze the molecula characteristics of cell surface glycoproteins and their role i intercellular communication in the nervous system. Project concern the interaction of contactin (J.Cell Biol. [1988 107:1561-1573) with extracellular and intracellular ligand and the molecular analysis, expression and role of molecule isolated in association with contactin. Candidates witl expertise in biochemistry, molecular biology, cell-, develop mental-, or neurobiology may reply. The La Jolla Cance Research Foundation is located within the scientific commu nity of San Diego.

To apply please submit curriculum vitae, statement o research interests and two letters of recommendation to:

Dr. Barbara Ranscht, La Jolla Cancer Research Foundation 10901 N. Torrey Pines Rd., La Jolla, CA 92037.

An Equal Opportunity/Affirmative Action Employer.

(NW3250)A

RESEARCH OPPORTUNITY IN JAPAN

The Frontier Research Program at the **RIKEN** Institute of Physical and Chemical Research (see Nature 325: 569, 1987) invites applications for postdoctoral positions in the following areas:

— Molecular biology of the immune system and protein chemistry (purification and analysis of proteins) including expression of cloned genes and characterization of gene products at the Laboratory for Molecular Regulation of Aging headed by *Dr. Gabriel Gachelin.*

— Molecular biology of tumor suppresser genes, protein chemistry including characterization of proteins from the brains of Alzheimer patients, and biochemistry, molecular cell biology including eukaryotic cell during proliferation and differentiation at the Laboratory for the Aging Process headed by *Dr. Koiti Titani.*

— Molecular biology of phytochrome, including immunocytochemistry, isolation and analysis of genomic clones *in vivo* footprint analysis and site-directed mutagenetics at the Laboratory for Plant Biological Regulation headed by *Professor Masaki Furuya.*

— Nonlinear optics of organic materials, characterization and device application and organic molecular beam epitaxy technique at the Laboratory for Nonlinear Optics and Advanced Materials headed by *Professor Anthony F. Garito.*

— Protein design and synthesis, and bioelectronics at the Laboratory for the Bioelectronic Materials headed by *Dr. Kevin M. Ulmer.*

Appointments will be initially for one year and may be renewable thereafter.

These Laboratories are located at RIKEN Institute's two establishments in Wako, Saitama and Tsukuba, Ibaraki, on the outskirts of Tokyo.

Candidates should send a detailed curriculum vitae, a list of publications and the names of two individuals who may be contacted for references and summary of research interests to:
Director, Division of the Frontier Research Program,
RIKEN, Wako, Saitama, Japan
Zip code 351–01

SIGNAL TRANSDUCTION IN HUMAN NEUTROPHILS
Department of Chemistry and Biological Chemistry

Applications are invited for the position of Senior Research Officer to work on **signal transduction mechanisms to the cytoskeleton in human neutrophils** with Dr Paul Thornalley. The project is based on the novel and exciting prospect of involvement of the glyoxalase system in cytoskeletal regulation (Biochim. Biophys. Acta **931**, 120, 1987) and involves immunofluorescence microscopy with digital image processing, phosphoprotein technology employed in studies of chemotaxis, phagocytosis and degranulation of human neutrophils. Applicants should have interests in biochemistry and/or cell biology and enjoy working in a multi-disciplinary life sciences laboratory.

The successful applicant can expect to join a lively and enthusiastic research group and contribute to on-going international collaborations. The post is funded by the Wellcome Trust. The appointment will be for three years with salary on the research assistant Grade 1A scale (£9,865 - 15,720).

Informal enquiries may be made to Paul Thornalley (Tel. 0206 873010 direct dial) and further particulars obtained from the Personnel Office (Tel. 0206 873433).

Applications (three copies), including a curriculum vitae and the names and addresses of two referees, should reach the Registrar (R/788/N), University of Essex, Wivenhoe Park, Colchester CO4 3SQ by 28th February 1989.

DEVELOPMENT OF NOVEL ANTI-CANCER DRUGS

Department of Chemistry and Biological Chemistry

Applications are invited for the position of Research Officer, Grade IB, to work on the development of **anti-mitotic agents for cancer chemotherapy, based on the novel and exciting prospect of anti-mitotic activity of S-acylglutathione derivatives.** The project involves synthesis of modified tripeptides, enzyme purification and kinetic studies, and culture of human leukaemia cells. Applicants should have interests in any of peptide synthesis, enzymology and cell culture and enjoy working in a multidisciplinary life sciences laboratory.

The successful applicant can expect to join a lively, enthusiastic and expanding research group working on related subjects and contribute to international collaborations. The post is funded by the Leukaemia Research Fund. Appointment will be for three years with salary on the research assistant IB scale (£8,675 - 11,680), with the opportunity of registering for a higher degree.

Informal enquiries should be made to Paul Thornalley (Tel. 0206 873010) and further particulars obtained from the Personnel Office (Tel. 0206 873433).

Applications (three copies), including a curriculum vitae and the names and addresses of two referees, should reach the Registrar (R/809/N), University of Essex, Wivenhoe Park, Colchester CO4 3SQ by 28th February 1989.

(8319)A

MOLECULAR BIOLOGIST
DEPARTMENT OF DERMATOLOGY
STANFORD UNIVERSITY SCHOOL OF MEDICINE

The Department of Dermatology of Stanford University School of Medicine invites nominations and applications of individuals possessing scientific expertise in the molecular biology of the extracellular matrix for a tenure-track position on its faculty. Candidates should hold the M.D. or Ph.D. degree and present strong evidence of research accomplishments. Applicants should also be committed to the training of post-doctoral fellows in cutaneous biology. The rank of the appointed person will be commensurate with academic qualifications. Stanford University is committed to increasing the representation of women and members of minority groups on its faculty and encourages applications from such candidates. Interested individuals should submit a curriculum vitae and direct correspondence to:

Eugene A. Bauer, M.D.
Professor and Chairman
Department of Dermatology, R–144

RESEARCH FELLOW

(SATELLITE INSTRUMENTATION AND REMOTE SENSING)

$A31,003 - $45,177

DIVISION OF ATMOSPHERIC RESEARCH
ASPENDALE, VICTORIA, AUSTRALIA

THE DIVISION: The Division of Atmospheric Research conducts strategic and applied research into problems concerning the physics, dynamics and chemistry of the atmosphere.

THE PROGRAM: The Remote Sensing Group is concerned with remote sensing of atmospheric and surface parameters. Projects include: the interpretation and application of high resolution meteorological satellite data, the investigation of clouds, aerosols and plumes by lidar; and theoretical and experimental investigation of candidate instrumentation for future meteorological satellites.

A numerical model and a laboratory prototype of an instrument to measure surface pressure from space has been investigated. An airborne prototype is under construction, and test flights on CSIRO's research aircraft are scheduled for July - December 1989.

THE JOB: Initially, to undertake research into the development of the atmospheric pressure sensor and the interpretation of data from the test flights. Thereafter the appointee will have considerable freedom to initiate research within the general field.

THE PERSON: Applicants should have a Ph.D degree or equivalent qualifications in physics together with proven research ability. Experience in general meteorology and, in particular, the theory of radiative transfer would be an advantage.

CONDITIONS: Appointment will be for a term of 3 years. Australian Government superannuation benefits are available.

MORE INFORMATION: Prospective applicants are invited to telephone Dr. Denis O'Brien on 0011 613 586 7662 for further information. Dr. O'Brien can also provide a copy of the detailed job description and selection criteria.

APPLICATIONS: Applications should be submitted by 3 March 1989 and quote Reference Number A1845. They should be framed against the selection criteria, and should state relevant personal particulars including details of qualifications and experience. Applicants should nominate at least two professional referees, and address their application to:

The Chief,
CSIRO Division of
Atmospheric Research,
Private Bag No. 1,
Mordialloc, Vic.,
Australia, 3195.

UNIVERSITY OF OSLO

TWO PROFESSORSHIPS IN GENERAL GENETICS

re vacant at the University of Oslo. Both professorships come un-
er the Faculty of Mathematics and Natural Sciences and are placed
ithin the Department of Biology:

. **Professorship-(salary class 35) in General Genetics (Population Genetics),** vacant from 1 January 1990.

he University is looking for a person with experience from both
eoretical and empirical aspects of Population Genetics and with
trong background in classical Genetics. Preference will be given to
andidates who are using modern techniques, such as DNA-hybridi-
ising, DNA-fingerprinting etc.

he salary payable in class 35 will be NOK 269 710 gross, from which
% will be deducted to cover contributions to the Norwegian Public
ervice Pension Fund.

. **Professorship (salary class 33) in General Genetics (Molecular Genetics),** vacant from 1 January 1989.

he University is interested in applicants with scientific competence
molecular eukaryot Genetics; applicants who have worked with
ie genetics of procaryots and virus will also be seriously evaluated.

he salary payable in class 33 will be NOK 248 757 gross, from which
% will be deducted to cover contributions to the Norwegian Public
ervice Pension Fund.

or both A and B:

urther details concerning the field of study and the responsibility
f the professor, and a description of the working conditions in the
epartment of Biology have been included in a separate statement
hich may be obtained on application to the Secretariat of the
aculty of Mathematics and Natural Sciences, PO Box 1032
lindern, N-0315 Oslo 3, Norway.

he professor will be appointed to participate in teaching and exa-
inations in accordance with the academic regulations in force, and
e or she will be expected to accept, without indemnity, any changes
iat may be made with respect to curriculum, pension scheme and
ompulsory retirement age by Act or by the King with the consent
f the Storting.

/ithin one month of the closing date for applications, candidates
ust send direct to the Secretariat of the Faculty of Mathematics
id Natural Sciences of the University of Oslo:

5 complete sets of the academic works — published or unpublished — that they wish to have taken into account by details of where they have been made public, and 5 copies of the application with any enclosures.

cademic work in progress at the time of the closing date for appli-
itions may however be submitted up to three months after the clo-
ng date, provided the applicant has given notice of this at the time
submitting the other works.

fter the closing date for applications, the University wi'i send
ndidates information concerning the submission of their academic
ork.

eference is also made to the Rules concerning the Procedure for the
ppointment of Professors and Readers, laid down by the Senate,
f the University Act § 18.

pplicants must be able to produce a medical certificate on request.

several applicants are considered to have equal qualifications
ter both the academic/professional and the pedagogical qualifica-
ns have been assessed, the University will rank a female appli-
nt before a male applicant.

pplications are to be addressed to the King and sent with one copy
the list of academic works to **the University of Oslo,** PO Box 1072
lindern, N-0316 Oslo 3, Norway by 1 April 1989.

MEDICAL BIOLOGICAL SCIENCES

POSTGRADUATE RESEARCH OPPORTUNITIES

The School of Medical Biological Sciences comprises the Departments of Human Anatomy and Cell Biology, Physiology, and Pharmacology and Therapeutics. A number of Studentships will be available for research leading to a Ph.D. in the following areas:

Department of Human Anatomy and Cell Biology

1. The role of rigor complexes in anoxic injury of cardiomyocytes (Dr. P. H. Cobbold).
2. The function of specific actin sequences in the dynamics of actin architectures. (Dr. P. Sheterline).
3. *In situ* hybridisation study of transforming skeletal muscle. (Prof. S. Salmons).
4. Proto-oncogene expression in mitogenesis. (Dr. S. Pennington).
5. The mechanism of the calcium signal in mouse oocytes at fertilisation. (Dr. K. S. R. Cuthbertson).
6. Transplantation of foetal neural tissues and neuronal cell lines into mammalian brain. (Dr. Y. S. Allen).
7. Role of plasminogen activator in human bone remodelling. (Dr. J. A. Gallagher).
8. Laminin expression in the nervous system. (Dr. D. Edgar).

Contact: Dr. P. H. Cobbold
Tel: (051) 794 5470

Department of Physiology

9. Ion channels in secretory cells. (Prof. O. H. Petersen).
10. Biosynthesis of brain-gut peptides. (Prof. G. J. Dockray).
11. Control of exocytosis in secretory cells. (Dr. R. D. Burgoyne).
12. Central nervous regulation of the upper gastrointestinal tract. (Dr. R. J. Gayton).
13. The somatosensory input to the rat striatum. (Dr. D. C. M. Taylor).
14. Excitatory amino acid neurotransmitters. (Dr. J. Garthwaite).
15. Structure-activity relationships of regulatory peptides. (Dr. R. Dimaline).
16. Regulation of calcium release and calcium influx in exocrine acinar cells. (Dr. D. V. Gallacher).

Contact: Dr. R. D. Burgoyne
Tel: (051) 794 5305

Department of Pharmacology and Therapeutics

17. Metabolism of cyclosporin. (Dr. D. J. Back).
18. Blood-borne factors in myocardial ischaemia. (Dr. S. J. Coker).
19. Control of mast cell sensitization. (Dr. J. W. Coleman).
20. Pharmacological and parasitological studies of antimalarial agents derived from *Artemesia annua*. (Dr. I. G. Edwards).
21. Effect of drug binding inhibitors on anion transport by the kidney. (Dr. W. E. Lindup).
22. Retrograde axonal transport of specific proteins in peripheral neuropathy. (Dr. W. G. McLean).
23. Effect of chemical modification on drug toxicity using isolated human enzymes and target cells. (Dr. B. K. Park).
24. Effect of thyroid dysfunction on the multiple forms of UDP-glucuronyl transferase in man and the rat. (Dr. A. K. Scott).

Contact: Dr. W. E. Lindup
Tel: (051) 794 5556

Further information may be obtained by writing to the named contacts at **The University of Liverpool, P.O. Box 147, Liverpool L69 3BX,** enclosing a curriculum vitae with the names and addresses of two referees, and indicating the research area(s) of interest. Candidates wishing to be considered for a Wellcome Trust Prize Studentship should apply as soon as possible.

(8291)A

UNIVERSITY of LAUSANNE

Our Institut de Police scientifique et de Criminologie has an opening for an

Associate Professor in Forensic Science

The position entails teaching, academic research, R & D and consultancy at local and international level. The candidate must be capable of fitting into a small, dedicated team (2 professors, 10 scientific and technical assistants).

The fields of interest of the candidate may be diverse (methodology, chemical criminalistics, firearms identification, arson, explosion, questioned document examination, computer security, drugs of abuse and drug intelligence, forensic biology exluding serology). Twelve months after appointment, the teaching should be given proficiently in french.

Candidates should send their curriculum vitae to the Dean, Faculté de Droit, BFSH 1, 1015 Lausanne, Switzerland, by March 31, 1989.

For information contact:

Professor Pierre Margot — Institut de Police scienfifique et de criminologie — Place du Château 3 — CH — 1005 Lausanne. (W5830)A

RESEARCH FELLOW
BIOSPHERE MODELLER

$A31,003 - $45,177

DIVISION OF ATMOSPHERIC RESEARCH
ASPENDALE, VICTORIA, AUSTRALIA

THE DIVISION: The Division of Atmospheric Research conducts strategic and applied research into problems concerning the physics, dynamics and chemistry of the atmosphere.

THE PROGRAM: The Global Atmospheric Change program aims to predict and understand the mechanisms responsible for changes in the chemical and physical character of the regional and global atmosphere, particularly where these changes may affect the Australian community. One project is concerned with generating realistic scenarios and predictions of local and regional climates under conditions of changing global climate, and to estimate the impact of such climates on the biosphere and human activity in collaboration with the International Geosphere-Biosphere program.

THE JOB: To develop climate-biosphere interface models at two levels: (i) simple biosphere models capable of responding to climate change and increasing CO_2 concentrations, which will provide appropriate changing lower boundary conditions for climate models, and (ii) crop or ecosystem models capable of describing the changes in biospheric productivity and composition which would result from climatic change.

THE PERSON: Applicants should have a Ph.D. or equivalent qualifications in plant biology/physiology and/or ecology, with a strong interest in mathematics or the physical sciences; or a Ph.D. or equivalent qualifications in mathematics/atmospheric sciences with a strong interest in plant biology/physiology and/or ecology. Experience in computer modelling is also essential.

CONDITIONS: The appointment is for a term of three years. Australian Government superannuation benefits are available.

MORE INFORMATION: Prospective applicants are invited to contact Dr. Barrie Pittock on (0011 61 3) 586 7527, Fax 586 7600, for further information. Dr. Pittock can also provide a copy of the duty statement and selection criteria.

APPLICATIONS: Applications should be submitted by 3 March 1989 and quote reference number M8959. They should be framed against the selection criteria and should provide details of relevant personal particulars, including qualifications and experience. Applicants should nominate at least two professional referees, and address their applications to:

AT89/04a

DEAN OF THE COLLEGE OF BIOLOGICAL SCIENCES
THE OHIO STATE UNIVERSITY

Applications and nominations are invited for the position of Dean of Biological Sciences. As chief executive officer, the Dean is responsible for academic leadership, resources management, and productive synergistic relationships with other Colleges in the University including Agriculture, Mathematical and Physical Sciences, Medicine, Pharmacy and the Biotechnology Center. The Dean also plays a central role in a range of development and public relations activities. Candidates should have an earned Ph.D. degree and a record of research accomplishment that warrants a faculty appointment at the rank of full Professor in the College. The deanship is a twelve-month appointment available September 1, 1989. Salary is negotiable and commensurate with background and experience. Nominations or letters or application, curricula vitae, and names, addresses, and telephone numbers of four references should be addressed to:

Dean C. William Kern, Chair, Biological Sciences Search Committee, Office of Academic Affairs, The Ohio State University, 203 Bricker Hall, 190 North Oval Mall, Columbus OH 43210.

The Search Committee will begin screening dossiers on February 15, 1989 and will continue to receive nominations and applications until the Dean is selected.

The Ohio State University is an Equal Opportunity/Affirmative Action Employer. Women and minorities are encouraged to apply. (NW3269)A

THE UNIVERSITY OF WESTERN AUSTRALIA
Perth

LECTURER IN ANATOMY AND HUMAN BIOLOGY
(Ref. A09/89

Applications are invited for a tenurable lectureship. The Department has strong teaching and research commitments in the Faculties of Science and Medicine. Extensive research, both basic and applied is being undertaken in such areas of human biology as (a) evolution, genetics, variation and ecology (especially primates); (b) comparative and functional anatomy, including biomechanics and morphometrics; (c) reproductive biology and (d) neurobiology. Techniques available include light and electron microscopy, surgical procedures, stereology, computer modelling, image and data analysis of various types. Applications are sought from individuals in the first two of the general areas outlined above and with any of the above techniques. Duties will include research development supervision and co-ordinatic courses, lecturing, labor and tutorial teaching. further details contact the of Department, Professor Oxnard, (09) 380 3298.

Salary range: A$30,73 A$40,100 p.a. Benefits inc superannuation, fares to Pert appointee and dependent fa removal allowance, study and long service leave. Condi of appointment will be specifi any offer of appointment w may be made as a result of advertisement.

Written applications qu reference number, telep number, date of birth, quali tions, and experience and names and addresses of thre erees should reach the Dire Personnel Services, The Un sity of Western Australia, lands 6009, Australia, by 3 M 1989.

Equal Employment Oppo ity is University Policy

(W5820)

SHELL RESEARCH LIMITED, SITTINGBOURNE, KENT

Microbial Physiologist

The Sittingbourne Research Centre of Shell Research Ltd has had a long term involvement in many aspects of Microbial Biotechnology. Current interests include investigations of the potential of micro-organisms to transform organic compounds either to high added value chemicals or to innocuous substances of low environmental impact. These studies of biocatalysis and biodegradation are being carried out by multidisciplinary teams which include chemists, biochemists, physiologists, molecular biologists and ecologists.

You will be a scientist with a degree in biochemistry, microbiology or a similar discipline. You should have a strong interest in the biodegradability of organic chemicals and in biodegradative mechanisms employed by micro-organisms, particularly mixed cultures. Some experience with model activated sludge or other biotreatment processes, with a knowledge of the performance of micro-organisms within mixed communities, would be beneficial.

The Research Centre is a modern, well equipped laboratory on a 500 acre rural site in Kent. We offer attractive salaries, good sports and social facilities and a staff restaurant.

If you are interested in the above position please write or telephone for an application form, quoting reference number SRC1/89 (Microbial Physiologist) to: Mrs Diane King, Personnel Division, Shell Research Limited, Sittingbourne Research Centre, Sittingbourne, Kent ME9 8AG. Telephone: (0795) 412290. Closing date for applications is 16th February 1989.

CAREERS OF CONSEQUENCE

(8323)A

Scientific Computing Posts

The Daresbury Laboratory, operates a Synchrotron Radiation Source and a Nuclear Structure Facility, which are used by university groups from most parts of the country and abroad. In support of these facilities the Laboratory provides computing services.

Scientific Computing Ref DL/91

There are vacancies in the Synchrotron Radiation Computing Group for three Scientific Computing Posts.

The duties include maintenance and development of data acquisition programs that control experimental stations at the Synchrotron Radiation Source and support and development of data analysis packages for applications in the project areas of Soft X-Ray Spectroscopy, Non-Crystalline X-Ray Diffraction and Molecular Chemistry.

Experimental station control software run mainly on DEC LSI11/23 computers under RT-11. The data analysis codes run on DEC VAX computers under CMS, one with an attached FPS-264 array processor, or on the Laboratory's Convex C2 mainframe systems and working knowledge of Fortran and basic numerical analysis methods would be an advantage.

The successful candidates will join an existing team of scientific applications programmers but will be associated with one of the three projects and will be expected to liaise with in-house staff and external users. Active participation in the research programme would be encouraged.

For further details contact Dr E Pantos (0925) 603275.

Computational Scientist Ref DL/92

There is a vacancy in the Collaborative Computational Project for Protein Crystallography (CCP4).

The duties include maintenance and development of packages, which can be used by all scientists involved in protein structure determination by X-Ray crystallography. The packages run on DEC VAX computers under VMS, or on the Laboratory's mainframe CONVEX 220 computer under UNIX.

The person appointed will collaborate with protein crystallographers at Daresbury and from university groups in implementing new methods of data analysis and structure determination. Applicants should have experience in scientific data analysis. Solving computational problems and liaising with the protein crystallography community are important aspects of this work.

For further information contact Dr K Henrick (0925) 603528.

• Qualifications

Minimum qualifications required are:-
Higher Scientific Officer – Degree plus 5 years relevant experience or 1st or 2nd Class Honours degree plus 2 years post graduate experience.
Scientific Officer – Degree HNC/HND or equivalent.

• Pay

Appointments will be made at the Scientific Officer or Higher Scientific Officer grade depending on qualifications and experience. Salary is in the range £8,574 to £13,460 with further increments depending on performance.
The superannuation scheme is non-contributory.

For an application form please quote the relevant reference number and contact:
The Personnel Officer, Daresbury Laboratory, Warrington WA4 4AD.
Telephone (0925) 603467
(24 hour answering service).

CLOSING DATE:
Thursday 16th February 1989

SCIENCE & ENGINEERING RESEARCH COUNCIL

ASSISTANT PROFESSOR
MOLECULAR BIOLOGY OF RETROVIRUSES

The Division of Biology at Kansas State University has a tenure-track position available at the assistant professor level effective August 1989. Applications are invited from investigators with postdoctoral experience in the molecular biology of retroviruses and/or related oncogene expression. The division has a strong program in biologicl research, excellent facilities, and NCI Graduate Training Grant in Virology and Tumor Biology, and a distinguished faculty with several millions of dollars in extramural grants. The successful candidate will be expected to establish a vigorous and creative program in retrovirus and/or oncogene research, and to participate in graduate and undergraduate instruction. Candidates should apply by 15 February 1989 by submitting curriculum vitae, a brief description of future research plans, and having three letters of reference sent to:

Terry C. Johnson
Division of Biology, Ackert Hall
Kansas State University
Manhattan, KS 66505

KSU is an Equal Opportunity/Affirmative Action Employer

(NW3268)A

Research Fellow/ Staff Scientist

Applications are invited for a post-doctoral research fellow or staff scientist appointment in the Division of Geological and Planetary Sciences at Caltech. Applicants should have a Ph.D. in analytical chemistry, chemical physics or experimental physics with a sound background in laser spectroscopy and a strong interest in the development and application of laser ionization techniques. Research areas include development of laser resonance ionization for elemental and isotopic measurements in geological materials, isotopic and chemical analyses of primitive meteorites, kinetics of solid state diffusion in natural and synthetic silicates and oxides. Individuals with a particular interest in instrumental analysis and in the development of new and innovative research projects are encouraged to apply. Send CV and letter outlining research interests to **Prof. G.J. Wasserburg, Chairman, Division of Geological and Planetary Sciences, Mail Code 170-25, California Institute of Technology, Pasadena, CA 91125.** *Caltech is an equal opportunity/affirmative action employer.*

INICAL INVESTIGATION MANAGER

e Medical Research Division of American Cyanamid Com- ny a diverse Pharmaceutical/ emical Company, has its Inter- ional Clinical Research Centre urope) at Richmond, Surrey.

To strengthen our clinical inves- ation group, we wish to appoint Clinical Investigation Manager o would have responsibility for management and co-ordina- n of the Company's projects in rope involving Phase I to Phase clinical research. A major re- irement of the job is the ability work with Research Physicians d Clinical Scientists in the des- and conduct of clinical studies d with the staff responsible for analysis of the research data.

It is expected that candidates l be educated to degree level d either have 2 to 4 years' exper- ce in clinical research with the armaceutical industry, or be rking in an academic environ- nt with some experience in the ical trials area.

The incumbent will be required travel abroad within Europe d to the USA. The salary and nditions of employment, inclu- g a company car will reflect the portance of the position within ernational Clinical Research.

To apply, please write with l CV to Carolyn Osbourne, Per- nel Officer, Cyanamid (UK), reham Road, Gosport, Hamp- re, PO13 0AS, or ring our ansa- one on Fareham (0329) 230941 an application form any day er 12 noon. (8289)A

DIRECTOR

British Geological Survey, Keyworth, Nottingham
Salary up to £33,800

The Natural Environment Research Council is seeking a Director for the British Geological Survey to succeed Mr Geoffrey Larminie, OBE, upon his retirement in August 1989. The Director will be responsible to the Director of Earth Sciences, NERC, for the scientific leadership and management of BGS which has a staff of about 750 at its headquarters in Keyworth (Nottingham), Edinburgh and four small regional offices. The annual budget of BGS is about £24m.

Applicants should have an international reputation in the Earth Sciences and previous experience in the management of geological personnel and projects. Experience of working with both industry and government will be an advantage.

Starting pay on appointment will be on the scale £32,219 to £33,819, with a further increment to £35,457 depending on performance. A non-contributory pension scheme is available, plus a generous annual leave allowance. Some assistance towards relocation costs may be available.

Application forms and further information may be obtained from Lorraine Nowlan at the address given below or by telephoning (0793) 411500 or (0793) 411531. Completed applications, including a full CV should be sent to Lorraine Nowlan, NERC, Polaris House, North Star Avenue, Swindon, Wiltshire SN2 1EU, by 28 February 1989.

The Natural Environment Research Council is an Equal Opportunities Employer.

UPPSALA UNIVERSITY

Applications are invited for a tenured

PROFESSORSHIP IN ZOOPHYSIOLOGY

at the University of Uppsala, Sweden (starting salary: from 210 000 SEK).

Subject area for the chair:
"The position is in the field of animal physiology and integrated functions in a broad sense such as the physiology of organs and organisms and cell physiology aiming at analytical studies of physiological mechanisms and adaptation."

The application should be directed to the Swedish Government and should be received at the Registrar's Office, Uppsala University, Box 256, S-751 05 Uppsala, Sweden, *no later than February 22, 1989*.

The applicant should submit a curriculum vitae (duly signed and witnessed), a short written account of his/her scientific and pedagogic activities, certificates and such other documents as to which the applicant wishes to refer, a list of scientific publications and the scientific publications referred to numbered and sorted according to the list of publications. All in four copies.

For further information, please contact the Dean of the Division of Biology, telephone 00946-18-17 45 26.

(W5837)A

PROTEIN CHEMIST

We have one or more openings for post-doctoral protein chemists to explore some new ideas for the site-specific modification of antibodies for diagnosis and therapy, particularly of cancer. The experimental programme is well funded from Industrial and charitable sources and is expected to give considerable scope for novel, useful research. The department is equiped with all necessary apparatus (in particular, a major mass-spectrometric facility dedicated to protein work, an ABI sequencer, and an ABI peptide synthesizer). We have excellent clinical and industrial contacts. Salary approx. 50'000–60'000.— Swiss Francs. The appointment is for two years in the first instance: one post is available immediately.

Please send C.V. and representative reprints or preprints to:

Prof. R. E. Offord,
Department of Medical Biochemistry,
University Medical Centre,
1 rue Michel-Servet,
1211 Geneva 4, Switzerland,
Tel. 22'90'15. (W5832)A

Sigma Tau

a leading Italian Pharmaceutical Company is establishing a new Cardiovascular Research Centre in the Milan area

The following positions are vacant:

Head of team in vivo Pharmacology

This is a position for an experienced and innovative pharmacologist, head of a team of approximately ten, able to coordinate with other multidisciplinary teams. The primary focus of this team is on animal models of genetic cardiovascular diseases for which a long lasting experience already exists within the people of the centre. Pathophysiological alterations and the effect of new drugs will be studied on these animals in collaborations with other teams dealing with medicinal chemistry, genetics, protein chemistry, molecular biology, cell pharmacology and clinical studies in man with similar diseases.

Molecular Biologist

This is a position for a candidate having at least 4-5 years of experience in a relevant area of molecular biology, head of a small team, able to coordinate with the other teams. The primary focus of this team is on the identification and characterization of the genes causing the cardiovascular diseases of the animal models studies within the centre. The possibility to study humans with similar diseases is also encouraged.

Senior Research Chemist

This is a position for a candidate having a proven wide experience in organic synthesis and computerized medicinal chemistry able to take the responsibility of a small group of chemists working in collaboration with other chemical research groups.

A highly competitive salary is offered for these three positions. Fringe benefits will also be commensurate with experience and qualifications. Relocation assistance is available when appropriate.

Please send a detailed curriculum vitae to:

Dr. R. Colasante

the widest international selection of jobs in science — EVERY WEEK

SENIOR BIOCHEMISTS
RESEARCH BIOCHEMISTS
RESEARCH CHEMISTS & ANALYTICAL ORGANIC CHEMISTS
SENIOR MECHANICAL DESIGN ENGINEER
ENGINEERING MANAGER
PROJECT LEADER
SYSTEMS ANALYST & SENIOR PROGRAMMERS
CHROMATOGRAPHY/ELECTROPHORESIS ENGINEERS

We are a UK Biotechnology start-up company with the aim of becoming the leading worldwide provider of advanced products and services for carbohydrate analysis. Our products are based on powerful and proprietary technology from the University of Oxford. We have immediate openings in the Instrument Systems Group, Fine Chemicals Group and Research Services Group.

Your enthusiasm, professionalism, superior technical and research skills and flexibility to work in a multi-disciplinary team on an aggressive schedule will make you a successful candidate.

If you would like to play a key role in a fast growing, innovative and friendly organisation, apply now. We are searching for top percentile professionals and offer highly competitive renumeration and benefits package, including equity participation.

SENIOR BIOCHEMISTS

Oxford GlycoSystems specialises in the manufacture of carbohydrate related fine chemicals and provides a unique and exceptional set of research services. The company places great emphasis on the quality of its scientists and is currently seeking:

Senior Biochemists of exceptional calibre for supervisory positions in the Research and Research Services groups. The position in the Research group will involve responsibilty for developing new products for the Fine Chemicals business, while the position in the Research Services group involves responsibility for the entire spectrum of company business, from customer contact to actual analysis of samples. For both positions, a proven record in analytical biochemistry and significant managerial experience are required. A knowledge of techniques for glycoprotein and/or carbohydrate analysis is preferred, but not essential. These positions represent a unique opportunity for senior biochemists to create and manage their own group of scientists, while also being active at the bench, and free from the routine tasks of maintaining and administering a laboratory.

RESEARCH ASSISTANTS

Research Assistants will report directly to Group team leaders in the Research and Research Services. Candidates should have an honours degree (or equivalent), and considerable experience in protein chemistry. An above average salary and benefits package are available.

RESEARCH BIOCHEMISTS

The Research Biochemist will join a young and dynamic group of scientists engaged in research on glycoprotein structure and function. The successful candidate will soon head their own sub-group. An honours degree and Ph D, or equivalent experience, are required.

BIOMEDICAL INSTRUMENTATION ENGINEERING

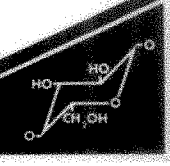
Applications are invited to join OGS as the **Manager** of Engineering of the Instruments Systems Group. This newly formed company specialises in Bioanalytical instruments used in the Biotechnology Research industry and is producing the world's first carbohydrate sequencer.

Experience as a manager of product development in the area of scientific or medical instruments is absolutely required. Experience in managing five of the following disciplines of engineering is required:
software: machine control and user interface;
detection systems: light or other radiation;
analogue electronics: small signal simplification and conditioning;
digital electronics: I/O, CPU board design;
hydraulics: small tubes and valves carrying chemicals (eg, HPLC);
mechanical apparatus: small scale mechanisms.

Additionally, the successful candidate will have had experience managing the entire product development life cycle from conception to volume shipments of scientific instruments. He/she must have five years experience managing a multi-disciplinary group of ten or more professional engineers and budget responsibility experience in excess of £1 million per year. A talent for working effectively with marketing will be highly regarded.

OGS is searching for a top percentile individual with excellent communication skills and an ability to build up a dedicated team of product champions.

We are also looking for technical professionals with product development experience in the following fields: microprocessor controlled analytical and laboratory instruments, real time process systems, analog design and development, software, optics, physics, miniature fluid handling, mechanisms and mechanical packaging. If you have mechanical engineering experience, send us your c.v.



If you fit any of the job descriptions listed please let us know. If you know someone who fits any of these job descriptions, let them or us know. If you would like to work for any of these people once we find them, let us know that too.

Apply enclosing a full c.v. to:

Oxford GlycoSystems

Professional Staffing, Oxford GlycoSystems Limited,
Unit 4, Hitching Court, Blacklands Way,
Abingdon Business Park, Abingdon, Oxon,
OX14 1RG.
Tel: 0235–553066.

POSTDOCTORAL RESEARCH POSITION

Collaborative Research Programme: Dyson Perrins Laboratory, Oxford University in association with Celltech Limited

This postdoctoral research position, based at the Dyson Perrins Laboratory, Oxford, represents an exciting opportunity to collaborate with Celltech – Europe's foremost independent biotechnology company. The research involves the synthesis of prodrugs designed as part of a novel approach to cancer chemotherapy. Experience in synthetic organic chemistry would be an advantage. The post is to start as soon as possible and will be funded until April 1991. Salary will be up to £15,095 pa; starting point depending on age and qualifications.

Applicants should send a curriculum vitae to Dr A J Pratt, Dyson Perrins Laboratory, South Parks Road, Oxford OX1 3QY and should ask two referees to write directly on their behalf to Dr Pratt.

The international journal of science with 500,000 readers throughout the world seeks

A TALENTED BIOLOGIST

Essential qualifications:

- A sound education in some field of biology.
- A critical and lively interest in science in general.
- A sense of literacy.
- Reseach experience.

Applications are invited from people seeking a career in the communication of science. The successful applicant will join the team responsible for assessing and editing biology manuscripts, initially (at least) in London. There will be opportunities for contributing to *Nature* in other ways. Research experience in neurobiology would be particularly welcome, but those with other interests should not be deterred from applying.

To apply, please send your *curriculum vitae* to the Editor, with a detailed account of your education, research experience and literacy skills, at 4 Little Essex Street, London WC2R 3LF, or 1137 National Press Building, Washington, DC 20045, as soon as possible and before 24 February. (8317)A

Research Associate

to conduct research as follows:

determine the roll of the cell and mutation in the hemagglutinin (HA) gene in determining host range; investigate the role of glycosylation of he HA in determining how well new clinical isolates replicate in cell cultures; investigate feasibility of cloning HA genes directly from clinical sample to determine if the number of oligosaccharides on the HA or the position at which the HA is glycosylated is changed when the virus is grown in cell culture. Salary: $20,900 per year/40 hour week. Requirements: Ph.D., or equivalent, in cellular or molecular biology. Applicant must have at least two publications in nucleic acid (DNA or RNA) protein interaction research. Applications to: **Consuelo Walker, ALC Specialist, Job Service, 505 Washington, St. Louis, Missouri 63101**. Please refer to Job Order Number 237719. (NW3274)A

The David Mahoney Institute of Neurological Sciences (INS) of the University of Pennsylvania is recruiting a

Developmental Neurobiologist

at the rank of Assistant or Associate Professor. We are particularly interested in people working at the molecular or cellular level, either in genetics or in other aspects of nervous system development. The INS has over 100 members and already has several excellent laboratories working on cellular, molecular and biochemical aspects of neural development and regeneration. Applicants should send their curricula vitae and the names and addresses of three references to: **Michael E. Selzer, MD/PhD Department of Neurology Hospital of the U or PA Philadelphia, PA 19104-4283.** ***University of Pennsylvania is an Equal Opportunity/Affirmative Action***

Opportunities in Drug Discovery Research in Japan

Pfizer Central Research at Nagoya, Japan, is offering excellent career opportunities in our expanding drug discovery research programs. The laboratories located 35 km south of Nagoya city are an integral part of Pfizer Central Research worldwide and Pfizer Taito Co. Ltd., a Pfizer Inc. subsidiary. We are seeking Japanese scientists at the Ph.D. level with degrees in Biochemistry, Immunology, Pharmacology, Microbiology, and Organic Chemistry, and 1-3 years of post-doctoral or industrial experience. In addition to strong technical expertise, all positions require extensive English communication skills and computer literacy. Specific requirements are as follows:

Immunologist/Biochemist

The successful candidate will have work expertise in cytokines, cell surface receptors, and lymphocyte activation. Initially, he or she will be responsible for developing *in vitro* assays aimed at accomplishing several goals, including evaluation of the role of different mediators in the immune response. Knowledge of tissue culture techniques is essential.

Pharmacologist

A broad knowledge of, and experience with, various animal models of inflammation is essential. The successful candidate will be responsible for developing animal models of arthritis and autoimmunity. Some background in general pharmacology and cellular immunology is desirable.

Microbiologist

A strong background in biochemistry and molecular biology of micro organisms is essential. Knowledge of taxonomy is desirable.

Natural Products Chemist

The successful candidate will become a member of our discovery fermentation group. Experience in modern isolation techniques and spectral methods is essential.

Organic Chemist

Applicants should have extensive expertise in organic synthesis. Responsibilities include design and synthesis of biologically active compounds. Keen interest in the biological aspects of drug discovery is essential.

Pfizer Taito offers a competitive salary and excellent benefits, including a relocation package. Qualified applicants should submit their resumes and a brief description of their research accomplishments to **Mr. Kenji Takamatsu, Director of Personnel, Pfizer Taito Co. Ltd, P.O. Box 226, 1-1 Nishi-Shinjuku 2-Chome, Shinjuku, Tokyo 163, Japan.** (W5784)A

CELL AND MOLECULAR PHYSIOLOGY

The Department of Physiology invites applications for tenure track faculty positions at the level of

Assistant Professor

Outstanding candidates working in any area of contemporary physiology will be considered, but those in smooth muscle, reproduction and development, endocrinology, sensory transduction, and the cardiovascular system are encouraged to apply. Successful candidates are expected to have a Ph.D. or M.D. with post-doctoral experience, to provide evidence that they can pursue a vigorous, independent research program and to participate in our teaching program.

Resources and an excellent environment exists for developing an academic career within an interactive community. Interested scientists should send their curriculum vitae, a statement of present and future research interest, and names of three references to: **Ernest M. Wright, D.Sc. Professor and Chairman, Department of Physiology, UCLA School of Medicine, Los Angeles, CA 90024-1751.**

The University of California is an Equal Opportunity Affirmative Action Employer. (NW3265)A

EXECUTIVE DIRECTOR
QUATERNARY SCIENCES CENTER, DESERT RESEARCH INSTITUTE
UNIVERSITY OF NEVADA SYSTEM

The Quaternary Sciences Center of the Desert Research Institute is seeking an Executive Director of national reputation to provide administrative and scholarly leadership for its expanding basic and applied research programs in Anthropology, Archaeology, History, Paleobotany, Paleozoology and Quaternary Geology. The Center has an agenda to expand its research into improving understanding of global environmental change in arid environments. The successful applicant must have demonstrated the administrative and interpersonal skills required to foster the productivity and creativity of a small group of research scientists and to be an effective advocate for the Center. Applicants should have significant research achievements in the Quaternary sciences. Experience in archaeology is desired and a Ph.D. is preferred. Salary is state-funded in the $75,000 to $80,000 range negotiable commensurate with applicant's qualifications and experience.

The Desert Research Institute is the statewide research division of the University of Nevada System, Research is managed in five centers: Atmospheric Sciences, Biological Sciences, Energy and Environment Engineering, Water Resources and Quaternary Sciences. DRI's annual budget now exceeds 16 million and is growing at 15% annually. The Quaternary Sciences Center (formerly the Social Sciences Center) has an annual budget of over a million dollars in grants and contracts and a full-time staff of 21 professionals and technicians. Center research is concentrated on arid and semi-arid lands of the world with particular emphasis on the Intermountain West; opportunities exist for developing additional programs in Quaternary studies. Applications should include a résumé and statement of interest. Initial screening of applications will begin by May 1, 1989. Placement is desired by July 1, 1989 although a later date is negotiable. Applications should be addressed to **Dr. Peter Wigand, Chairman, Quaternary Sciences Center Executive Director Search Committee, Desert Research Institute, University of Nevada System, P.O. Box 60220, Reno, NV. 89506.** For further information call Dr. Peter Wigand at (702) 673–7387. *The Desert Research Institute is an affirmative action equal opportunity employer.* (NW3275)A

Director

Parke-Davis Research Institute
Sheridan Park Research Center, Mississauga, Ontario, Canada

The Parke-Davis Research Institute is dedicated to toxicological research and safety testing of new pharmaceuticals as part of the worldwide drug development efforts of the Parke-Davis Pharmaceutical Research Division, Warner-Lambert Company.

We are seeking a strong individual with a DVM, MD or Ph.D. in Toxicology or equivalent advanced degree in science. Certification in Pathology, Toxicology or equivalent is desired.

This senior research management position is directly responsible for the operation, planning and conduct of toxicology studies by a large group of scientists. A minimum of 8-10 years of research experience in toxicology/pathology of laboratory animals from safety evaluations is desired, preferably with experience in a multi-disciplinary environment of toxicology research. Working knowledge of all aspects of toxicity testing, including general toxicology, pathology, mutagenesis, clinical laboratory sciences and reproductive toxicology will be necessary, together with knowledge of Good Laboratory Practice regulations, worldwide testing and regulatory guidelines and experience in regulatory affairs.

This leadership position requires an exceptional person with long-term growth potential, excellent publication record, national/international recognition and demonstrated record of independent biochemical, toxicological or biological research.

Excellent written and oral communications skills and interpersonal effectiveness with management background are essential. This senior scientist would also have experience in successfully leading scientists, encouraging open communications and working in a complex matrix organization, actively interacting with senior research management, and having administrative control of a large budget and scientific projects.

This high quality laboratory constitutes a part of the worldwide toxicology research efforts and the position reports to the Vice President, Pathology and Experimental Toxicology, located at the division research headquarters in Ann Arbor, Michigan, USA.

Enjoy an excellent program of benefits, relocation and compensation, in addition to a high quality of life environment, which makes this position very attractive for a long-term career with Warner-Lambert.

In compliance with Canadian Government Regulation, preference will be directed to Canadian citizens or permanent residents.

Join this respected worldwide leader in pharmaceutical research. Send curriculum vitae and references in confidence to: Mr. T. Romps, Human Resources Representative, PARKE-DAVIS Pharmaceutical Research Division, 2800 Plymouth Road, Ann Arbor, MI 48105, USA.

CONSULTING

U.S. scientific consulting firm offering assistance in analysis of data and communication of findings in written reports and public presentations to a variety of forums seeks Ph.D.'s in biological and biochemical sciences and M.D.'s interested in worldwide consulting opportunities. Disciplines of interest include epidemiology, biostatistics, toxicology/pharmacology, cancer research, pathology, immunology, allergy, etc., and any of the medical specialties. Applicants will provide assistance on various projects. The position is intended for those people looking to supplement ongoing activities. Travel can be minimized. Retired individuals are welcome as are all academic professionals.

Please reply with résumé and rate structure to: **Chief Executive Officer, Suite 206, 3421 M Street, N.W., Washington, DC, USA 20007.**

(NW3272)A

ASSISTANT ENTOMOLOGIST

Full-time, tenure-track, 100% research. Develop research program on the management and/or eradication of tephritid fruit fly pests. Minimum Qualifications: Ph.D. degree (by closing date) in entomology or related field from an accredited university. Knowledge and experience with IPM, proper pesticide use, statistical methods. Demonstrated communication skills. Position located on Kauai Island. Available 1 May 1989. CV, reprints, official transcripts & three letters of references to **Dr. Ronald F.L. Mau, Entomology Department, University of Hawaii, 3050 Maile Way, Honolulu, HI 96822** by March 15, 1989. Details (808) 948-7063; Fax # (808) 948-6442. EOE/AA

(NW3273)A

UNIVERSITY OF EDINBURGH

Department of Forestry and Natural Resources

Post-Doctoral Research Fellowship

PLANT PHYSIOLOGIST

Applications are invited for an 18-month post-doctoral position, with possible extension to 3 years, based at the Edinburgh Research Station of the Institute of Terrestrial Ecology. The successful applicant will work closely with tropical tree improvement projects led by Dr Roger Leakey and in collaboration with tree physiologists at the University of Edinburgh. The position, funded by Shell Research Ltd., is for investigations into the sources of variation in rooting ability in tropical Eucalypts and, subsequently, for the development of techniques to propagate difficult-to-root clones. Experience in environmental physiology is desirable.

Salary range £9,305-14,825 (min. age 27 £11,015) depending on age and experience.

Further particulars may be obtained from the **Personnel Office, University of Edinburgh, 63 South Bridge, Edinburgh EH1 1LS.** Applications should also be sent to this address together with names of two academic referees to arrive no later than 23rd February, 1989. Please quote reference No. 5632. (8298)E

POSTDOCTORAL FELLOWSHIP

available now to study repair of 06-methylguanine in DNA and human tumor suppressor genes in the laboratory/clinical collaborative program of the Molecular Genetics and Carcinogenesis Laboratory of The Cross Cancer Institute. Two years with third possible. Background in DNA repair and molecular techniques advantageous. $23,815–$30,449.

Send curriculum vitae and names of three references to **Dr. Rufus S. Day, III, Cross Cancer Institute, 11560 University Ave., Edmonton, Alberta, T6G 122, Canada.** (NW3229)E

LINCOLN COLLEGE
University College of Agriculture
New Zealand

POSTDOCTORAL FELLOWSHIP

Applications are invited for a Postdoctoral Fellowship in the laboratory of Professor D. W. Bullock to work on *trans*-acting factors involved in the regulation of gene expression by progesterone. Applicants should have a Ph.D or equivalent in biochemistry or molecular biology with experience in DNA cloning and sequencing. The post is funded by a Medical Research Council grant for three years at an initial salary of NZ$35,000. per annum.

Lincoln College has made a major commitment to molecular biology and the appointee will join a new and expanding research group with strong interests in gene transfer and transgenic animals.

Applications should include a curriculum vitae, list of publications and names and addresses of three referees.

Conditions of Appointment may be obtained from the undersigned, with whom applications close on 13 February 1989.

G. A. Hay,
Registrar,
Lincoln College,
Canterbury,
New Zealand.
(W5816)E

UNIVERSITY OF NOTTINGHAM MEDICAL SCHOOL
Department of Physiology and Pharmacology

POSTDOCTORAL FELLOWSHIP

Applications are invited for a Wellcome Trust Postdoctoral Fellowship to investigate the regional haemodynamic effects of central neuropeptides in hypertension. The position is available for two years in the first instance, and would be best suited to a person with experience of the appropriate techniques.

Applicants should send their curriculum vitae and the names and addresses of 2 referees to: **Dr S M Gardiner, Department of Physiology and Pharmacology, Medical School, Queen's Medical Centre, Nottingham NG7 2UH, Tel: 0602 421421 Ext 3344.**

Closing date 28th February 1989. (8273)E

UNIVERSITY OF LEICESTER
DEPARTMENT OF BIOCHEMISTRY

(1) RESEARCH ASSOCIATES

TWO post-doctoral fellows are required to join a team which has recently isolated cDNAs encoding the complete sequence of the cytoskeletal proteins vinculin and alpha-actinin (Biochem.J 245(1987)595; J.Biol. Chem. 262(1987)17623; Cell 52(1988)159). Interest in these proteins stems from the observation that they are associated with actin in cell-cell and cell-matrix adherens junctions, structures which are disrupted in tumour cells.

Projects will include the use of (1) site-directed mutagenesis to define binding domains in these proteins (2) expression systems for the purification of protein fragments for crystallization studies (3) genomic cloning to establish the origin of protein isoforms.

(2) ONE YEAR POST-DOCTORAL TRAINING FELLOWSHIP

The post, which is associated with the above projects, is ideally suited for someone wishing to gain experience in recombinant DNA technology.

Applicants should have a Ph.D. in Biochemistry or related discipline. Experience in DNA technology is desirable though not essential, as training is available for highly motivated candidates of proven ability. The posts are available for a maximum of three years. Starting date not later than April 1st 1989.

Salary according to age and experience, on scale IA: £9,865 to £15,720.

Applications including a detailed c.v. and the names of two referees to Dr. D.R. Critchley, Department of Biochemistry, University of Leiceter, Leicester LE1 7RH (Tel. no. 0533 523477). (8264)E

THE ROYAL VETERINARY COLLEGE
University of London
Department of Veterinary Pathology

POSTDOCTORAL RESEARCH FELLOWSHIP

A three year post is offered to develop an anti-idiotype vaccine against porcine paravovirus to control reproductive losses. Experience with monoclonal antibody production and some molecular biology would be an advantage.

The appointment will be for a term of three years, subject to a satisfactory annual report.

Interested persons are encouraged to get in touch with Dr N Edington.

SALARY SCALE, University Research Grade 1A, ranging from £11,515 to £17,370 per annum. Starting salary according to age and experience.

Application form from the **Assistant Secretary (Personnel), The Royal Veterinary College, Royal College Street, London NW1 0TU (tel no: 01-387 2898).** (8288)E

EMBO

EUROPEAN MOLECULAR BIOLOGY ORGANIZATION

SHORT TERM FELLOWSHIPS

in molecular biology

The European Molecular Biology Organization awards, to scientists working in Europe and Israel in the field of molecular biology and allied disciplines, short term fellowships of one week up to three months duration. The fellowships are to support collaborative research between laboratories in different countries and provide a travel grant and subsistence allowance. Applications may be made at any time and are decided upon soon after the receipt of application.

Applications for exchanges between laboratories within any one country cannot be considered. Fellowships involving transatlantic travel are awarded only in exceptional circumstances. Inquiries should be accompanied by a self-addressed adhesive label.

Application forms and further details may be obtained from **Dr J. Tooze, Executive Secretary, European Molecular Biology Organization, 69 Heidelberg 1, Postfach 1022.40, F.R.G.** (W5706)E

EMBO

European Molecular Biology Organization

LONG TERM FELLOWSHIPS IN MOLECULAR BIOLOGY SPRING 1989 AWARDS

Next deadline: 10 February 1989

EMBO long term post-doctoral fellowships are awarded to promote the development of molecular biology and allied research in Europe and Israel. To be eligible a candidate must hold a doctorate degree and the exchange must involve a laboratory in Western Europe or Israel. EMBO fellowships are not, however, awarded for exchanges between laboratories within any one country. Long term fellowships are usually awarded initially for one year, but with the possibility of renewal for a second year. In cases of exceptional scientific merit, however, the selection committee can award a 2-year fellowship. The fellowship comprises a return travel allowance for the fellow and any dependents and a stipend and dependents' allowance.

Since the selection procedure may include an interview, candidates are requested to respect the deadline for complete applications which is 10 February 1989. Successful candidates will be notified of their awards immediately after the meeting of the selection committee, which is on 17 April 1989.

Application forms and further details may be obtained from **Dr. J. Tooze, Executive Secretary, European Molecular Biology Organization, Postfach 1022.40, 69 Heidelberg 1, F.R. Germany.** Inquiries should be accompanied by a self-addressed adhesive label. (W5559)E

UNIVERSITY OF BIRMINGHAM
SCHOOL OF BIOCHEMISTRY

Postdoctoral Research Fellowship (Ref BC1975)

Graduate Research Associateship (Ref BC1976)

Applications are invited for the above positions to work on the genetic basis of reduced sulphur-oxidation. The aim of the project, which is funded for three years by an MRC grant to Dr R H Waring, is the characterisation of the enzyme system controlling S-oxidation in man, and will involve protein purification and the construction and screening of cDNA libraries. This will be linked with clinical studies at the Queen Elizabeth Hospital, Birmingham on correlations with restriction fragment length polymorphisms and chronic liver disease. The project will start on or after 1 April 1989. Candidates for the Research Fellowship should have experience in the techniques of molecular biology. Candidates for the Research Associateship should hold a good honours degree in the Life Sciences and have an interest or experience in protein purification. Registration for a higher degree may be possible.

For further particulars of the above posts and an application form, telephone 021–414 6383 quoting reference number BC1975 or BC1976. Applications (3 copies) should be sent to the **Senior Assistant Registrar, Faculty of Science, PO Box 363, Birmingham B15 2TT** by 20 February 1989.

AN EQUAL OPPORTUNITIES EMPLOYER. (8271)E

THE LONDON HOSPITAL MEDICAL COLLEGE
(University of London)
MOLECULAR BIOLOGIST
Post-doctoral Fellowship/Pre-doctoral Research Assistantship

Available from January 1989 to work on a 2 year MRC funded project to find new ways to express AIDS virus antigen, in eukaryotic cells. Experience in molecular biology techniques would be an advantage. The successful candidate will join an active research team housed in a very well equipped suite of laboratories in the Department of Medical Microbiology.

Informal enquiries can be made by telephoning Dr A Coates on 01-377 7259.

Applications including CV and the names of two referees should be sent to:

Dr A Coates
Dept of Medical Microbiology
The London Hospital Medical College
Turner Street London E1 2AD

within 2 weeks of the date of this advertisement. (8270)E

AFRC Post-Doctoral Research Fellow

Salary Scale: £10,071 to £13,779

Applications are invited for a Post-Doctoral Research Fellowship, funded by the Agriculture and Food Research Council for a period of 3 years, to investigate mechanisms of signal transduction between perception of light and induction of flowering in higher plants. The work will be supervised jointly by Dr. P. Lumsden (Lancashire Polytechnic) and Dr. A. Hetherington (Lancaster University).

Application forms and further particulars are obtainable, quoting reference number AA/555, from Personnel Services, Lancashire Polytechnic, Preston PR1 2TQ. Tel: (0772) 262027 (24 hour answerphone)

Closing Date:
17th February, 1989.

ANTI-CANCER FOUNDATION OF THE UNIVERSITIES OF SOUTH AUSTRALIA HANSON FELLOWSHIP IN CANCER RESEARCH

Applications are invited from males and females for a Fellowship in Cancer Research. The occupant can undertake studies in any clinical or basic field of cancer research, although the Foundation would give some preference to a suitable person working in the area of Radiation Oncology.

The successful applicant will work in South Australia in either a Hospital Research Laboratory or University Department, and may take up the Fellowship as soon as convenient after 1 June 1989.

ELIGIBILITY: The Hanson Fellowship is intended to support persons below age 35 who are well established in a research career, as assessed by published works and reports of referees.

HOW TO APPLY: Applicants should first correspond with the head of a department in one of the relevant institutions in South Australia and construct a research project which is acceptable to that department and to the applicant's own interests and previous experience.

Applications should be submitted directly to the Foundation, and should include two copies of a detailed research project and of the candidate's curriculum vitae, which should include a list of published work, grants received and outline of previous research experience. The names of three referees should be included.

SELECTION: Selection will be based on an assessment of the applicant's record and the scientific worth of the research project. An interview will be conducted with the applicant (or nominee if the applicant resides outside Australia) following satisfactory reports by outside assessors.

SALARY AND CONDITIONS: The salary being offered will commence between AUS$28,118 and AUS$40,100 depending on past experience and qualifications and will thereafter follow the appropriate Research Salary Scales of the Universities of South Australia. The three year period of appointment is not renewable.

Maintenance Grant: up to AUS$3,000 per year. The institution where the work is carried out will determine all other conditions of employment.

Applications should be addressed to: The Chief Executive Officer, Anti-Cancer Foundation, PO Box 160, North Adelaide, SA 5006, telephone (08) 267 5222.

Closing date for applications: 24 March 1989. (W5808)E

ALCOHOL, DRUG ABUSE AND MENTAL HEALTH ADMINISTRATION
NATIONAL INSTITUTE OF MENTAL HEALTH

FELLOWSHIPS IN BASIC AND CLINICAL NEUROSCIENCE

An extensive basic science and clinical research component of the NIMH Intramural Research Programs is located at the NIMH NEUROSCIENCES CENTER AT SAINT ELIZABETH'S in Washington, D.C. under the leadership of Drs. Rex Cowdry, Carl Merrill, Daniel Weinberger, and Richard Wyatt. This program conducts a broad range of neuroscientific investigations, including studies in: molecular neurobiology; neurochemistry of amines; peptides and receptors; CNS mitochondrial studies; identification of disease-specific proteins; neuropathology; neuropsychopharmacology; CNS tissue transplantation; neurovirolgy-immunology (e.g., studies of neurotropic viruses including variants of HIV); brain imaging (e.g., CT, MRI and SPECT); electrophysiology (e.g., computerized EEG analysis); development of new diagnostic methods; neuropsychological evaluation of psychosis and dementia; and drug trials in schizophrenia and other neuropsychiatric disorders.

The program invites applications from physicians and scientists for Medical Staff Fellow ($32,000), Research Staff Fellows ($20,000-$38,000), or Visiting Fellow ($20,000-$23,000) positions. Staff Fellows must be U.S. citizens with a doctoral degree. Initial appointments are for two years with further renewals possible. Visiting Fellows may be resident or non-resident aliens with a doctoral degree and no more than three years of relevant post-graduate experience. Visiting Fellows are appointed for one year with possible renewals for two additional years.

Interested candidates should send a curriculum vitae, a brief statement regarding experience and research interests, and the names of three references to:

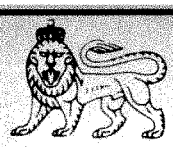
INTERNATIONAL CANCER RESEARCH FELLOWSHIP



The Hayashibara Mutual Aid Fund, a non-profit making organization within the Hayashibara Group announces a fellowship program. Two awards will be made annually. Fellowship will be taken up at the newly opened Fujisaki Cell Center which is devoted for the basic and applied research related to the problems in human cancer. The fellowship is normally made for one year and is renewable for up to five years. The fellowship will be expected to commence within six months of the announcement of the awards. The awards are for high quality research work in one of the three categories described below.

1. Fundamental Leukemia-Lymphoma Research,
2. Cytokine-Lymphokine Research,
3. Hematopoietic Cell Cultures.

Qualified person who has a Ph.D., an M.D. or equivalent qualifications will be awarded on merit to suitably qualified research proposal and experiences. Additional information and application forms will be obtained from: **Jun Minowada, M.D., Director, Fujisaki Cell Center, 675–1,Fujisaki, Okayama 702, Japan.** (W5829)E

SMITHSONIAN POSTDOCTORAL FELLOWSHIPS IN MOLECULAR EVOLUTION AND PLANT PHYSIOLOGY

Postdoctoral Fellowships in Molecular Evolution and Plant Physiology are available for research to be conducted at two or more of the following Smithsonian Institution bureaus: National Museum of Natural History (Washington, D.C.); National Zoological Park (Washington, D.C.); Smithsonian Tropical Research Institute (Panama); and Smithsonian Environmental Research Center (Maryland). Stipends are $24,000 annually, including travel. Tenures are from 12 to 14 months. DEADLINE: May 1. Notification: August 1. For further information and application forms write: **Office of Fellowships and Grants, Desk M, Suite 7300, 955 L'Enfant Plaza, Smithsonian Institution, Washington, D. C. 20560.** (NW3262)E

KING'S COLLEGE LONDON
(University of London)

MRC Medical Research Council

Research Studentships
Biomolecular Sciences Division & MRC Cell Biophysics Unit

Applications are invited from final-year undergraduates (and others appropriately qualified) in departments of biochemistry, molecular biology, immunology, chemistry, physics and related disciplines for research studentships in the various sections of the Division and in the MRC Cell Biophysics Unit. In addition, four of the following research projects will be guaranteed a studentship, which will be allocated early:

Biophysics (Drury Lane) & Immunology (Kensington) Sections
Chromatin structure and the control of transcription
The structural basis of muscle contraction

Biochemistry Section (Strand & Kensington)
Membrane stability at low temperatures
Signal transduction mechanisms regulating lipolysis in intact and permeabilised erythrocytes
Neurotoxic amino acids, protein metabolism and cellular degeneration
Mechanisms of tissue damage in arthritis and in cardiac disease
The use of bacterial expression vectors to study gene expression in differentiating germ cells
Advanced spectroscopic studies of transition-metal centres in enzymes

Prospective candidates must obtain the details before applying and these may be freely obtained as follows:

For Biochemistry from:

Dr M Cannon, Biochemistry Department, King's College London, Strand, London WC2R 2LS (Telephone: 01-836 5454, extension 2674 FAX 01-836 5454, extension 2400)

For Biophysics, Immunology and the MRC Unit from:

Miss P A Wright, Biophysics Laboratories (King's College London, 26-29 Drury Lane, London WC2B 5RL (Telephone: 01-836 8851; FAX: 01-497 9078)

(8285)F

LUDWIG INSTITUTE FOR CANCER RESEARCH
MIDDLESEX HOSPITAL/UNIVERSITY COLLEGE BRANCH

PhD Studentship

The Institute is a superbly equipped Research Laboratory (Director Dr M D Waterfield) located in a newly refurbished building close to the Middlesex Hospital. There are seven groups working in the general areas of growth control and cell signalling in relation to carcinogenesis, differentiation and development. PhD Studentships are available beginning in October 1989. The group leaders and their research interests are as follows:—

PETER PARKER: the structure and function of signal transducing molecules and their role in 'normal' and neoplastic growth.

JEREMY BROCKES: molecular basis of cell patterning in limb development and regeneration.

MICHAEL WATERFIELD: structure and function of growth factors and receptors.

PAUL STROOBANT: purification and analysis of growth and differentiation factors, and their role in initiation, growth and metastasis of tumour cells.

MARK NOBLE cellular and molecular control of development, regeneration and neoplasia in the central nervous system; oncogene function and regulation of differentiation.

JIM WOODGETT: analysis of growth regulatory molecules: emphasis on regulators of oncogenes and transducers of growth factors.

PARMJIT JAT: molecular regulation of cell growth, immortalisation, transformation and senescence.

Interested students should apply as soon as possible to:
SECRETARY TO THE ADMINISTRATOR
LUDWIG INSTITUTE FOR CANCER RESEARCH
91 RIDING HOUSE STREET
LONDON W1P 8BT
Tel: 01-436 8441

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF CLINICAL BIOCHEMISTRY

TWO RESEARCH STUDENTSHIPS including **THE ELLIE BARKER RESEARCH STUDENTSHIP** funded from industrial and private sources are available for 3 years from 1st October, 1989. Each provide a personal grant of £4,000 per annum. One is to study the molecular cell biology of membrane traffic pathways in human cells with Dr J. P Luzio and the other to study the molecular biology of androgen — responsive genes of human hair follicles with Dr G. T. E. Kealey. Potential applicants with, or expecting to obtain, at least upper second class honours degrees should write for further particulars to **Dr. Luzio or Dr. Kealey at the Department of Clinical Biochemistry, University of Cambridge, Addenbrooke's Hospital, Hills Road, Cambridge CB2 2QR.** (8302)F

UNIVERSITY OF SUSSEX

RESEARCH STUDENTSHIPS

Applications are invited for two Ph.D. studentships available in October 1989 for candidates who have, or expect to obtain, first or upper second class degrees and are highly motivated towards research.

1) EUKARYOTIC MOLECULAR BIOLOGY in the laboratory of Dr. Alan Lehmann in the MRC Cell Mutation Unit. The successful applicant will join an active research group working on the cloning of human and other eukaryotic DNA repair genes. Applications including a c.v. and the names of two referees should be sent to: **Dr. A.R. Lehmann, MRC Cell Mutation Unit, University of Sussex, Brighton BN1 9RR (tel. 0273-678122)** from whom further details can be obtained.

2) MOLECULAR MICROBIOLOGY in the laboratory of Dr. Brian G. Spratt in the Microbial Genetics Group. An SERC Antibiotics/Recombinant DNA Initiative Ph.D. Studentship is available to work on the molecular basis, or molecular epidemiology, of penicillin resistance in clinical isolates of *Streptococcus pneumoniae.* A c.v. and the names of two academic referees should be sent to **Dr. Brian G. Spratt, Microbial Genetics Group, School of Biological Sciences, University of Sussex, Brighton BN1 9QG (tel. 0273-678309)** from whom further particulars can be obtained.

Applications for these studentships should be received by 10th March 1989. (8313)F

Cancer Research Campaign

POSTGRADUATE RESEARCH STUDENTSHIPS

As part of its continuing support for Cancer Research, The Cancer Research Campaign (CRC) has available the following PhD studentships to work within CRC laboratories and research groups. Studentships will be available from 1 October 1989. *In addition to the normal Research Council stipend the CRC studentships carry an additional £1,000 and full running expenses in support of the research.* Applications are invited from recent graduates or from final year undergraduates in relevant subjects — normally applicants should hold or expect to gain a first or upper second class honours degree.

CRC LABORATORIES, UNIVERSITY OF NOTTINGHAM — 2 studentships
Colorectal cancer antigens — **Professor R W Baldwin**
Idiotypic antibodies in immunoregulation — **Professor R W Baldwin**

CRC EXPERIMENTAL CANCER CHEMOTHERAPY RESEARCH GROUP, ASTON UNIVERSITY, BIRMINGHAM — 2 studentships from:
DNA sequence-specific recombinant molecules — **Professor M F G Stevens**
Membrane signalling-protein kinase C isoforms — **Dr A Gescher**
Tumour cell differentiation (extracellular matrix effects) — **Dr J A Hickman**
Tumour-host relationships (cytokines responsible for weight loss) — **Dr M J Tisdale**

CRC DEVELOPMENTAL TUMOURS RESEARCH GROUP, UNIVERSITY OF OXFORD — 2 studentships
Genetic analysis of teratocarcinoma cell differentiation — **Dr M Pera**
Regulation of IGF-11 gene expression — **Professor Graham FRS**

CRC FORMULATION UNIT, UNIVERSITY OF STRATHCLYDE — 1 studentship from:
Formulation of stable i.v. suspensions and emulsions of insoluble compounds or prodrugs — **Dr W R Vezin**
Prediction of solubility of slightly soluble compounds using molecular graphics — **Dr W R Vezin**

CRC LABORATORIES, DEPARTMENT OF CANCER STUDIES, UNIVERSITY OF BIRMINGHAM — 1 studentship from:
Antigenic epitopes of Epstein-Barr virus latent proteins analysed by T-cell cloning — **Professor A B Rickinson**
Characterisations of adenovirus E1 proteins responsible for malignant transformation — **Professor P H Gallimore**
T-cell receptor gene rearrangements and leukaemogenesis in ataxia telangiectasia patients — **Dr A M R Taylor**

CRC HUMAN CANCER GENETICS RESEARCH GROUP, UNIVERSITY OF CAMBRIDGE — 1 studentship
Molecular genetics of inherited cancer — **Dr B A Ponder**

BEATSON INSTITUTE FOR CANCER RESEARCH, GLASGOW — 3 studentships
The use of transgenic mice in studies on oncogenesis and differentiation — **Dr A Balmain**
Cell interaction via gap junctions in normal and neoplastic tissues — **Drs Finbow and Pitts**
Purification of novel growth factors from transformed cells — **Dr B Ozanne**

INSTITUTE OF CANCER RESEARCH, SUTTON, AND LONDON — 3 studentships
Mechanisms of *ras* oncogene transformation — **Dr C Marshall**
Sensitivity of human tumour cells to radiation: underlying molecular mechanisms — **Drs G Steel and T Macmillan**
Synthesis of some S-adenosyl-L-homocysteine derivatives and their nucleoside precursors — **Drs M Jarman and P Serafinowski**

PATERSON INSTITUTE FOR CANCER RESEARCH, MANCHESTER — 5 studentships
Growth factors in intestinal cells — **Drs G S Evans and M Mackett**
Cloning of mammalian and viral DNA repair genes — **Drs E Littler and G P Margison**
Novel anticancer drugs that disrupt microtubules — **Dr A McGown and Professor B W Fox**
Cell surface markers in cervical neoplasia — **Dr P L Stern**
Cellular adhesion and extracellular matrix in haemopoiesis — **Professor T M Dexter and Dr J T Gallagher**

CRC GRAY LABORATORY, NORTHWOOD, MIDDLESEX — 1 studentship
Studies of DNA Repair Processes — **Professor J Denekamp**

Candidates should write indicating in which project they are interested. Letters including a C.V. and names and addresses of 2 academic referees should be sent to:—

MRS J EASTWOOD (STUDENTSHIP SECTION)
CANCER RESEARCH CAMPAIGN,
2 CARLTON HOUSE TERRACE
LONDON, SW1Y 5AR

(8300)F

UNIVERSITY OF CAMBRIDGE
DEPARTMENT OF BOTANY
SERC funded PhD Studentship

Applications are invited for a 3-year PhD studentship to work on the purification of a chlorophyll biosynthesis enzyme from peas. The ultimate aim is to isolate cDNA and genomic clones for the enzyme, in order to study its expression. Applicants should have a good Honours degree in Biochemistry, Molecular Biology or a related subject. The studentship, which is funded by the SERC, will start as soon as possible, and in any case before 11th May 1989.

Applicants should send curriculum vitae and the names of two referees to Dr A G Smith, Department of Botany, University of Cambridge, Downing Street, Cambridge CB2 3EA, by **24th February 1989.**

(8257)F

UNIVERSITY OF CAMBRIDGE DEPARTMENT OF BOTANY

PhD Studentships

The department offers research training leading to the degree of PhD in a number of areas of plant biology. Studentships in the following disciplines are funded by the SERC:

Regulation of Plant Metabolism **Chloroplast Molecular Biology**
Genetics and Molecular Biology of Plant-Pathogen Interactions
Plant Ultrasctructure **Ion Transport in Plants** **Guard Cell Physiology**
Plant Taxonomy **Experimental Mycology** **Developmental Biology**
Molecular Genetics of Chlorophyll Synthesis

Supervisors include: *Dr T ap Rees, Dr D Briggs, Dr P Echlin, Dr JC Gray, Dr DE Hanke, Dr HJ Hudson, Dr DS Ingram, Dr K Johnstone, Prof EAC MacRobbie, Mr PD Sell, Dr AG Smith and Dr PF Yeo.*

Applications are invited for studentships in the above areas of research, tenable from October 1989. Further details of the projects available, and application forms, may be obtained from Dr AG Smith, Department of Botany, University of Cambridge, Downing Street, Cambridge CB2 3EA, to whom applications should be sent by **6th March 1989.** Information regarding research projects in Tropical and Temperate Ecology, Physiological Ecology and Quaternary Research can be obtained from the same source. (8258)F

University of Leicester
Department of Biochemistry

CELLTECH RESEARCH STUDENTSHIP

Applications are invited for a special postgraduate research studentship which has been created by Celltech, Europe's foremost independent biotechnology company. The research programme will involve close collaboration between University scientists and their counterparts at Celltech, and will be focused on a study of factors influencing protein stability and the susceptibility to degradation by proteolytic enzymes *in vivo* and *in vitro*. Candidates should have, or expect to receive, a first or upper second-class honours degree (or equivalent qualifications) in a relevant subject and practical experience in enzymology. The appointment will be for a period of 36 months at a (tax-exempt) stipend of £3,500 *per annum*. In addition the award includes a travel allowance and the payment of University fees for registration for study for the PhD degree (UK and EEC nationals only).

Applications with the names of two referees should be send to Professor W. V. Shaw,
Department of Biochemistry, University of Leicester,
Leicester LE1 7RH. (Tel: 0533 523469).

UNIVERSITY OF MANCHESTER
DEPARTMENT OF CHEMISTRY
GLAXO RESEARCH STUDENTSHIP IN SYNTHETIC ORGANIC CHEMISTRY

Applications are invited for a research studentship to work with Professor E.J. Thomas on the total synthesis of a group of complex biologically active macrocyclic compounds. Applications should have, or expect to have, at least a 2.1 honours degree in chemistry. The post is funded by Glaxo Group Research and the stipend will be at the postgraduate studentship level, i.e. £3125 at present. Applications including a c.v. and the names and addresses to two referees should be sent as soon as possible to

Professor E.J. Thomas, The Department of Chemistry, The University, Manchester M13 9PL, from whom further particulars may be obtained. (8218)F

ASSISTANTSHIPS

UNIVERSITY OF DURHAM
DEPARTMENT OF CHEMISTRY
SENIOR POSTDOCTORAL RESEARCH ASSISTANTSHIP

Applications are invited for a Senior Postdoctoral Research Assistantship, tenable forthwith for a period of at least one year, to work with Dr. M. R. Bryce and Dr. D. Parker on a SERC supported project in collaboration with Cookson Group PLC. Candidates should have experience either in synthetic chemistry or in polymer chemistry.

Informal enquiries may be made by telephoning (091) 374 3133 or 3118.

The salary will be on the RA IA scale within the range £9,865–£11,680.

Further particulars may be obtained from the **Registrar, Science Laboratories, South Road, Durham, DH1 3LE (Tel. No. (091) 374 2263)** to whom applications (three copies), including the names of three referees, should be sent not later than *Friday, 10th March, 1989* (quoting ref. C2 stating title of post).

(8295)P

UNIVERSITY OF DURHAM
DEPARTMENT OF PHYSIC
POSTDOCTORAL SENIOR RESEARC ASSISTANTSHIP

Applications are invited fo SERC funded Postdoctoral Ser Research Assistantship tena for three years from 1st Ap 1989 for work in Observatio Cosmology. Main interests the Cosmology Research Gro are in the determination of large scale structure of universe and in the formatic clustering and evolution of ga xies and of QSO's.

Informal enquiries may be ma to Dr. R. Fong (Tel. No. (091) 3 2157).

The salary will be on the RA scale within in the range £9,86 £11,680.

Further particulars may obtained from the **Registr Science Laboratories, Sou Road, Durham, DH1 3LE (Tel. N (091) 374 2263)** to whom applic tions (three copies), includir the names of three referee should be sent not later th *Friday, 17th February, 19* (quoting ref. P3 stating title post). (8303)P

NORDISK UK GRANT 1989

APPLICATIONS ARE INVITED FOR THE SEVENTH NORDISK UK GRANT

The Grant is intended to further research within the field of insulin-dependent diabetes and growth disorders in the United Kingdom. Awards for clinical and non clinical research are intended mainly as starter funding, usually for younger researchers, rather than covering the full-time salaries of research workers.

The Grant is given by Nordisk Gentofte A/S, the manufacturing division of Nordisk Insulinlaboratorium, a non-profit Foundation by Danish Royal Charter established in 1923.

The value of the 1989 Grant is £25,000 in total.

The successful applicants will be selected by an independent Board. It is unlikely that any single award will exceed £10,000.

For an application form and copy of the Statutes of the Grant please contact:

Nordisk UK Grant, c/o Nordisk-UK,
Nordisk House, Garland Court, Garland Road,
East Grinstead, West Sussex RH19 1DN

The closing date for receipt of completed applications is 22 March 1989.

(8306)H

THIS GRANT IS ADMINISTERED AS PART OF THE NORDISK-UK PROFESSIONAL PROGRAMME

WORKSHOPS

EMBO WORKSHOP

ILLEGITIMATE RECOMBINATION

MAY 28-31 1989 — PARIS, FRANCE

The goal of the workshop is to promote communication between scientists interested in mecanisms and consequences of recombination between DNA sequences of short or no homology.

Among the invited speakers are:
B. ALBERTS (USA), W. ARBER (SWITZERLAND), D.E. BERG (USA), S. BRON (THE NETHERLANDS), J. CHAMPOUX (USA), M. CHANDLER (FRANCE), C. M. CROCE (USA), R. DEONIER (USA), K. DRLICA (USA), H. IKEDA (JAPON), R. KAHMAN (FRG), R. KOLODNER (USA), A. LANDY (USA), D. LEACH (GB), D. LILLEY (GB), B. LLYOD (UK), D. MATHIEU-MAHUL (FRANCE), S. W. WATSON (USA), C. McHENRY (USA), M. RADMAN (FRANCE), L. RIPLEY (USA), R. T. SCHIMKE (USA), R. SCHMITT (FRG), H. SCHREMPF (FRG), F. STAHL (USA), J. WILSON (USA).

The number of participants will be strictly limited to 60. The registration fee will be 500 French Francs. A limited number of fellowships may be available for junior scientists. Applications including CV and research interests should be sent before April 1st, 1989 to **Dr S. D. EHRLICH, LABORATOIRE DE GENETIQUE MICROBIENNE, INRA-DOMAINE DE VILVERT, 78350 JOUY EN JOSAS, FRANCE (Tel: 33-1 34 65 25 10, Fax: 33-1 34 65 22 73).**

Request for Applications

GENE THERAPY AND CYSTIC FIBROSIS

The Cystic Fibrosis Foundation invites investigator-initiated grant applications on the fundamental scientific issues associated with applying gene therapy to cystic fibrosis (CF).

This request is intended to encourage innovative and meritorious projects that can advance the study of CF gene therapy while the search for the CF gene continues. Research areas responsive to this request include, but are not limited to:

- Identification of appropriate airway cells for therapeutic replacement of defective CF genes;
- Development and risk assessment of vector systems for delivering the normal allele of the CF gene into airway cells;
- Development of model systems for examining the scientific, safety and technical issues associated with CF gene therapy.

Research approaches and models must be directly relevant to the application of gene therapy to CF. Applicants may request support for up to three years; funding levels will be commensurate with the scope of projects.

The deadline for submission of applications is **July 1, 1989.** For further information and application forms, please contact **Dr. Robert J. Beall** or **Ms. Dale Glass** at the

Cystic Fibrosis Foundation

(NW3257)H

UNIVERSITY OF WALES COLLEGE OF MEDICINE TENOVUS INSTITUTE FOR CANCER RESEARCH AND UNIVERSITY OF LEICESTER

(DEPARTMENTS OF ANATOMY AND MOLECULAR BIOLOGY) RESEARCH SCHOLARSHIP

Required for studies on the regulation of growth factor gene expression by steroid hormones during development. The position is for 3 years leading to a higher degree. Candidates should have a good degree in a relevant biological science and have an interest in molecular biological and endocrinological aspects of development and proliferation. The successful applicant will have an unique opportunity to enjoy the facilities of the Molecular Endocrinology laboratory of the Tenovus Institute and the above named departments of the University of Leicester and gain extensive experience in technologies related to steroid-hormone mechanisms, protein-DNA interactions and cloning and analysis of genes.

Applications in the form a curriculum vitae with the names and addresses of two referees to **Dr Peter Davies, Tenovus Institute for Cancer Research, Heath Park, Cardiff** from whom further information is available. (8274)H

AWARDS

NUFFIELD FOUNDATION

Awards to Newly Appointed Science Lecturers in Science, Applied Science and Engineering

The Trustees of the Nuffield Foundation are offering a limited number of awards of up to £4,000 to newly appointed University and Polytechnic lecturers in Science, Applied Science and Engineering.

The object of the awards is to give assistance to such lecturers in the early stages of their independent research careers.

Awards will be made competitively and preference will be given to lecturers wishing to explore novel and original lines of research that may not yet be at a stage suitable for Research Council support. Sixty awards were made in 1988.

ELIGIBILITY

Applicants must be newly appointed to lectureships or equivalent posts in Science, Applied Science, Mathematics, Engineering or Medical Departments. Candidates must apply within 12 months of taking up their posts and may apply between the time of being appointed and taking up the post.

HOW TO APPLY

There are two selection meetings a year. The next closing date for applications is 31st March 1989. Applications must be on the appropriate form, which is available from the **Nuffield Foundation, 28 Bedford Square, London WC1B 3EG.**

The scheme is only open to applicants from institutions within the United Kingdom. (8262)N

MOUNT ST. MARY'S COLLEGE
SPINKHILL
SHEFFIELD

POST GRADUATE AWARD

An award of not less than £2,000 per annum for two years is available for former pupils of the College who are in need of support for a Post Graduate course at a U.K. University.
Forms of application are available from the Clerk to the Trustees, 5 Porlock Grove, Trentham, Stoke-on-Trent ST4 8TN. (8320)N

ASSISTANTSHIPS continued

BIRKBECK COLLEGE
(University of London)

POSTDOCTORAL RESEARCH ASSISTAN

DEPARTMENT OF CRYSTALLOGRAPHY

Applications are invited for a postdoctoral research assistantship fun by the SERC for 3 years. The project involves the modelling of prot solvent and protein-in-protein interactions using state of the art elec static models. An essential part of this project will involve the Resea Assistant collaborating with Dr. S. Price in the Theoretical Chemis Department, Cambridge as well as with Dr. J. M. Goodfellow and Dr. J. Thornton at Birkbeck. Experience in computational techniques with a ba ground in a physical or chemical science would be an advantage. Sal will be within range £11515–£13330 p.a. inclusive of London Weighting Applications in duplicate including a full curriculum vitae and names a addresses of 2 referees should be sent to the **Assistant Secretary (Pers nel), Birkbeck College, Malet Street, London, WC1E 7HX.**

Further details can be obtained from Dr. Goodfellow on 01-631 6368. (8315)I

SEMINARS & SYMPOSIA

LEUKAEMIA RESEARCH FUND

International Research Symposium on "PRELEUKAEMIA"
at the Royal College of Physicians, London NW1
on Monday 13th March 1989

Registration fee (including lunch) £15
For programme details and registration form apply to:
LEUKAEMIA RESEARCH FUND, 43 Great Ormond Street, London WC1N 3JJ (tel: 01-405 0101) (8316)M

Third Forefront Symposium of the International Society of Nephrolog

"Organization of membrane polarity in epithelial cells
July 2 to July 6, 1989, Arolla, Switzerland

The general topic is "Organization of Membrar Polarity in Epithelial Cells". Subjects to be considere include differentation and extracellular matrix, polar zation of epithelial cells, biogenesis of membrar proteins, structure and function of transport protein housekeeping functions of epithelial cells and regul tion of epithelial cell functions.

Invited speakers and chairmen:
Q. Al Awqati; A. Aronson; D. Ausiello; D. Benos; M Burg; M. Caplan; B. Cunningham; A. Doucet; I Ekblom; D. Fambrough; H. Garty; G. Giebisch; M Gottesman; S. Gluck; H. W. Harris; J. D. Horisberge T. MSc/Diploma in Neuroscience
Department of Preclinical Veterinary Sciences
University of Edinburgh

The above internationally recognised Department together with Departments in the Faculty of Medicine offers a one year MSc in Neuroscience. The course is practically based and is by examination and dissertation. There is instruction on modern anatomical and physiological techniques used in Neuroscience. The techniques include intracellular and extra-cellular recording, voltage-clamp, patch-clamp and receptor binding. A five week clinical module is now included and covers Dementia, Brain Tumours and Depression.

Suitable applicants would include Honours Science students wishing to convert to Neuroscience or graduates of Medicine, Dentistry and Veterinary Science. A limited number of studentships are available.

Further details may be obtained by contacting **Dr R J Martin, Dept. of Preclinical Veterinary Science, R(D)VS, Summerhall, University of Edinburgh, Edinburgh EH9 1QH. Tel. 031 667 1011 Ext. 5344.** (8260)C

WACIID '89

Winter Advanced Course for Immunology and Infectious Diseases '89

NAGARA FURUSATO VILLAGE, CHIBA PREFECTURE, JAPAN
5th - 8th February, 1989

Organizing Chairman: Tomio Tada

Sponsored by:
Japan International Friendship and Welfare Foundation

This Course, the first in a series to be held in Japan, will bring together internationally-recognized experts in the fields of Immunology and Infectious Diseases, as well as students actively engaged in research.

The program includes lectures, informal discussions and posters, as well as social and sports activities.

Invited speakers include:

Drs. F Alt (U.S.A.)
M Davis (U.S.A.)
S Habu (Japan)
Len Herzenberg (U.S.A.)
Lee Herzenberg (U.S.A.)
N A Mitchison (England)
K Rajewsky (F.R.G.)
A. Singer (U.S.A.)
T Tada (Japan)
M Taniguchi (Japan)
T Tokunaga (Japan)
and
M Cooper (U.S.A.)
H Grey (U.S.A.)
D. Littman (U.S.A.)
T Kishimoto (Japan)

Conference on

TRANSLATIONAL CONTROL

September 13-17, 1989

Organized by:

Dr. Michael B. Mathews, *Cold Spring Harbor Laboratory*
Dr. Nahum Sonenberg, *McGill University*

Topics for discussion will include:

- *growth and development* • *mRNP*
- *metabolic effects* • *heat shock* • *interferon*
- *animal, plant, procaryotic and viral systems*
- *mRNA structure* • *mRNA stability*
- *ribosome frameshifting* • *SRP*
- *convalent modifications of translation factors*
- *translation factor genes and their expression*

Supported by a grant from ICN Biomedicals, Inc.

Registration and abstract materials are available from:

Meetings Coordinator
COLD SPRING HARBOR LABORATORY
P.O. Box 100
Cold Spring Harbor N.Y. 11724

INTERNATIONAL SYMPOSIUM ON SIGNAL, PERCEPTION AND TRANSDUCTION IN HIGHER PLANTS

NATO ADVANCED RESEARCH WORKSHOP TOULOUSE, FRANCE, 9-13th JULY 1989

The workshop will examine the most recent available data on molecular mechanisms involved in the response of plant cells to different biotic and abiotic stimuli.

Topics to be covered include:
Stimulus-response coupling mechanisms — Plant membrane receptors — Second messengers in plant — Message transducers in plants — Specific signalling devices in plants — New approaches based on DNA recombinant technology.

The workshop will consist of lectures, discussion and poster sessions. There is a limited member of NATO bursaries to assist post-graduate students from NATO countries and especially from Greece, Portugal and Turkey.

Details and applications (with a C.V.) to:

Dr. Raoul RANJEVA (Workshop Director)
Centre de Physiologie Végétale

Deadline: 01/03/89

Organizing Committee: R. RANJEVA (Director, Toulouse); A.M. BOUDET (co-director, Toulouse); J. MORRE (USA); A. SIEVERS (FRG); A.J. TREWAVAS (UK). (W5828)M

ROYAL SOCIETY DISCUSSION MEETINGS
APRIL 1989

5 and 6 April: 'THE DEEP-SEA BED: ITS PHYSICS, CHEMISTRY AND BIOLOGY' organized by Professor H. Charnock, F.R.S., Professor J.M. Edmond, F.R.S., Professor I. McCave, Dr A.L. Rice and Dr T.R.S. Wilson.
Speakers: K.J. Richards, I.N. McCave, M. Angel, S. Emerson, T.R.S. Wilson, R.C. Aller, M. Rutgers van der Loeff, P.A. Jumars, A.R.M. Nowell, A. Gooday, R.J. Parkes, E.T. Sunquist, T.P. Gross and S.A. Thorpe.

26 and 27 April: 'GROWTH FACTORS IN DIFFERENTIATION AND DEVELOPMENT' organized by Dr M.J. Crumpton, F.R.S. and Professor T.M. Dexter.
Speakers: G.B. Pierce, J.M.W. Slack, T.M. Dexter, D. Metcalf, F.R.S., J.J.T. Owen, F.R.S., T. Honjo, M. Noble, A.B. Roberts, R. Ross, M. Bernfield, W.J. Leonard, R.H. Michell, F.R.S., M.J. Crumpton, F.R.S. and E. Rozengurt.

Registration details (no fee for attendance): The Scientific Meetings Secretary (ref. DMN/CAJ), The Royal Society, 6 Carlton House Terrace, London SW1Y 5AG (Tel: 01-839 5561, ext. 278. Telex: 917876). (8304)M

IMPERIAL CANCER RESEARCH FUND DNA TUMOUR VIRUS MEETING 1989

The Imperial Cancer Research Fund is sponsoring a meeting on DNA Tumour Viruses to be held in Churchill College, Cambridge, England from *24th to 29th July, 1989* (5 days). The subject of meeting will be the molecular biology of small DNA tumour viruses, particularly polyoma virus, SV40 and adenoviruses. It will replace for this year the annual Cold Spring Harbor DNA tumour virus meeting.

The meeting is open to all interested research workers. The scientific programme will include oral presentations and posters. The cost for registration, accommodation, food and the abstract book will be £260.

Anyone interested in attending the meeting should apply immediately for further details to: **Mrs. Clare Middlemiss, ICRF DNA Tumour Virus Meeting Secretary, Imperial Cancer Research Fund, Lincoln's Inn Fields, London WC2A 3PX, England.** (8124)M

Sequencing With TAQ DNA Polymerase

Stratagene's new ThermalBase™ DNA Sequencing Kit utilizes the thermostable DNA polymerase of thermus aquaticus (Taq polymerase). There are numerous advantages to sequencing with Taq polymerase.

Reduced Artifacts
The reactions are carried out at 70°C, substantially reducing DNA secondary structure artifacts commonly seen with the Klenow fragment of *E.coli* DNA polymerase, reverse transcriptase, or modified T7 DNA polymerase (Sequenase*).

Specific Primer Binding
The higher temperature also creates more stringent conditions for primer binding. Thus false priming is far less likely to occur at sites of imperfect hybridization.

The ThermalBase™ Sequencing Kit protocol is as simple as sequencing with the Klenow fragment or Sequenase*. Uniform labeling can be achieved with ^{32}P or ^{35}S nucleotides or oligonucleotide primers (including ^{32}P, ^{35}S, or fluorescent primers for automated systems). Single stranded or double stranded (boiling miniprep) DNA templates may be used.

*Sequenase is a trademark of United States Biochemical Corp.

Dr. Maryann Zounes of Syntro Corporation has independently compared Stratagene's Taq Polymerase with Sequenase* (modified T7 DNA polymerase) and a competitor's Taq polymerase. Double stranded supercoiled DNA was prepared using the boiling miniprep procedure. Sequenase* reactions were performed according to the manufacturer's instructions.

Arrows highlight Sequencing artifacts.

The accompanying figure illustrates the ability of Stratagene's Taq polymerase to sequence a double stranded DNA region in which Sequenase* and a competitor's Taq polymerase generate multiple artifacts (arrows). Stratagene's Taq polymerase proceeds through these regions with little difficulty. Overall, Taq polymerase provides substantially more information in artifact-prone regions than either the Klenow fragment or Sequenase*.

11TH INTERNATIONAL CONGRESS OF THE INTERNATIONAL SOCIETY OF DEVELOPMENTAL BIOLOGISTS 20TH-25TH AUGUST 1989

JAARBEURS CONGRESS BUILDING
UTRECHT THE NETHERLANDS

YOUR OPPORTUNITY TO REVIEW ADVANCES IN THE FIELDS OF HUMAN, ANIMAL AND PLANT DEVELOPMENT

Developmental biology is a rapidly advancing science which enjoys increasing attention from a wide range of associated disciplines. The programme for this major scientific event will place emphasis on assessments in a wide variety of disciplines, including molecular biology, cell biology, biochemistry, embryology, genetics, immunology, botany, oncology and biotechnology. Plenary lectures, parallel symposia, poster contributions and special social events will combine to make the congress an international success.

Chairpersons		Symposia topics include:
R.G. Edwards	Cambridge	In vitro fertilisation and embryo transplantation
W.J. Gehring	Basel	Genetic control of pattern formation
Th. Graf	Heidelberg	Haemopoietic stem cell differentiation
J.B. Gurdon	Cambridge	Embryonic induction
J.K. Heath	Oxford	Growth factors and their receptors
M. Johnson	Cambridge	Cytoplasmic organisation and development
G. Klein	Stockholm	Developmental tumors
N. LeDouarin	Nogent-sur-Marne	Developmental neurobiology
A. McLaren	London	Germ cells
F. Melchers	Basel	Developmental immunology
H. Mohr	Freiburg	Developmental botany
G.B. Pierce	Denver	Teratocarcinoma and early mammalian development
J. Rossant.	Toronto	Cell lineage in early embryogenesis
H.C. Schaller	Heidelberg	Pattern formation in invertebrates and lower eukaryotes
J. Sedat	San Francisco	Nuclear organisation and gene expression
A. Surani	Cambridge	Genomic imprinting and early development
J.P. Thiery	Paris	Extra-cellular matrix and cell adhesion molecules
M.Van Montagu	Ghent	Molecular development of plants
I.M. Verma	San Diego	Signal transduction and transcriptional regulation
E. Wagner	Heidelberg	Gene transfer into stem cells and embryos

International Exhibition: the publishers of *Nature* will be organising an associated international exhibition.

Satellite meetings: "Early amphibian development", contact person A.J. Durston
"Pathobiology of human germ cell tumors", organisers I. Damjanov, J.W. Oosterhuis, H. Walt
"Microgravity as a tool in developmental biology" organiser G.A. Ubbels.

DATING OF THE TURIN SHROUD

SCIENTIFIC SOFTWARE REVIEW

70% mutants using phage or new phagemid* vectors

Now, there are *two* Muta-Gene™ *in vitro* mutagenesis kits. Both are based on a highly efficient and simple method of site-specific *in vitro* mutagenesis. This unique method[1,2,3] uses a simple, biological means of selecting against the original non-mutated template and results in highly efficient mutagenesis.

These kits offer you:

- **Versatility.** Clone into M13 vectors and use the **Muta-Gene M13 kit.** Or clone into pTZ phagemid vectors and use the **New Muta-Gene phagemid kit.** Gain the advantages of plasmids, such as cloning large inserts, and still obtain single-stranded DNA phages for mutagenesis and sequencing.
- **High mutation efficiency.** Greater than 70%.
- **Ease-of-use.** Only two enzymes are required. Pretested reagents and a detailed instruction manual insure success.
- **Rapid results.** Minimal manipulation means you get your mutants fast.
- **Controls.** Control DNAs, oligonucleotide primers, and phage or phagemid are included to test the system.
- **Economical.** The kits contain reagents for 25 reactions. Compare prices before you buy.

For more information, contact your Bio-Rad representative. In the U.S., call Bio-Rad's Molecular Biology Technical Services at 1-800-424-6783 and request Bulletin 1409. Or circle the reader service number.

*These phagemids were constructed from pUC18/19 by inserting the origin of replication.[4] Under most circumstances, they replicate as plasmids. Super infection with a helper phage results in phage-like particles containing single-stranded phagemid DNA.

Answers.

Now get peptides for less than others charge for one!

Recent proprietary techniques and new optimized synthesis methodologies enable MPS to supply you with all the custom peptides you need at a fraction of the cost and time of others.

AFFORDABLE—We offer peptides at ¼ of the price others expect you to pay!

AVAILABILITY—We can supply you with 100 completely different 15-residue peptides in 3 weeks!

QUALITY—Our peptides are of the highest quality available anywhere!

With MPS as your partner, quality, price, and availability will never again be limiting factors in your research. We'll help you make your research visions become realities!

We can provide you with:

- HIV related peptides
- Magainin peptides
- ^{3}H labeled Magainin peptides
- Neurologically active peptides
- Biologically active peptides
- Isotopically labeled peptides (^{15}N, ^{13}C, D)
- ^{3}H labeled peptides

MPS also offers:

Custom HF Cleavage Service and the state-of-the-art HF Cleavage System.

COMPARE OUR PRICES

MPS is offering custom peptides at the extraordinary prices listed below.

10mer	$400
15mer	$550
20mer	$800

Prices are based on 50mg of HF Cleaved Peptide, 4 to 6 weeks delivery, minimum order of 3 peptides or $1000.

CAN YOU OBTAIN PEPTIDES FOR LESS?

Compare our service with the custom synthesis services of Applied Biosystems, Bachem, Cambridge Research Biochemicals, and Peninsula Labs.

Before you buy an automated peptide synthesizer (*machinus peptisauros**), you should also consider the actual cost for in-house synthesis which includes the cost of reagents, personnel, service contracts, analysis, waste disposal, downtime and, of course, the initial cost of the synthesizer.

***machinus peptisauros** (ma • shēn • us pep'ti • sar • ōs'), n. voracious laboratory inhabitant known for its unceasing appetite for endangered research funds; cantankerous, but if fed and cared for with great devotion will generate peptidus minimus.

"Top Rated Statistics Package"
INFOWORLD, September 19, 1988

Systat. Because other statistics and graphics packages are not enough.

Systat now offers more statistical graphics than any other PC or mainframe package. And we still give you less bulk with more statistics.

Statistics Basic statistics, frequencies, t-tests, post-hoc tests Multiway crosstabs with log-linear modeling, association coefficients, PRE statistics, Mantel-Haenszel, asymptotic standard errors Nonparametric statistics (sign, Runs, Wilcoxon, Kruskal-Wallis, Friedman two-way ANOVA, Mann-Whitney U, Kolmogorov-Smirnov, Lilliefors, Kendall coefficient of concordance) Pairwise/listwise missing value correlation, SSCP, covariance, Spearman, Gamma, Kendall Tau, Euclidean distances, binary similarities Linear, polynomial, multiple, stepwise, weighted regression with extended diagnostics Multivariate general linear model includes multi-way ANOVA, ANOCOVA, MANOVA, repeated measures, canonical correlation Principal components, factor analysis, rotations, components scores Multidimensional scaling Multiple and canonical discriminant analysis, Bayesian classification Cluster analysis (hierarchical, single, average, complete, median, centroid linkage, k-means, cases, variables Time series (smoothers, exponential smoothing, seasonal and nonseasonal ARIMA, ACF, PACF, CCF, transformations, Fourier analysis Nonlinear estimation (nonlinear regression, maximum likelihood estimation, and more).

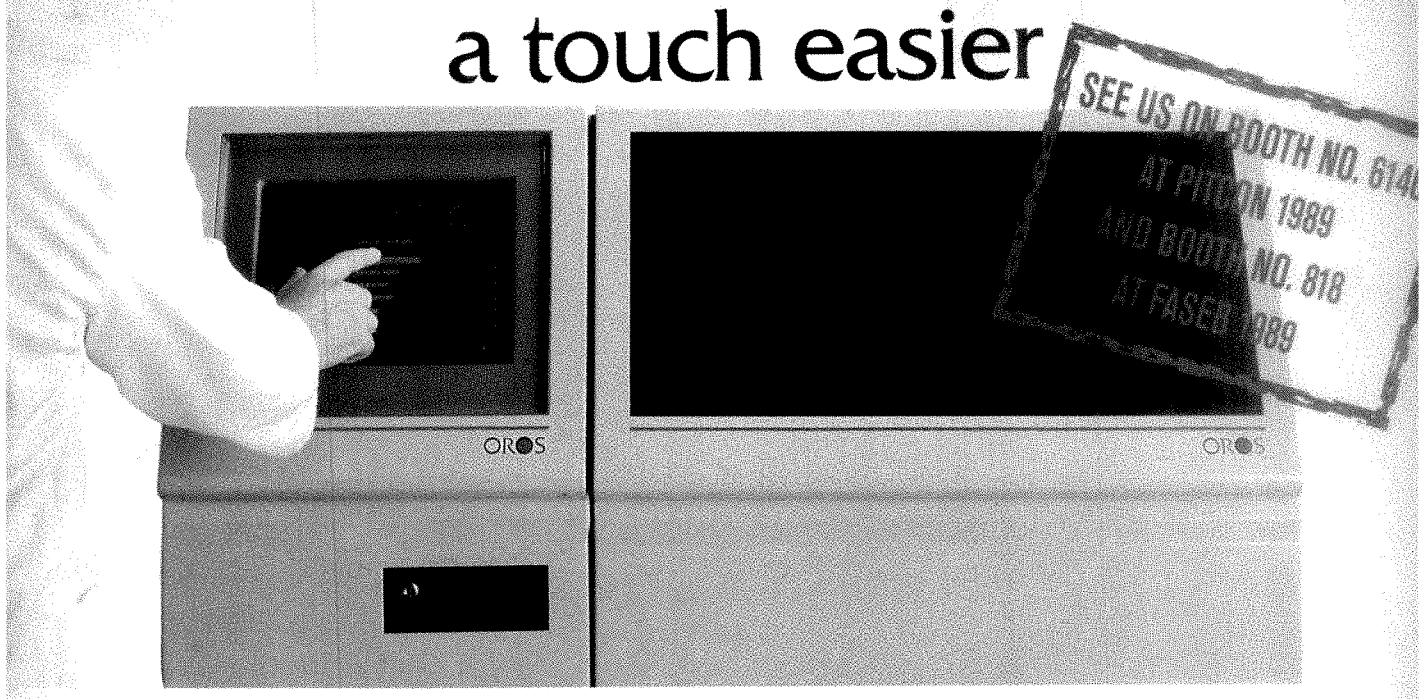
Graphics Overlay plots Drivers for most graphics devices *Two dimensional:* Error Bars Scatterplots Line and Vector Graphs Vector, Dot, Bubble and Quantile Plots Bar Graphs (single, multiple, stacked, range) Box plots (single and grouped) Stem-and-leaf diagrams Linear, quadratic, step, spline, polynomial, LOWESS, exponential smoothing Confidence Intervals and ellipsoids (any alpha value) Smooth mathematical functions Rectangular or polar coordinates Log and power scales ANOVA interaction plots Histograms (regular, cumulative, fuzzy) Stripe and jitter plots Gaussian histogram smoothing Scatterplot matrices Voronoi Tesselations Minimum spanning tree Maps with geographic projections (U.S. state boundary file included) Chernoff faces Star plots Fourier plots Pie charts Contour plots on regularly and irregularly spaced points Control charts and limits *Three dimensional:* Data plots Smooth function plots Vector plots Linear, quadratic, spline, least squares surface smoothing Three-dimensional type fonts.

Data Management Import/export Lotus, dBase, and DIF files Full screen data editor Full screen text editor Unlimited cases Missing data, arrays, character variables Process hierarchical, rectangular or triangular files, irregular length records Character, numeric, and nested sorts Merge and append large files Unlimited numeric and character variable transformations Subgroup processing with SELECT and BY Value labels and RECODE Statements Macro processor with programming language, screen control, file manipulation, applications generation, and report writing.

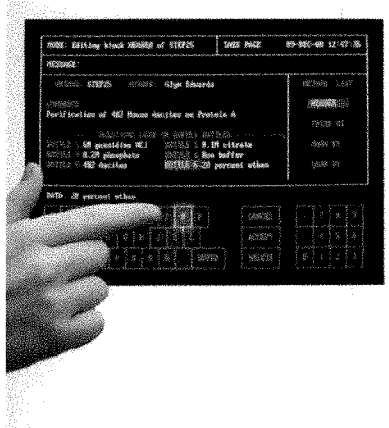
SYSTAT™

1st in *PC WEEK* User Satisfaction

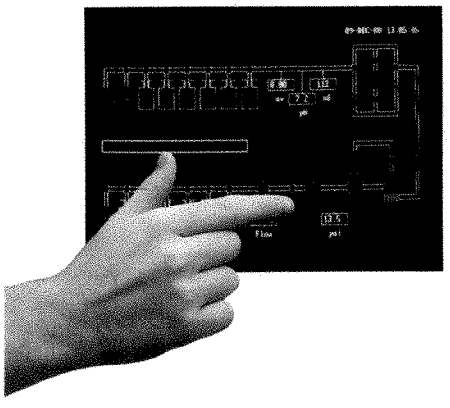
December 5,



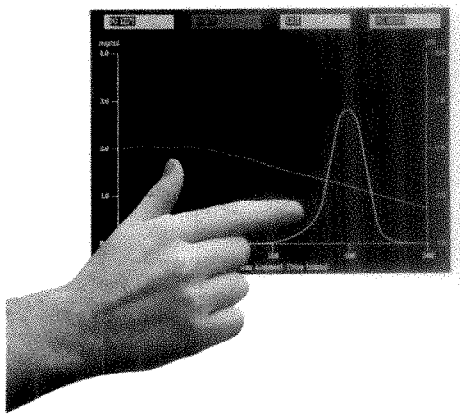
Systat operates on IBM PCs and compatibles, MS-DOS and CP/M machines, several UNIX minicomputers, and the VAX/Microvax. Menu/windowed Macintosh version also available. Single copy price $795 USA and Canada, $895 Foreign. Site licenses, quantity prices and training seminars available. No fees for technical support. Statistics and graphics available separately.



For more information, call 312 864.5670 or write Systat Inc., 1800 Sherman Avenue, Evanston, IL 60201.



The following are registered trademarks: CP/M of Digital Research, Inc., IBM PC of IBM, Inc., MS-DOS of Microsoft, Inc., Macintosh of Apple Computer Inc., UNIX of AT&T and VAX of Digital Equipment Corporation.



Systat. Intelligent software.

We've made protein purification a touch easier

Introducing MultiLab, a flexible protein purification system which you control with the touch of a finger.

All you have to do is specify the method using the touch sensitive screen and MultiLab's expert software will monitor and control all the parameters for you.

MultiLab has been designed for...

- methods development
- protein purification
- monoclonal antibody purification
- evaluating column materials

MultiLab runs at low and medium pressures, enabling you to develop methods with the same materials that you can use on a larger scale.

MultiLab's safety features include air sensors to detect the absence of buffers and an air eliminator to protect the column, so you don't have to be present while MultiLab gets on with the job.

For more information on how MultiLab can make protein purification easier for you call OROS now.

THIS WEEK

A pulsar is born

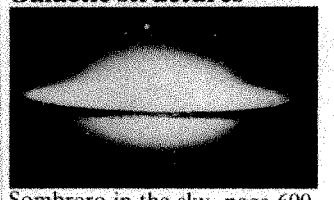
The pulsar now uncovered in the remains of supernova 1987A is not at all what was expected. It's spinning twice a millisecond, is apparently in a close 8-hour orbit with an unknown companion, and is underluminous for its rotation rate. All these pose theoretical difficulties. Page 595.

AIDS inhibitors

The crystal structure of HIV-1 protease confirms its relationship to cellular aspartyl proteases and should facilitate the design of inhibitors for use in AIDS therapy, pages 615 and 596.

Climate carbonates

Carbonate deposition is one factor that affects climate and atmospheric carbon dioxide concentration. A model for the dependence that distinguishes



shallow-water and ocean-water carbonate deposition, described on page 637, suggests that it is the presence of plankton in the open ocean that has prevented continued glacial conditions on the Earth.

Extinction event

A period of diversification of the plankton of the Latest Proterozoic (about 600 million years ago) was followed by an extinction event at the Proterozoic/Cambrian boundary, pages 642 and 602.

Galactic structures

Sombrero in the sky, page 600. Here in the Solar System, the Earth has a 'ring', page 629.

Eruptions and implosions

The rare event of an earthquake occurring by implosion, rather than by sliding, is investigated further along the plate boundary in Iceland, recent site of such earthquakes, page 640. A massive volcanic eruption, larger than the devastating Lakigigur eruption of 1783, seems to have occurred on the Pacific sea floor in the 1960s. The 15 km^3 of erupted lava has only now been observed by sonar, leading to an eruption of new ideas, page 603.

Organelle assembly

A constitutive heat-shock protein, hsp60, is necessary for the correct assembly of multi-subunit mitochondrial enzymes in yeast (page 620), supporting the concept of protein-catalysed assembly of proteins entering the mitochondrial matrix.

Regulatory mechanism?

Two types of thyroid receptor protein are synthesized by alternative splicing from the rat *erbA*α gene; one of them does not bind thyroid hormone and inhibits the hormone-dependent action of the other *in vitro*, page 659.

It always helps to get an early warning.

TPA helps in the early detection of recurrent carcinomas. And early treatment can improve the prognosis and quality of life for your patient.

Rises in the post-treatment levels of serum TPA often precede the clinical symptoms of recurrent carcinomas by as much as six months.*

Serum TPA (Tissue Polypeptide Antigen) can be measured quickly and easily using the Prolifigen® TPA IRMA test.

*Documented for carcinomas of the bladder, breast, lung and genital tract.

The illustration depicts the little Dutch boy Hans Brinker saving his home-town of Haarlem from flooding by sticking his finger into a hole in the dyke. The story was written by Mary Mapes Dodge in 1873.

This legend about the fair-haired hero of Haarlem is one of the world's best known. As with all good fairy-tales, it has a moral: "Don't wait until too late."

Serum TPA measurements: For early and efficient detection of recurrent malignant disease.

DNA PROBES

(From the people who gave you Designer Genes™)

Human Interleukin 1∝

IL-1∝ is one of the two major forms of IL-1 identified. Probes are available for Exon 5, 6 and 7 of the IL-1∝ gene.

Human Interleukin 1ß

The other major form of IL-1. Probes are available for Exon 5, 6 and 7 of the interleukin 1ß gene.

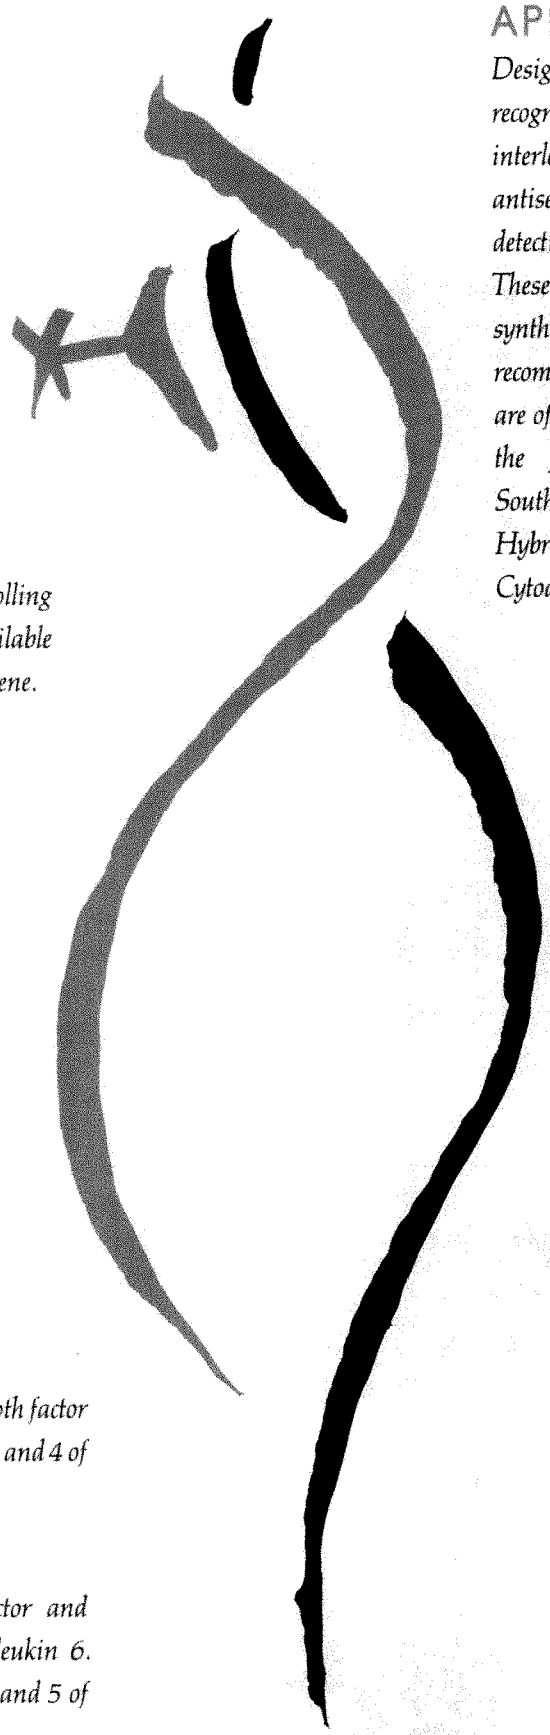
Human Interleukin 2

Interleukin 2 is a central factor controlling proliferation of T cells. Probes are available for Exon 1, 2, 3 and 4 of the IL-2 gene.

Human Interleukin 3

IL-3 is a growth and differentiation factor for multipotent erythroid and myeloid precursors. Probes are available for Exon 1, 2, 3 and 5 of the IL-3 gene.

Human Interleukin 4



With exon boundaries not yet fully defined for the IL-4 gene, probes have been designed for the 3′ region, mid-region and 5′ region of the IL-4 gene.

Human Interleukin 5

Interleukin 5 is identical to B cell growth factor II. Probes are available for Exon 1, 2, 3 and 4 of the IL-5 gene.

Human Interleukin 6

Interferonß$_2$, hybridoma growth factor and BSF-2 are now known to be interleukin 6. Probes are available for Exon 2, 3, 4 and 5 of the IL-6 gene.

APPLICATIONS

Designer Probes™ from British Bio-technology recognise certain unique exons of genes coding for interleukins. As the probes are based on the antisense sequence they are also suitable for detecting the corresponding regions in mRNA. These probes are single-stranded, chemically synthesized and supplied ready purified with recommended protocols for labelling. The probes are of defined length and Tm and are suitable for the following applications. •Northern and Southern Hybridisation •Colony & Plaque Hybridisation •In situ Hybridisation •Dot-blot & Cytodot Hybridisation.

PROBE COCKTAILS

Exon specific Designer Probes™ allow the identification of particular gene regions. The exons selected are all contained in the region coding for the mature forms of the proteins. Also available are Probe Cocktails which consist of an equimolar mixture of exon specific probes. Probe Cocktails will pick up a combination of different regions of the gene and therefore show a higher level of sensitivity than individual probes. Probe Cocktails can be used for all the applications listed above.

Reviews on IMMUNOASSAY TECHNOLOGY

Edited by S. B. Pal

Immunoassay techniques are continually being developed and refined, and applied in a broader range of uses. The books in this series comprise review articles and descriptions of methods of immunoassay, which are not reliant on radioisotopes, and reflect the growing importance of immunoassay technologies.

Managing references just got easier.

Stop filing index cards and misplacing references! Organize them instead, with a specially designed database pro-gram called Pro-Cite®. Pro-Cite makes it easy to manage references. Now you can sort, search, or index references from journal articles, books, or any other source. Keep references organized, include long abstracts or notes, and format bibliographies in any style.

Pro-Cite puts references in order.

Call (313) 996-1580 today. Pro-Cite is available for IBM® PCs and the Macintosh® and the programs are data compatible. Other PBS products include Biblio-Links™ (companion programs that transfer records into Pro-Cite) and Pro-Search™ (a specialized communications program for searching BRS and DIALOG (IBM only)). Pro-Cite is now NOT copy protected.

WHERE CAN YOU GET TH
COMPETE IN AgBIOTECH

- **The significant research**
- **The newest methods**
- **The latest products**
- **The notable experts**
- **The industry contacts**
- **The financial synergy**
- **The international perspective**

AgBIOTECH '89 features a multi-track professional seminar program that only the editors of BIO/TECHNOLOGY could produce. And it's *all-ag*, all aspects — from lab to production to marketing to regulation.

Science/Technical

You'll hear leading researchers responsible for the most significant and splendid advances in transgenic crops and genetic engineering techniques discuss their research.

Business/Regulatory

You'll hear experienced industry executives with in-the-trenches experience discuss what has worked, what is economically viable, regulation, patenting, and future development.

If you're in ag-biotech — and determined to stay competitive in the '90's — you can't afford to miss this stimulating program! REGISTER TODAY!

Free Exhibitor Workshops

Exhibitors having new scientific data, new applications, new products, or new capabilities of established products, will be holding special exhibitor workshops — *at times that do not conflict with the scheduled seminars.* Admission FREE to all attendees.

Exhibitor Sponsors:

Evans BioControl, Inc.
Oregon Freeze Dry
Nova Pharmaceutical Corporation
North Carolina Biotechnology Center
B. Braun Biotech

Sponsorship/Management

AgBIOTECH '89 is sponsored by *BIO/TECHNOLOGY, the International Monthly for Industrial Biology,* the leading publication in the field and a consistent showplace of the best and the latest in agricultural biotechnology. It is managed by Conference Management Corporation, a leader in professional conference and trade show management.

Hands-On Exhibit Hall

Designed as the industry's most exciting showcase, AgBIOTECH '89 will once again feature exhibits of the very latest in products, equipment, services and resources that the leading suppliers have to offer. You'll be able to see, test, and compare the leading-edge lab equipment and commercial ag-biotech products.

Exhibit Hall Hours

Tuesday, March 28 —
11 a.m. to 5 p.m.

Wednesday, March 29 —
11 a.m. to 5 p.m.

Thursday, March 30 —
11 a.m. to 3 p.m.

There's nothing hard about our software.

System Gold,™ the Personal™ Chromatograph, teams an advanced HPLC system with a powerful personal computer* to make balancing many LC functions a lot easier.

The software is what makes it so easy. A mouse, drop down menus, truly helpful help screens and enhanced graphics give you the easiest control of your data ever.

All System Gold LC modules are fully programmable, and linked on a bi-directional digital network. So you control and monitor the entire system from a single point.

Superior integration algorithms always give you accurate, reproducible results. Stunning post-run graphics make data comparison and spectral analysis especially easy. Because of multi-tasking, you can even review data while the system is doing another run.

And it's easy to configure System Gold for any application — methods development, QC, analysis of amino acids, proteins, peptides and more.

Contact your Beckman HPLC Representative at 800/742-2345. Or Beckman Instruments, Inc., Altex Division, 2350 Camino Ramon, P.O. Box 5101, San Ramon, CA 94583. Offices in major cities worldwide.

There's nothing hard about it.

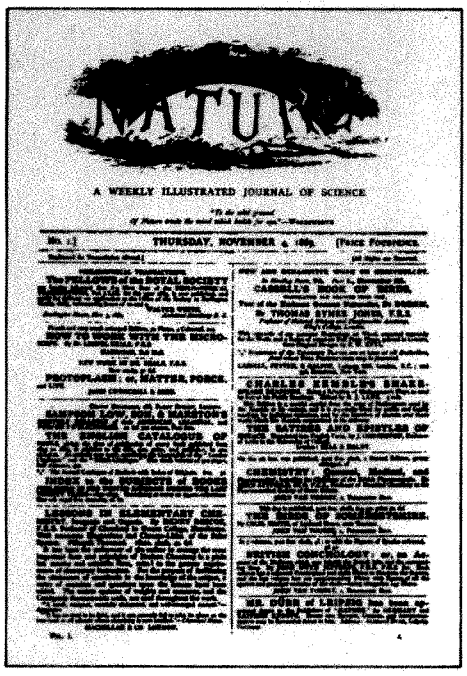
Perfection

An egg – one of the marvels of nature. Perfect in its structure and function.
Carl Zeiss also strives for perfection with its new series of electron microscopes. The optimum combination of world-renowned optics, precision mechanics and electronics for the highest possible performance.
Applications-oriented innovation and a systematic approach to design and construction – from the smallest microcomponent to the most complex assembly – result in research instruments of superb quality. These state-of-the-art microscopes from Carl Zeiss give all researchers the opportunity to achieve outstanding results, including new levels of image quality and fast, accurate elemental analyses.

Sales and service worldwide: more than 140 offices around the world to serve the electron microscopist

Perfection Through Innovation
Zeiss Electron Microscopes



CEM 902, the innovative, energy-filtering transmission electron microscope with integrated image analysis – for outstanding imaging and efficient elemental analyses.

Making budgets in a straitjacket

The new US president has signalled how he would have spent money if there were more of it, and has singled out public education. The academic community should see that the message is amplified.

PRESIDENT George Bush's heart is in the right place, but his pockets are filled with lead. That is the first conclusion about the new US presidency to be drawn from the extraordinary occasion last week when the new incumbent, with beginner's bustle, rolled together the traditional State of the Union Address with the much-awaited explanation of how his budget will differ from that submitted by his predecessor to the US Congress just a few weeks ago (see *Nature* **337**, 104 & 200; 1989). Bush said all, or nearly all, the right things, but does not command the resources to make his wishes come true.

The new administration's difficulties have been plain for several months. To his credit, the new president did not hide from them last week. The formal constraint is so to manage planning for the next financial year (beginning on 1 October) that the statutory calculation in August of next year's deficit will come out at less than the $100,000 million allowed by the Gramm–Rudman rules.

The less calculable but more serious objective is to manage affairs so as not to disturb those elsewhere on whose willingness to continue lending to the United States depends the remarkable stability and growth of its economy. The new men at the White House have calculated that continued economic growth (an optimistic 4.5 per cent next year) will give them, in a year in which tax revenues increase above $1 million million for the first time, nearly $88,000 million extra to play with. No less than $64,000 million of that will be thrown into the expected spending gap, leaving a relatively small amount to meet extra inescapable costs. No wonder that the new president last week could make only token financial gestures towards the goals he has set himself for the four years ahead.

That does not mean that the goals are negligible. Under the rubric of US competitiveness, the Bush administration avows its support for science and technology (extending the tax credit on research and development spending by companies, affirming that the budget of the National Science Foundation must be twice that in 1988 by 1993 and even blessing the Superconducting Super Collider by name). Under the rubric of the "kinder and gentler society" which mocks the recollection of last year's bruising election campaign is a variety of environmental programmes that promise well (but will cost money only in future).

New programmes

The war on drugs is to be prosecuted with vigour, but again with real spending deferred. And the budget for next year includes a clutch of entirely novel spending programmes in support of public education in the United States which are to be judged by what they say about the president's intentions, not for what they will or even might accomplish.

While the US Congress may (and probably will) think differently, it will seem to many to be cruel that this brave talk should be heard when the US government is more constrained than ever by the lack of funds. Yet the truth is even more cruel than that. For the point seems to have been reached, in the brave history of the United States, when the future is constrained not simply by the gap between the US Treasury's spending and its disposable income, but by the gap between the ambitions of the United States as a whole and its disposable intellectual resources. For the state of public education in the United States, acknowledged for at least the past decade to be dreadful, should now be recognized as the most serious obstacle to the attainment of this and future new presidents' forgivably optimistic goals.

The circumstances are amply catalogued. The study of public education commissioned at the end of the Carter administration vividly drew attention to some of the more obvious problems — the difficulty of staffing engineering schools except by relying on graduate students from overseas, for example. By 1983, the Reagan administration's own contribution to the catalogue of neglect (called *A nation at risk*) declared that "a rising tide of mediocrity . . . threatens our very future". For a little while thereafter, several progressive states (which shoulder direct responsibility for education) made headway with schemes for improving the condition of elementary and secondary schooling, many of which persist. Yet the signs are that public education in the United States continues to deteriorate. Two years ago, a committee of the Carnegie Corporation under Dr Lewis Branscombe (then at IBM, now at Harvard) made the same point about the dependence of economic prosperity on the quality of young people's education, and chilled its audience with unflattering comparisons between the performance of children from the United States and elsewhere (in *A nation prepared*).

Promise of success

Since then, other more sombre truths have come to light — for example, the failure of 76 per cent of black students to graduate within six years from the universities they had begun to attend in 1980. It is no wonder that President Bush, like most candidates in last year's several election campaigns, is vowing again to fulfil the traditional promise of the United States that all newcomers, native-born or otherwise, will have an equal crack at success.

How well has he begun? The spattering of new programmes offered last week will not by themselves make much difference either way. Awarding prizes to successful schools and teachers may marginally encourage the others, while the plan to let each member of the Congress nominate a recipient of a $10,000 scholarship in science or mathematics will at least set senators and congressmen wondering about the causes that have thrust this patronage upon them. What matters more is that the new administration has declared its readiness to help stop the rot. Will the intellectual community in the United States be willing to seize the opportunity thus presented?

On the face of things, there is little that can be done. Public education, after all, is the responsibility of state governments, while one of the more obvious impediments to reform — the desperate shortage of able teachers — seems intractable unless all teachers are paid more, which would cost fortunes that no longer are easily manufactured. In any case, in the United States as elsewhere, academics working outside the elementary and secondary sectors of education have tasks of their own with which to grapple. The competition for research grants is as fierce as ever, but the administrators are now even more determined that overhead costs should be recovered. Yet like the US economy, US higher education rests on the now-shaky founda-

tion of elementary and secondary education. The all-too realistic fear in the United States that the economic competition with Japan (and even Europe) will eventually be lost stems from the acknowledged poverty of public education. Should not universities and other institutions of higher education recognize that their survival will even more literally turn on the future health of elementary and secondary education?

But what can research and higher education accomplish in such foreign fields? If it were that the problems of public education in the United States could be solved by spending money, it would probably be a better investment in the future to scrap the Superconducting Super Collider, or the extra shuttle flights, or even the National Science Foundation's doubled budget, for the sake of the improvement that those funds might buy. But money by itself is not sufficient. The more urgent needs are for a better understanding of how schools function well, for a school curriculum which is at once stimulating and improving, for a general appreciation of the particular importance of the most elementary education and for plain speaking about the seriousness of the difficulties created by the continuing impoverishment of the school system. Who but those in the academic community can do all these things? And how can they be neglected when it is as plain as at present in the United States that sufficient attention paid to public education would solve many of the other problems preoccupying the new president? □

Fraud on the agenda

The US Institute of Medicine recommends how malpractice in research should be controlled.

LAST week's report (see page 588) from the Institute of Medicine in the United States is one of the first by an academy or society representing a substantial part of the research community anywhere to face up to the problems of misconduct in the practice of research. That is not nearly as reprehensible as it may seem. Although the past decade has been peppered with lurid accounts of how apparently diligent researchers have pulled wool over the eyes of colleagues, either by the downright fabrication of data or by plagiarism, it is natural that leaders of the research profession should have been slow to respond.

Something akin to charity first prompts the belief that isolated scandals have been made conspicuous by contrast with the general practice, which is honourable. Then follows the proper fear that formal inquiry will engender the general opinion that research is shot through with malpractice. In the circumstances, the Institute of Medicine has been courageous in breaking new ground with its investigation. It is forgivable that its conclusions should be as tentative as they are.

The underlying difficulty is, of course, familiar — that there is no way of telling how common malpractice may be. Banks may hope to fix upper limits on the extent of embezzlement by careful accounting practice, for their losses on this account must always be less than the funds they cannot account for, but there is no arithmetical yardstick by which the total volume of scientific discovery is conserved. So may not the publicized cases of outright misconduct be simply the tip of a much larger iceberg? While there is no means by which the magnitude of the problem can be assessed, that suspicion cannot be flatly denied. What that, in turn, implies is that the damage done to the reputation of the research profession is certain to be much greater than is just. Researchers should not be too indignant on that score; even the most honest stockbrokers have been given a rough time because of the cases of insider trading brought to light in the past few years. The research profession naturally has an interest in regaining its reputation. A little reflection should show that its paymasters, usually governments, should be similarly inclined. How is that to be accomplished? Last week's report points to several ways which are none the worse for being obvious.

Universities should be more diligent and vigorous in their investigation of complaints or even suspicions, as should be grant-making institutions, while journals and professional societies also have their parts to play. Inevitably, the report muses on the incentives for misconduct and, concluding that competition in research and the pressure to publish are in part responsible, asks that something be done to blunt the edges of these pressures. Nothing much is new; the novelty is that it has been said by a respected but independent research academy. But the outcome is not a recipe for what should now be done.

Yet everybody working in research must know the answer. First, research is a profession whose integrity is, by definition, of astounding integrity; if it were otherwise, so that all published data and calculations were suspect, the notion that people can see further than others, in Newton's simile, by standing on the shoulders of others (giants or otherwise) would be falsified, and the scientific enterprise would long since have ground to a halt.

The torrent of discovery in the past few decades is in itself a proof of the integrity of the fabric of science. That is what nervous politicians must be made to understand. But, second, precisely because of the general appreciation of the integrity of the research profession, it is natural that people whose inclinations are less honourable should be attracted to it. In research, the problem is further magnified by unavoidable competition and by the circumstance that people are not required to behave well towards each other. Then, third, because discovery is the process of coming to grips with what people do not understand, mistakes are unavoidable and frequent — and cannot always be unambiguously distinguished from malpractice.

These sociological observations, however trite, have a bearing on the problem the Institute of Medicine (for one) would like to solve — that of minimizing the incidence of malpractice. The first conclusion must be that the incidence can never be absolutely zero, and that attempts to make it so can only bring science to a halt. Second, the people best placed to tell when observations have been improperly carried out or described are the close colleagues and competitors of the author or authors. That no doubt explains why committees of inquiry in this field have had such a poor track record in the past few years.

University departments or their equivalents in other kinds of organizations are better placed to sense when things have gone awry, and to take remedial action quickly. That they have been less effective than might have been expected in the past few years reflects two uncomfortable tendencies — the growing importance of the principal investigator as an autonomous unit in the conduct of research, and the dominance of his relationship with an external source of funds over that with more immediate and discerning colleagues. While principal investigators as such have not been conspicuous among malpractitioners — more often, it has been the hands they hired — putting back that clock completely would be impracticable, and probably unwise. But there is a case for arranging that principal investigators should more often than at present be less dependent on an external grant-making agency, and more dependent on their colleagues locally. At worst, good researchers who are not good managers might be helped to deal perceptively with their assistants.

The Institute of Medicine's report follows most other lines of argument than this. There should be more guidelines, university officials with special responsibility for "the responsible conduct of research", a special office at the National Institutes of Health (and presumably other agencies) to investigate complaints and even courses of instruction for beginners in research. In reality, there is at least as strong a case for believing that grant-making agencies should be less, not more, immediately involved: they should rather confine themselves to making sure that grant-recipients' institutions arrange that their funds are spent responsibly. And most grant-making institutions in the United States are too close to Congress, and too remote from where the action is, to function effectively and quickly in the prevention of misconduct. The best they can hope to do is to function judicially after the event, which is a heavy-handed business. □

British research learns how to spend extra

■ New interdisciplinary centres under way
■ Three-year increases in science budget

London

ONE of the most recent innovations in the British pattern of research support, the interdisciplinary research centre (IRC) is to be the subject of a major review after the British government has expressed caution about the programme. The review, which is to begin this month and be complete by the summer, will cover the selection of topics on which the centres work, their management, links with industry and their evaluation.

This development was announced with the publication last week of the annual advice from the Advisory Board for the Research Councils (ABRC) to the Department of Education and Science about the allocation of the science budget for the years ahead. The occasion is especially important this year because £340 million will be added to the science budget over the next three years.

For next year, the extra money amounts to £107 million, bringing the total for 1989–90 to £825 million. Of the extra, a quarter will be absorbed by extra allocations already made to the British Geological Survey, the British Antarctic Survey, CERN (the European High-Energy Physics Laboratory), directed research on AIDS and the cost of further redundancies at the Agricultural and Food Research Council (AFRC).

In previous years, prior allocations have absorbed most of the extra funds available, but in the coming year there will be a significant amount left over to be divided among the research councils. Overall, the 1989–90 budget for civil science is 11 per cent greater than in the present year, which ABRC says will do much to improve morale. But ABRC also says that the allocations for the succeeding 2 years imply a reduction of 3 per cent in real terms, which it says will mean that research councils will have to cut back on the projects they support.

With the extra funds available for next year, the Natural Environment Research Council (NERC) will spend £2.5 million on the first phase of an IRC in population biology at Imperial College, London, and £5.5 million on a centre for oceanography at Southampton. It will expand work on the biogeochemical ocean flux study (£2.7 million) and on the North Sea survey, meant to lead to a model for predicting water quality.

The Science and Engineering Research Council (SERC), the largest of those suporting natural science research, will spend £7 million next year on founding four new IRCs, in optical and laser-related science and technology, high-performance materials, polymer science and technology and process simulation, integration and control. It will also start a new programme in materials and biotechnology with £5 million of its extra allocation. SERC also has an extra £6 million for research grants, £9 million for university equipment and £0.4 million for its Cray computer facility.

The Medical Research Council (MRC) can now go ahead with an IRC in cell biology (£2 million) at Kings and University Colleges, London, in protein engineering (£2 million) at the University of Cambridge and the MRC Laboratory for Molecular Biology. It also has an extra £2.6 million for AIDS research and £2.3 million to set up an information and resource centre for mapping the human genome together with a related programme for research.

A further £2 million will allow the council to make a start on a national centre for clinical research at the Royal Postgraduate School at Hammersmith. There will again be more to spend on research grants (£1.5 million), studentships (£0.2 million) and equipment (£2.9 million).

The chief new projects of AFRC are an IRC in transgenic animal biology at the University of Edinburgh (£1.5 million) and new programme of research in plant molecular biology (£3.5 million), but the council will also take the lead in the government's new programme of research on agriculture and the environment (£1.5 million). The cost of restructuring the Institute for Animal Health is £3 million.

The delay in the announcement of this year's allocation of the science budget has fuelled speculation of a dispute between the prime minister, Mrs Margaret Thatcher, and the Department of Education and Science. The Labour party's education and science spokesman, Mr Jack Straw, says that the prime minister is unhappy with the department's adminstration of the councils, and that she wishes to move ABRC from beneath its umbrella.

But others suspect her of having intervened to contain spending on the IRCs, having advocated support for indivdual researchers of talent working singly or in small groups. But both the department and the Prime Minister's office deny there has been a dispute. The future of ABRC is itself being reviewed by the department; a report is due in the summer.

The UK science budget agreed for 1989–90 and planning figures for 1990–91 and 1991–92

Additions	1989–90 (£ million)	1990–91 (£ million)	1991–92 (£ million)
'Earmarked additions'	27	33	33
Research council restructuring	14	12	11
Interdisciplinary research centres	16	21	14
'Directed' programmes	23	29	34
Research grants	10	13	14
Manpower	3	5	8
Equipment	12	—	—
Other	3	4	2
Total	108	117	116
Final budget	825.6	837.6	855.8

Ozone limitations

Paris

FRENCH industry is taking steps to limit the use of products containing chlorofluorocarbons and halons. A series of conventions signed last week by representatives of government and industry are intended to reduce by 90 per cent the use of these propellants in aerosols by 1991 — two years before the target date set by the Montreal Protocol.

Beginning in 1991, aerosol cans containing chlorofluorocarbons will have to carry a written warning declaring that their use could affect the ozone layer. Manufacturers of refrigeration and air-conditioning appliances will encourage the recovery of coolants and will take measures to prevent leakage if appliances are dumped.

From the beginning of next year, manufacturers will also attach a warning to new appliances, encouraging users to collect the coolant for recycling. This will require the redesign of cooling circuits to include a drainage reservoir, as well as establishing public facilities for recovery of used coolant.

The newly signed conventions will also limit the use of fire-extinguishers containing halons. Atochem, the only French manufacturer of chlorofluorocarbons has agreed to make alternative compounds available to users.

NIH change procedures for monitoring scientific misconduct

Washington

STRUCTURAL changes are on the way in the procedures used by the National Institutes of Health (NIH) to monitor scientific misconduct. The impetus comes from a report released this week by the Institute of Medicine* (IOM) urging NIH to establish a new office to promote responsible research practices.

Although recent investigations have focused attention on misconduct in science, the IOM report looks instead at the broader question of what are appropriate standards for the conduct of research. It arises out of discussions on this issue between IOM and NIH held in 1985; a 17-member committee was appointed to write a report in 1987.

For the most part, the culture of science by its nature encourages proper conduct, says Arthur Rubenstein, chairman of medicine at the University of Chicago and chairman of the IOM committee. Tight budgets have put a variety of pressures on researchers, says Rubenstein. As well as encouraging a high rate of publication to substantiate high productivity, competition for scarce resources can tempt researchers to cut corners.

Rubenstein also cites the increasingly large size of laboratories, which makes it difficult for laboratory heads to fulfil their traditional role of monitoring the activities of their junior staff.

To combat these pressures, the IOM report suggests making explicit proper professional standards for research. Universities should set standards of conduct, provide formal instruction in research practices and create administrative positions carrying responsibility for conduct. Journal editors and professional societies are also asked to demand such behaviour from their contributors and members.

The IOM report explicitly rejects the suggestion that random data audits should be carried out in basic research. Rubenstein explains that the nature of basic research makes it nearly impossible to trace all the steps from data collection to tabulation and presentation, steps that can change as circumstances and new discoveries dictate. Such audits are more appropriate to clinical and protocol based research, where they are already used.

Meanwhile, NIH is urged not only to establish an office to encourage proper conduct, but to require by 1992 all institutions in receipt of grants to show that they have addressed the issue.

The report also suggests that NIH should limit the number of publications considered as part of a grant application to ease the temptation to produce inappropriately voluminous *curricula vitae*.

Rubenstein says the research community is now more open to suggestions that questions of conduct should be tackled, but he expects that there will at first be resistance to the proposal that there should be special panels for addressing questions of proper conduct. He believes the initial resistance will subside when researchers see that panels can improve the research climate.

NIH deputy director William Raub says the institutes, together with the Department of Health and Human Services, are already discussing the creation of an office of scientific integrity that could fill the role recommended by the IOM report, as well as investigating charges of misconduct. Raub says a crucial issue to be settled is where the office should be placed in the federal bureaucracy. The four possibilities being discussed are the Office of the NIH Director, the Office of the Assistant Secretary for Health, the Office of the Secretary of Health and Human Services (HHS) and the Office of the Inspector General at HHS.

The last of these options is the least favoured because the inspector-general's staff lacks scientific expertise. A final decision is bound to wait on a resolution of the political question when the position of secretary of HHS is filled. President Bush's candidate is still waiting confirmation by the US Senate.

Although the IOM report focuses on biomedical research, it recommends that the National Academy of Sciences look into the relevance of its findings for other scientific disciplines. **Joseph Palca**

US congress scuttles federal agency salary increases

Washington

THE US Congress voted last week to scuttle a 50 per cent pay increase it had been offered, and thereby perpetuated a problem with which federal agencies employing highly qualified professional staff have been struggling for some time. The National Institutes of Health (NIH) is among the most outspoken of the agencies affected.

NIH claim that their ability to recruit and retain able researchers has long been compromised by federal salary scales well below those applying at universities and in industry. The federal pay rise, which at first seemed certain to pass, would have applied to senior researchers and administrators at NIH and would, according to officials, have solved an old problem.

The proferred salary increase, recommended by an independent commission reporting every four years and endorsed by former president Ronald Reagan, would have taken effect automatically at 12:01 am on 8 February unless both the House of Representatives and the Senate had passed resolutions to reject it. The Senate did vote against the rise, but the House of Representatives had at first planned to let the deadline pass without taking action. But a huge public outcry against the proposal seems to have forced a vote — in the circumstances, inevitably negative.

After the vote, Senator Ted Stevens (Republican, Alaska) lambasted Congress for being unwilling to take the political heat for approving its own pay raise, a move that "penalizes other portions of the federal government", in particular NIH. Unlike most government laboratories, which are run by contractors who are not bound by federal pay scales, NIH researchers are federal employees.

NIH Deputy Director William Raub says that in the past ten years the number of NIH employees at the senior executive level has decreased by 28 per cent to the present 174 people. During the same period, NIH have not been able to recruit a single person from outside the institutes. Some of the decrease is due to retirement but Raub maintains many scientists have left for higher paying positions outside government. As an example, he says that senior executive service physicians receive on average $89,000 a year, only half the average supplemented salary paid to chairmen of clinical science departments at universities.

An independent committee of the Institute of Medicine, in a report issued last year (*Nature* **336**, 701; 1988), agreed that there is a serious problem at the senior level and suggested two remedies — the establishment of an NIH foundation to finance chairs for distinguished scientists, whose salaries would then be independent of government pay scales, and the creation of a personnel demonstration project within NIH that would allow more flexible hiring and remuneration.

Raub says the committee's report is "right on the mark". Now that Congress has rejected the pay rise, NIH are looking at the report's suggestions in more detail, but cannot hope to follow them quickly because that would require that a reluctantly self-denying Congress should pass new legislation to give others the benefits of which it has been robbed.

India's troubled space plans receive unexpected French boost

New Delhi & Paris

FRANCE last week signed bilateral agreements with India in the life sciences and agreed to help with India's troubled rocket programme and to strengthen nuclear ties between the two countries. The agreement on nuclear power would permit the French company Framatome to build two 900-MW light-water nuclear reactors in India provided that India agreed to use them for peaceful purposes only.

In the space arena, France has offered assistance for India's launch vehicle programme, which has been lagging after two successive mishaps. Hubert Curien, France's minister for research and technology, says immediate assistance can be given on the technology for clustering rocket engines, but a request for help with cryogenic motors may be delayed because of its commercial implications.

Curien says France could still provide this technology in consultation with its European partners if India agreed not to put the technology to military use and avoid any future competition with Arianespace in the international launch business.

According to the terms of the life sciences agreement, a joint venture company will produce six different vaccines using the technology supplied by Institut Marieux, which will hold 25 per cent of the company's share capital. The vaccine plant, to be built at Gurgaon near New Delhi, will start commercial production in 1991.

Defence cooperation was not on Mitterrand's agenda because the subject had already been discussed during the visit of the French defence minister in December 1988. France is said to have offered a $2,000 million package for collaboration that includes a contract for the design of India's third aircraft carrier, the supply of an advanced jet trainer, air-to-air missiles and anti-tank helicopters. Avions Marcel Dassault of France has been hired as a design consultant for the light combat aircraft India is building.

The French cultural festival in India that prompted Mitterrand's visit had a marked edge of high technology, as was evident from the inaugural show — a spectacular extravaganza in Bombay's Chowpathy Bay. Thousands of Indians, in the company of Mitterrand and Prime Minister Rajiv Gandhi, watched the bay reverberate to amplified music, with giant water screens providing the backdrop for eerie images — fusions of art and science — drawn by computer-controlled laser beams reflected from huge mirrors atop barges amid a massive display of pyrotechnics that set the night on fire. According to a French diplomat, the effort was worth it if it had helped to impress on Indians that France can offer something more than wine and cheese.

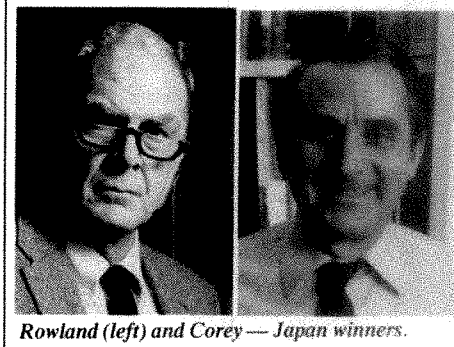
First report on US AIDS behaviour

Washington

THE first report* solely to address the behavioural aspects of the AIDS epidemic was released last week by a committee of social scientists organized by the US National Academy of Sciences. The committee decried the dearth of information available on sexual behaviour and intravenous drug abuse, and called for more studies to find viable ways of changing people's behaviour to lower their risk of infection with HIV, the virus causing AIDS.

The committee's report is the fourth major analysis of the AIDS problem to be conducted in the United States. The Academy and the Institute of Medicine teamed up in 1986 and again last year to offer their assessment of how to counter the epidemic, and the presidential commission on the HIV epidemic issued a laundry list of about 575 specific recommendations last year. Although some of the recommendations in these reports have been implemented, more controversial steps such as anti-discrimination legislation and random blood testing for HIV antibodies have been snarled in political battles.



The Academy committee recommends more systematic studies of human sexual practices and drug abuse patterns. Committee chairman Lincoln E. Moses from Standford University says "AIDS is a social disease", and that not enough effort has so far been put into studying the behaviours that put people at risk and learning how best to motivate them to change. The committee also recommended anonymous blood testing of all newborns.

Marshall H. Becker, from the School of Public Health of the University of Michigan, says the "Just Say No" approach favoured by the Reagan Administration is not working, and that more practical approaches for reducing risk must be used. Among the committee's recommendations for encouraging behaviour changes are expanded sex education for teenagers, condom advertising on television, and free distribution of needles to drug addicts until they enter treatment programmes. **AIDS: Sexual Behaviour and Intravenous Drug Use*, available from the National Academy Press, Washington, DC, 1989.

Japan prize awards

THIS year's Japan prize has been awarded to two US chemists working in different fields. The ¥50 million ($400,000) awards will go to F. Sherwood Rowland, an atmospheric chemist at the University of California at Irvine, and to Elias James Corey, an organic chemist at Harvard University. They will be presented on 12 April in Tokyo.

Rowland (left) and Corey — Japan winners.

Rowland is recognized for establishing that chlorofluorocarbons (CFCs) can destroy ozone in the stratosphere (see *Nature* **249**, 810; 1974). He predicted that if CFCs were to continue to be released into the atmosphere at 1974 rates, there would be a 7–13 per cent depletion of total ozone. Corey's award is for his contributions to the synthesis of prostaglandins.

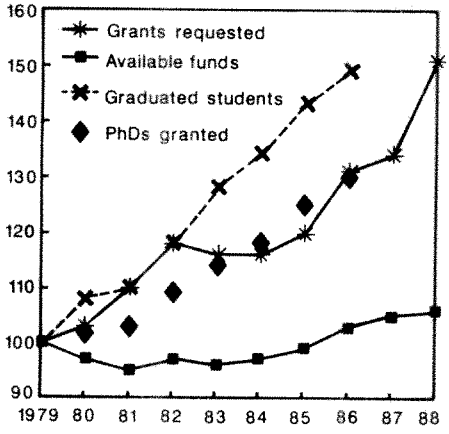
The Japan prize is awarded each year in two predetermined categories. This year's categories were medicinal science and environmental science and technology. Next year's will be for the technology of integration and for Earth sciences. J.P.

Peking man safe?

THE municipal government of Beijing (Peking) has introduced regulations to protect the site, now in the suburbs of the city, where the remains of Peking man were found. Under the new regulations all activities are prohibited that may destroy the land-form, terrain and ecological environment, including mining, tree-felling, hunting and the construction of factories that could be a source of pollution. Illegal excavation or selling or buying fossils and remains are also prohibited. V.R.

EMBL *déjà vu*

LENNART Philipson, director of the European Molecular Biology Laboratory in Heidelberg, will continue in his post until 1995 rather than leave next year as originally intended.



Faced with the withdrawal of the only candidate to replace Philipson (see *Nature* 337, 397; 2 February 1989), the laboratory's council last week decided to extend Philipson's stay. His original appointment was from 1982 to 1987, which was then extended for only three years. As a condition of continuing in post beyond 1990, Philipson successfully insisted on a five-year reappointment. P.N.

West German agency launches early bid for more funds

Bonn

THE Deutsche Forschungsgemeinschaft (DFG) has scored an early success in its campaign for an increased budget. West German Education Minister Jürgen Möllemann (Free Democrat) announced last Friday that he will campaign for a 5 per cent annual increase for DFG, the chief source of research grants in West Germany, in each of the next 5 years.

The proposed increase is by no means a certainty, since all eleven *Länder* (states) must first approve it. On the federal level, Möllemann must secure the support of the rest of Chancellor Helmut Kohl's cabinet. Three-fifths of DFG's support comes from the federal government and the rest from the *Länder*. Asked about the chances of success, Möllemann said that an annual increase of 5 per cent is "realistic and achievable". The agency's budget this year is DM1,188, but the 1990 budget will not be finally approved until December.

Grants requested and funds available from the DFG to 1988. The 1979 figures are taken as 100; no allowance is made for inflation.

DFG President Hubert Markl had sounded an alarm earlier last Friday when he declared that basic research support had "dramatically worsened" in 1988. He predicted grave consequences if DFG did not receive a 6.5 per cent increase in 1990.

The nub of Markl's case is that, in 1988, DFG had to reject the highest percentage of grant applications in its history: only 48.4 per cent of individual applications were funded. And for the first time, fewer than half of the *Schwerpunktprogrammen* (priority programmes) applied for could be supported (see *Nature* **336**, 510; 1988).

Part of the difficulty is that research is booming at West German universities, so that there are more applications for grants than ever. Markl expects even more competition for DFG funds in the future: 40 applications have already arrived for *Sonderforschungsbereichen* (special collaborative programmes), half of them planned to begin before 1990.

There are also more students than ever crowding West German universities, which Markl says will be looking to DFG to support graduate and postdoctoral studies for the next decade. Markl says that if these people are forced out for lack of funds, their potential will be lost.

One consequence of the high rejection rate is the disaffection of DFG's (unpaid) referees, who Markl says are "fed up" with reviewing good proposals which are not supported. But he resists the suggestion that greater competition might enhance the quality of West German research: that point was reached years ago, he says, so that the applications now being turned down are of the highest quality. Markl is concerned that Wes Germany will be "left behind" if it doe not increase research support. He point to the planned 10 per cent increase of th budget of the US National Science Found ation and the similar increase for the cor responding body in Japan.

DFG received only a meagre increase i 1988, despite Markl's impassioned appea in June, which is why he has felt impelle to act earlier this year, writing to Kohl an the heads of the *Länder* in January. H was visibly pleased by Möllemann' announcement last Friday.

The proposed increase is likely to b discussed at the next conference of th heads of the *Länder* on 10 March. Well-of *Länder* such as Baden-Württemberg an Bavaria are expected to take up DFG' case, while Möllemann's announcemen will put political pressure on the others.

Steven Dickma

Soviet psychiatrists at odds on eve of visit by United States

London

THE campaign by Soviet psychiatrists to rejoin the World Psychiatric Association may be impeded by an open letter to the Soviet Academy of Medical Sciences by Dr Viktor Gingilis, head of the genetics laboratory of the Brain Research Institute at the All-Union Research Centre for Mental Health. The letter is a direct attack on the director of the institute at which Gingilis works, Dr Marat E. Vartanyan.

As director of the Centre for Mental Health (since December 1987), Vartanyan is in a position to influence the practice of psychiatry in the Soviet Union. The letter, first circulated at the end of last November, comes on the eve of the beginning next week of a 2-week tour of Soviet psychiatric hospitals by a group of 20 US psychiatrists and other experts.

The charges levelled against Vartanyan, who is known in the West for his categorical denials that sane but politically suspect persons were ever incarcerated in Soviet psychiatric hospitals, include many of a personal nature. But Gingilis's general complaint is that Vartanyan is seeking to shift onto others his own burden of responsibility for a practice in which he was "most active".

Reached by telephone at the institute, Gingilis acknowledged authorship of the letter, but said that he himself had not sent it abroad or to the media. Asked whether, in that case, he would prefer *Nature* not to report it, he replied "That's your affair".

Vartanyan was not available for comment, being about to leave on a business trip. His assistant, Dr Georgii Morozov, said, however, that Vartanyan knew all about the letter, and thought it a matter of little importance. "If Dr Vartanyan could speak to you, he would explain itall", Morozov said. An arrangement tha Vartanyan would call *Nature* back at an agreed time failed to materialize.

Gingilis says that Vartanyan's election to his present post (necessary under the new democratization) was rigged, and went against the wishes of the majority of the centre's staff. His letter goes on to suggest that Vartanyan and his wife, D. D Orlovskaya (who is at the same institute) have risen in academic distinction on the strength of the work of others, many of whom have subsequently been hounded into resignation or emigration. The letter says "I am the real author of almost all the publications and research initiatives attributed to M.E. Vartanyan in the field of medical genetics".

Gingilis claims that his own work, together with that of I. V. Shakhmatova-Pavlova, was misappropriated by Vartanyan to support his appointment as corresponding member of the Soviet Academy of Medical Sciences. He says that Vartanyan's personal power base has remained secure because few have been prepared to speak up in public, but "after twenty years of serf-like dependency on Vartanyan", he has decided to speak out "with all responsibility and with a clear understanding of the possible consequences".

It remains to be seen what will be the effect of this letter on next week's visit by the US group. The Soviet authorities maintain that all dissidents have either now been released, or are being processed for release, from psychiatric hospitals. The visitors will be able to examine patients whom they choose and to visit at short notice psychiatric hospitals which they select.

Vera Rich

Too high radon risks not helped by "penny-pinching" UK government

London

BRITISH safety limits for the concentration of radon gas in houses are too high and government proposals for financial help to those at risk are "penny-pinching and restrictive", according to the Institution of Environmental Health Officers (IEHO). The institution is the professional organization of environmental safety officers employed by local governments. Its criticisms of government policy appear in a report published two weeks ago.

The key recommendation is that the radon dose at which remedial action is considered to be necessary should be

halved, from 400 to 200 becquerels per m^3. This concentration was fixed two years ago by the National Radiological Protection Board (NRPB), when it was estimated that the lifetime risk of lung cancer after chronic exposure to 400 Bq per m^3 would be between 2.0 and 2.5 per cent.

The NRPB now estimates the lifetime risk to be 5 per cent, and the environmental health officers say that, as a result, the action level should be halved. The NRPB is now reviewing its safety levels. But Michael O'Riordan of the board says the level will not automatically be halved: the cost of taking remedial action and the available technology will be taken into consideration before a decision is made.

Only in the United States is the action level lower than in Britain: the Environmental Protection Agency (EPA) recommends an action level of 150 Bq per m^3. The agency would like this to be reduced by a factor of 10, at which point the radon concentrations indoors would be equivalent to those outdoors. But in practice it may only be possible to halve the present action level, says a spokesman. About 8 million homes, 10 per cent of the US total, are estimated to have concentrations of radon above the action level. The most common way of tackling the problem is to "poke a hole in the floor of your basement, put a pipe in, run it through the ceiling and put a fan on the top", according to an EPA spokesman. This can cost between $200 and $1,500. The EPA is carrying out a survey to find out how many take the necessary action.

In the European Communities, no country other than Britain has any safety levels for radon concentration in the home. But the European Commission is considering recommending that member countries adopt the British standards. Sweden and Finland, the only other European countries with safety levels, set the action level at 800 Bq per m^3.

The IEHO report puts the number of houses in Britain with radon levels above the present action level at 50,000, which is also twice the number estimated by NRPB. As well as the halving of the action level for which it asks, the institution says that the "priority action" concentration should be reduced from 1,000 to 800 Bq per m^3 and that the "investigation" concentration should be reduced from 200 to 100 Bq per m^3.

The report is especially critical of a government document giving guidance to local authorities on home improvement grants to those potentially at risk. The government expects most owners to bear the cost of remedial action themselves, but Martin Courtis, the report's author, says that if house owners are not offered a grant of at least 75 per cent of the cost of remedial work, there is little, if any, prospect that the radon problem in Britain will be tackled. **Christine McGourty**

Computer microcode instructions judged within copyright

Berkeley

A Californian court last week declared that microcode instructions on microprocessor chips can be protected by copyright. The decision, expected to be a landmark for microprocessor manufacturers, is likely to deter outright copying of microprocessor design.

Although computer programs were added to the US Copyright Act by Congress in 1980, the status of microcode — the set of instructions determining how a processor's components will perform a specific function — was unclear. As with any other program, a variety of instruction sets could be devised to achieve the same goal. Last week's ruling puts microcode "squarely within the definition of 'computer program'", and therefore subject to copyright protection.

The ruling also ends a 7-year dispute between Intel Corporation, of California, and NEC Ltd, of Japan. Intel claimed that NEC's 'V-series' of microprocessors infringe Intel's copyright of its 8086 and 8088 chips, used in the first generation of IBM personal computers. Although the court upheld Intel's right to copyright the microcode, it nonetheless absolved NEC of having violated that copyright, allowing both sides to claim victory in the case.

Intel and NEC entered into a general patent cross-licensing agreement in 1976 giving each access to the other's patents. The copyright dispute arose after Intel introduced the 8086 and 8088 microprocessors in 1978, and NEC began producing identical copies of the chips under the cross-licensing agreement. Intel objected, arguing that the patent-sharing allowed NEC to produce a chip of similar function, but not to use the copyrighted microcode instructions contained in the chip. The matter was temporarily settled in 1983, when Intel licensed NEC to make the chips. Shortly afterwards, NEC developed its own 'V-series' of comparable microprocessors.

The first trial of the lawsuit was discontinued in 1986, when NEC objected that the judge owned a small amount of Intel stock. The judgement in the second trial, announced last week, declared that microcode can be protected by copyright, but found that NEC's microcode is sufficiently different from Intel's not to be a violation. Intel was also found to have forfeited its copyright by not requiring licensees to place notice of the copyright on their chips. NEC now has 11 per cent of the $7,000 million microprocessor market, compared with Intel's 26 per cent share, but NEC officials predict that the court's vindication of its practice will improve its sales.

But Intel is also claiming victory, as the decision is likely to discourage others from copying its microprocessor designs. The loss on the 8086 and 8088 chips is financially unimportant, say company officials, as the 10-year-old chips have been replaced in personal computers by second- and third-generation microprocessors. The 8086 and 8088 chips now account for only 1 per cent of total Intel sales, says company representative Pam Pollace. She also says that the more complex microcode of the second- and third-generation 80286 and 80386 microprocessors will be much more difficult to approximate except by outright copying, which would clearly infringe Intel's copyright. **Marcia Barinaga**

Oil-spill danger to nesting birds

Berkeley

A US oil cleanup crew last week reached the Antarctic Peninsula and stemmed the flow of diesel fuel from the wrecked Argentine supply ship *Bahia Paraiso*, which ran aground on 28 January near the US Palmer Base. The ship had already spilled two-thirds of its 250,000-gallon fuel supply. While the US team skimmed most of the recoverable fuel from the surrounding waters, an Argentine salvage crew prepared to remove the remaining 75,000 gallons of fuel remaining on the ship.

The biological consequences of the accident are now being evaluated. Unrecovered fuel has collected in shallow coves and inlets, where it has killed intertidal limpets, sponges and kelp, says Bernhard Lettau, National Science Foundation (NSF) programme manager for Polar Ocean Sciences, who recently arrived at the site. Lettau says the bottom-dwelling community may escape serious harm, as the water is relatively clear and free from particulate matter that could carry the fuel to the bottom.

But oil slicks less than 1 mm thick cannot be removed by skimming, so that a diesel sheen remains on much of the water in the area, according to Thomas Forhan, an NSF project manager at the site. He says that all traces of the volatile fuel should be gone within 10 days to a month, barring further leaks.

Forhan says that the ship, which is on its side in 40 feet of water, is unlikely to break up soon and that the Argentine salvage operation may take 3 to 4 weeks to recover the remaining fuel. He notes that the recovery entails the risk of further spills.

The effects of the spill on the area's krill population are unclear, according to Lettau. Deep-water animals have been less badly affected than shallow-water ones. But the spill has had a devastating impact on bird populations nesting near Palmer Base. Lettau says the breeding success of the South Polar skuas in the area "will be zero". Skuas lay two eggs in each nest, and usually only one chick survives to fledge.

But out of 53 nests inspected, only 6 had a living chick last week, and Lettau expects none of these to survive. He is unsure of the cause of death, but speculates that the chicks may be getting toxic doses of fuel in the food brought by their parents.

Lettau expects that the toll will be greatest among young birds, including penguin chicks, which fledge and take to the water in early February. Researchers at the base have begun banding chicks that have not yet left their rookeries, so as to trace their eventual fate. **Marcia Barinaga**

Japan grapples with definition of death by brain death

Tokyo

THE twenty-year controversy over the definition of brain death has entered a new phase. Last week, the Japanese Diet (parliament) was presented with new legislation that will eventually decide when the absence of electrical activity in the brain (brain death) can be considered to define the death of a person. At stake is whether surgeons may legally perform life-saving heart and liver transplant operations — both of which require the donation of living organs from brain-dead people.
